SHAGREE'N is generally understood to mean shark skin dressed and rubbed down smooth or not; but the Oriental shagreen, formerly in so much repute, consists of portions of the skins of horses, asses, camels, and oxen, the part used being strips taken from head to tail along the center of the back. These strips are prepared by soaking in water and currying; and when in the proper condition, they are laid on the ground, and the seeds of *Chenopodium album* are sprinkled over them; a board or piece of felt is then placed on the seeds, and by pressure the hard seeds are forced deeply into the skin, which is then hung to dry. When dry, the seeds are removed by shaking, and the skin pared down with a proper knife nearly, but not quite as low, as the bottom of the depressions caused by the seeds. After this the skin is again soaked, and the parts compressed by the seeds now rise up and form elevations, which are increased by washing in a solution of salt. The last operation is dyeing them of various colors, green being the favorite one. Owing to the difference of texture produced by the operations of compressing by the seeds, paring, &c., the color, is taken irregularly; and when dyed green, the material somewhat resembles malachite in appearance when dried and polished. It was at one time a very favorite material in Britain for covering small cases and caskets of various kinds, especially spectacle-cases.

SHAH (Persian, *prince, king*), the general title of the supreme ruler in Persia, Afghanistan, and other countries of Southern and Central Asia. The sovereign, however, may, and frequently does, decline the title, assuming it its place that of *Khan* (q. v.), an inferior and more common appellation. The same title can also be assumed by any of the shah's sons, and upon all the princes of the blood the cognomen *Shah-zadeh* is bestowed.

SHAH-JEHAN, or 'King of the World,' the title assumed on his accession to the throne by Khorrum Shah, the third son of Selim Jehan-Ghir, and the fifth of the Mogul emperors of Delhi. He was during his father's reign employed in military expeditions against that Rajputs, the independent Mohammedan states of the Deccan, and the Afghan tribes around Candahar, in which he greatly distinguished himself by bravery and military skill; but on his return, he was forced into rebellion (1623) by the intrigues of his enemies at court, and was still unreconciled to his father at the latter's death in 1627, when he was at once saluted as emperor by the nobles. At his accession, the empire had reached the summit of its greatness, but the causes which led to its rapid decline at the same time unmistakably showed themselves: the territory was too extensive for the system of government which was generally pursued by the Moguls; the discordant parts were unconnected by any bond of union; the supreme ruler was looked upon in many provinces as a mere tax-collector; and with the thus necessary absence of any spirit of loyalty, insurrections were frequent in all the provinces. The chief events of S.-J.'s reign were—the war against the Deccan sovereignties, which resulted in the complete destruction of the kingdom of Ahmednuggur (1631), and the subjugation (1636) of those of Beejapur and Golconda; an indecisive contest against the Uzbeks of Balkh (1644—1647); two unsuccessful attempts to recover Candahar from the Persians; and a second successful war, conducted by his third son, Aurungzebe, against the Deccan princes (1655). But in 1657 the emperor fell dangerously ill, and his four sons, who were ambitious of attaining supreme power, immediately commenced to dispute regarding the succession. See AURUNGZEBE. Ultimately, S.-J. was taken prisoner, and confined in the citadel of Agra till his death, December 1666.

S.-J. united the voluptuous profligacy so common in Eastern monarchs with great sagacity, and the strict administration of justice to Moslem and Hindu alike. In his later years he became avaricious, increased the taxes, and confiscated the property of his wealthier subjects on the slightest pretexts. The magnificence of his court was unequalled; the splendid 'peacock-throne' was constructed by his orders at a cost of about £7,000,000, and many magnificent public buildings executed under his direction remain as monuments of his greatness. Chief of these are the city of Shahjehanabad, and the suberb mausoleum of Tajmahal (see AGRA). Yet so strict was his financial management, that he left a well-appointed army of 200,000, and a treasury containing £24,000,000 to his son Aurungzebe.

SHAHJEHANPO'RE, a town of British India, the principal place of a district of the same name, North-west Provinces. It stands on the Gurrah, a feeder of the Ramgunga, 94 miles north-west from Lucknow. Pop. (1872) 72,140.

SHAH NAMEH, Book of Kings, the title of several Eastern works, the most celebrated of which is the Persian poem of this name by Firdusi (q. v.), containing the history of the ancient Persian kings in about 60,000 distichs, and written by the order of Sultan Mahmud of Ghizni, in the space of thirty years. Another work, in Turkish, under the same name, comprises the history of all the ancient kings of the East, and was written by Firdusi Al-Thauil. Bajazet II., to whom the book was dedicated, ordered the author to reduce it from its original bulk of 300 volumes to 80. Firdusi, however, felt so mortified at this proposal, that he preferred leaving the country altogether, and emigrated to Khorassan, in Persia.

SHAKE, in Music, an embellishment produced by the continued and rapid repetition of one note alternately with another either a whole tone or semitone above it. Its sign is *tr* (the first two letters of the Italian *trillo*), placed over or under the principal note. For example:  , is played thus:

; the exact number of repetitions

being indefinite. A shake is often preceded by an Appogiatura (q.v), and is very generally finished with a turn, as  , played: . We may have shakes on two notes at once; and a series of shakes is called a chain of shakes.

SHAKERS, the name commonly given to a small religious sect existing in the United States of America. The proper or official description of this sect is the United Society of Believers in Christ's Second Appearing; but its members seem to have accepted the designation of Shakers, though it was originally applied to them in ridicule, on account of certain rhythmical movements of the hands and arms which form part of the ceremonial of their worship. Though the Shaker Societies are found only in the United States, their creed had an English origin. The founder of the sect, in whose person they believe that Christ has appeared a second time, was an Englishwoman, named Ann Lee, a native of Manchester, who emigrated to New York with a small band of disciples, shortly before the outbreak of the revolutionary war.

Ann Lee was the daughter of a blacksmith, who lived in Toad Lane in Manchester; a very poor man, who gave her no education, and sent her while a mere child to work in a cotton-mill. She seems to have been a violent, hysterical girl, ambitious of notice, and fond of power, and to have always possessed, in virtue of her strong will and vehement temper, a great deal of influence over the people around her. She married, while very young, a blacksmith named Stanley. She had four children, all of whom died in infancy—to this, perhaps, may be ascribed the preference of the celibate to the married life, which she ultimately raised into a part of her religious system. She became one of the earliest believers in a prophetess, who appeared about a hundred years ago, in the town of Bolton-on-the-Moors, in Lancashire—a poor woman, named Jane Wardlaw, the wife of a tailor, who believed she had 'received a call' to go forth and testify for the truth. The burden of Jane Wardlaw's message was, that the end of all things was at hand, that Christ was coming to reign upon the earth, and that his second appearance would be in the form of a woman, as prefigured in the Psalms. In subordination to this, she took up several of the tenets of the Society of Friends, to which she and her husband originally belonged; especially, she raised her voice against war and against profane swearing. Her followers believed that she was filled with the Holy Spirit; they received her utterances as the voice of God; and she acted as if all the powers of earth and heaven had been given into her hands. Ann Lee, on her conversion, began to preach the same message in Toad Lane and the adjacent streets of Manchester; but she soon went beyond her teacher, and gained the leadership of her co-believers for herself. It happened that she was brought before a magistrate, charged with an obstruction of the streets, caused by the crowd collected to hear her preach, and she was sent to the Old Bailey Prison in Manchester.

When she came out of prison, she gave forth, that one night a light had shone upon her in her cell; that the Lord Jesus stood before her; and that He became one with her in form and spirit. Her pretension was, that Christ was come to reign in her person. It was favorably entertained by the followers of Jane Wardlaw; and they acknowledged her as their Head, or Mother, in place of Jane, whose pretensions had never gone so far. She found, however, that among her neighbors and fellow-workers, her claim to be the Bride of the Lamb, the Queen described by David in the Psalms, excited only jeering and ridicule; and she received a revelation that she should seek in America a home for herself and her few disciples—that it was in America that the foundations of Christ's kingdom were to be laid. So she went to New York, accompanied by seven disciples—five males and two females. Her husband also went with her; but he seems to have had no faith in her, and he left her soon after their arrival, in consequence of one of the features then introduced into her system. This was the practice of celibacy, which she had not previously enforced upon her followers, though she had enjoined it as a duty. Her teaching was, that men called into grace must live as the angels do, among whom there is no marrying or giving in marriage; that no form of earthly love could be allowed in the Redeemer's kingdom. Finding a populous city unfavorable to her designs, she removed, with her followers, first to Albany, then far into the wilderness to Niskenna, and there founded the settlement which still exists, of Water Vliet. It was in the spring of 1780—when she had been three years and a half at Niskenna, looking for new believers to come in, but making no attempt to win them—that the first American converts joined her society.

A revival had taken place at Albany, and had spread through the surrounding districts; and from Hancock and New Lebanon a deputation was sent to Niskenna, to see what light its inhabitants enjoyed as to the way of salvation. The deputation consisted of Joseph Meacham and Lucy Wright—subsequently the heads of the Shaker Society. These persons became believers in Ann Lee; and through their agency, other converts were won, and a Shaker Society established at New Lebanon. Towards the close of 1780, the revolutionary war being then in progress, notoriety was given to Ann Lee's pretensions, through an incident seemingly unfavorable. Owing to her British origin, her denunciations against war, and her refusal to take the colonial oaths, Ann was imprisoned for some time at Poughkeepsie, on suspicion of being a British spy. Before she was let out of prison, in December 1780, all the colonies had heard of 'the female Christ.' In the following year, she started upon a missionary tour through New England and adjacent colonies; she found the people everywhere curious to see her, and she made not a few converts. She did not return to Water Vliet till September 1783; and about a year after, she died. Her death was a surprise to many of her followers, who believed that she was to live among them forever; but her successors—the Joseph Meacham and Lucy Wright already mentioned—to whom, on her death-bed, she had made over the headship of the Society, were ready with a theory accounting for it. 'Mother Ann,' they said, could not die, and was not dead, and had not ceased to live among her people. She had only withdrawn from the common sight; she was still visible to eyes exalted by the gift of grace; she had cast the dress of flesh, and was now clothed with a glory which concealed her from the world. So it would be with every one of the saints in turn; but the spirits of those who 'passed out of sight' would remain near and be in union with the visible body of believers. This explanation was generally accepted, and has become a vital part of the Shaker creed.

By Joseph Meacham and Lucy Wright, the successors of 'Mother Ann,' the S. were gathered into settlements, ten in number; and a covenant was drawn up embracing the chief points of their creed, and of the social system since associated with it. Their head was, of course, 'Mother Ann'—that is, Christ—of whom Joseph and Lucy were temporarily the representatives; elders, and deacons, male and female, were appointed; the institution of celibacy was confirmed; and a community of goods was introduced. On the death of Joseph Meacham in 1796, 'Mother Lucy' became the sole head of the Society, and she governed it with ample powers for 25 years. She named a female successor with the title of Elderess; and the name of 'Mother' has not, since that time, been applied to the female head of the community. Eleven societies were formed between 1787 and 1792. Early in the present century, a remarkable religious excitement took place in Kentucky. The Shakers, taking advantage of this movement, sent three representatives thither, and received sufficient additions to found five new societies. (See Nordoff's *Communistic Societies of the United States*, 1875.) The S. were, at the census of 1870, about 2500 in number, included in 18 societies; of which three are in the state of New York, four in Massachusetts, two in New Hampshire, two in Maine, one in Connecticut, four in Ohio, and two in Kentucky. Their numbers have increased since 1870; the influence of their opinions has extended; and the 18 separate settlements continue to form a united and peaceful Society.

Their doctrine has been to some extent developed as well as systematized since the death of 'Mother Ann.' They believe that the kingdom of heaven has come; that Christ has come upon earth a second time, in the form of 'Mother Ann,' and that the personal rule of God has been restored. Then they hold that the old law has been abolished, and a new dispensation begun; that Adam's sin has been atoned; that man has been made free of all errors except his own; that the curse has been taken away from labor; that the earth and all that is on it will be redeemed. Believers, on going 'into union,' die to the world, and enter upon a new life, which is not a mere change of life, but a new order of being. For them, there is neither death nor marriage; what seems death is only a change of form, a transfiguration which does not hide them from the purified eyes of the saints; and in union, as in heaven, there is no marrying or giving in marriage—the believer owes love to all the saints, but his love must be celibate in spirit and in fact. The believer, living in union, *is* in heaven. The S. believe that the earth, now freed from the curse of Adam, is heaven; they look for no resurrection besides that involved in living with them in 'resurrection order.' The believer, upon entering into union, leaves behind all his earthly relationships and interests, just as if he had been severed from them by death. And since to be in union is heaven, the S. hold that no attempts should be made by them to draw men into union: God, they say, will draw to them those whom he has chosen at his own time. Those who have 'passed out of sight' are still in union; and the S. live in daily communion with the spirits of the departed believers.

The belief in a communion with angels and spirits, is no mere theory; it has a most important influence upon their lives; they profess to be more familiar with the dead than with the living. It being the work of the saints to redeem the earth from the effects of the curse, labor is a sacred and priestly function, especially when bestowed in making the earth yield her increase, and in developing her beauty. It should be done in a spirit of love; the earth, they say, yields most to those who love it; and love and labor will in time restore it to its primitive state. According to Mr. Dixon, they bestow upon their gardens and fields the affections which other men bestow upon family or worldly goods. Their country they regard only as it is a part of the earth, which they love, and as the favored land in which God's kingdom is first to be established. In its politics and its fortunes, they take no interest; and, indeed, their whole system is a protest against the existing constitution of society, as well as against the ordinary lives of men. Consistently with their belief in the second appearance of Christ in the form of a woman, the S. seem to believe that there is a female as well as a male essence in the Godhead—in the motherhood as well as the fatherhood of God.

A Shaker settlement is, for convenience, divided into families, consisting of the brothers and sisters, who live in the same houses, each governed by an elder and an elderess. There are two orders of members, Probationers and Covenanters—that is, novices and full members. It is on becoming a covenanter that the Shaker puts his property into the common stock. On entering upon residence, he becomes subject to all the rules of the Society; but he is free—whether a covenanter or a probationer—to leave the body whenever he pleases. Both men and women wear a prescribed dress. The men wear a sort of Arab sack, with a linen collar and no tie; an under-vest buttoned to the throat, and falling below the thighs; loose trousers, rather short; and a broad-brimmed hat, usually of straw. The women wear a small muslin cap, a white kerchief round the chest and shoulders, a skirt dropping in a straight line from the waist to the ankle, white socks, and shoes. Some latitude is allowed as to the materials of the dress.

Men and women, it is said, have the look of persons at peace with earth and Heaven. 'Apart from a costume,' says Mr. Hepworth Dixon, 'neither rich in color nor comely in make, the sisters have an air of sweetness and repose, which falls upon the spirit like music shaken out from our village bells.' [*New America*, by W. Hepworth Dixon (Lond. 1867), from which the materials of this sketch have in a great measure been derived.] All labor with their hands, both men and women; but the latter do only indoor work. Every man, whatever his rank in the church, follows some manual occupation, and most of them have more than one. Working not for gain, but with loving care, and with the sense that they are exercising a priestly function, the S. are unrivalled among their neighbors in the arts to which they apply themselves, especially the culture of their land, and the production of fruits and flowers. They pay great attention to ventilation and to all sanitary conditions; they live almost entirely upon the produce of the soil, and drink only water; they employ no doctors, and take no drugs and are, nevertheless, among the healthiest of communities. Their Society is recruited mostly by young men and girls; but occasionally married persons with their children come 'into union,' and make, it is said, 'very pretty Shakers.' Husbands and wives, when they have come 'into union,' become as brothers and sisters: it would be thought a weakness, says Mr. Dixon, and almost a sin, for them to feel any personal happiness in each other's company—they live for God alone, and their love ought to be shed on all the saints alike. The education of the children attached to the Society is the work of the sisters, and they do it exceedingly well. The brothers and sisters take their meals in a common room, eating at six in the morning, at noon, and at six in the afternoon. Their meals are taken in silence, any direction that has to be given being given by a gesture or in a whisper. In their church-service, music bears a prominent part; the hymns and chants which are used being all of Shaker origin, communicated to believers in dreams and reveries by the spirits with whom they have communion. A deputation of Shakers visited England in 1871, and made many converts.

SHAKSPEARE, WILLIAM, the chief literary glory of England, was born at Stratford-on-Avon, in Warwickshire, it is believed, 23d April 1564. Certain it is, as vouched by the parish register, that his baptism took place three days after, on the 26th. His father, John Shakspeare, seems to have belonged by birth to the class of yeomen. His mother, Mary Arden, was of more distinguished origin. She came of a good old Warwickshire family; and when married, she brought to her husband as dower a property called Asbies, 54 acres in extent, besides an interest in certain other lands at Wilmecote, and a small sum of money. In a contemporary document, John Shakspeare is described as a *glover;* and this trade, at that time a more important one than it has since become, there is evidence to show that he conjoined with that of a farmer and rearer of stock. His earlier career was one of steady prosperity, and the consideration in which he came to be held as a citizen, is shown in the fact of his having, in 1569, been elected chief magistrate of Stratford. Of a family of four sons and four daughters born to him, William was the third child. At the free grammar-school of Stratford there can be little doubt the young S. received his entire education. As to the precise character and amount of this, there has been much controversial conjecture; some writers maintaining, on the internal evidence of his works, that he must have enjoyed a thorough classical training, whilst others represent him as probably destitute of any such youthful advantage. The celebated 'And though thou hadst small Latin and less Greek' of his friend Ben Jonson, which has been frequently quoted as certifying his almost utter ignorance, seems, if anything, to tell the other way. It assures us that, of both languages, he knew something; as to *how much* of either he may have known, it affords us scarce a ray of light, inasmuch as it is impossible for us even to guess at the amount of classical attainment sufficient, in the eyes of a scholar, and something of a pedant, like Jonson, to entitle a man to the praise of having *much* Latin and Greek. What Ben might contemptuously style 'small Latin' was, in all probability, as it seems to us, a fair working allowance of it.

Meantime, misfortune had overtaken, and more and more come to press heavily on John Shakspeare; in consequence of which, William, now somewhat over fourteen, was withdrawn from school, and set to do something for his living. How he was employed from this time till his departure for London, it is impossible to make out with distinctness. One tradition informs us, that, for a time, he served as apprentice to a butcher; and it is said that, 'when he killed a calf,' the poetry of his nature prompted him to ennoble the operation as he could to himself, by 'doing it in a high style, and making a speech.' Unhappily, none of his speeches have come down to us, so that rather more of a mythical atmosphere than might be wished surrounds this pursuit of the ideal under difficulties. But that he was for some time a butcher's assistant, is as likely to be true as not. Another story has it, that for some years he was a schoolmaster; whether or not in birching his boys he dignified the act as in the calf's case, tradition has omitted to inform us. Both stories are not unlikely to be true; the fact of the matter probably was, that in those years young S. lived miscellaneously as he could. Out of the cloud of uncertainty which shrouds this period of his life, two facts, however, emerge as beyond question—his marriage, and the birth of his eldest born. As soon as may be after the 28th November 1582—on which day the license was procured at Worcester—Shakspeare, a lively lad going nineteen, was married to Anne Hathaway of Shottery, a hamlet some mile or so out of Stratford, a damsel about eight years older than himself; and six months afterwards a daughter was born to him, whose baptism bears record 26th May 1583. The obvious inference from this promptitude on the part of his spouse certain of his admirers have sought to evade. It is said, and we believe it is certain, that a mere betrothal before witnesses, to be followed within some reasonable undefined period by the religious ceremony, was then and there held to constitute a valid marriage; and this, it is conjectured, may in S.'s case have prefaced the more formal sanction. And of course it may; the license of conjecture is unlimited; and all to whose comfort in admiring a great genius it is essential to regard him at every point of his career as also a pattern of everthing that is proper, must of course be made welcome to this one. The only other children born of the marriage were twins, a boy and a girl, baptized 2d February 1585. The boy (Hamnet) did not survive his father, dying in his twelfth year.

As nearly as can be made out, in the year 1586, S., then 22, left the neighborhood of Stratford, and betook himself to London. A local tradition assigns as his reason for doing so a mishap which befel him, and a little imprudence consequent on it. The future poet, it is said, while out on a nocturnal poaching expedition in the deer-park of a neighboring magnate, Sir Thomas Lucy of Charlecote, was caught by the keepers, kept for the night a prisoner, and arraigned before Sir Thomas—a justice of peace—in the morning. What passed, is not recorded; but—as the old rumor goes—whatever it was, it excited the ire of S., who avenged himself, as a bard naturally might, by circulating 'a bitter ballad' in which the good knight was satirized. A further prosecution was for this irreverence directed against him, to escape which it was that he is said to have fled to London. No anecdote concerning S. has been more widely accepted than this, or, on the whole, seems better to deserve acceptance. An obvious allusion to the Lucies of Charlecote in the *Merry Wives of Windsor*, which identifies their coat of arms with that of Justice Shallow, would of itself afford strong confirmation of it. Further, Oldys, an antiquary who died in 1761, and had busied himself much about materials for a life of S., certifies the story on something like fair evidence, and gives the first verse of the obnoxious pasquinade, as remembered in the district. It is more coarse and scurrilous than witty; but inasmuch as it would be easy to adduce passages from

the admitted writings of S., in which the coarseness to at least an equal extent preponderates over the wit, this will scarcely of itself amount to proof that he could not possibly have been its perpetrator. The indisposition which more lately has been shown to attach any credit to the tale, seems to rest entirely on a foolish horror of admitting anything as possible in the conduct of the poet which might any way seem to conflict with the reverence now universally accorded to his genius.

No certain details have come down to us as to S.'s earlier relations with the London theater. According to one tradition, he was content at first to turn a penny by holding horses at the door. According to another—which seems in a natural sequence with the foregoing—we find him admitted inside on his promotion, though as yet only in the humble capacity of prompter's attendant. What is certain in the matter is this, that if at any time he was thus meanly occupied, it could have been only for a brief period, as very speedily we have note of him as a man of some importance, at once dramatist, actor, and shareholder in the Blackfriars Theater. As an actor—though we find one contemporary allusion to him as 'excellent in the quality he professes'—he seems at no time to have shone especially, being rather respectable than eminent. As dramatist, his magnificent powers were at once recognized, and in no long time had won for him the very foremost rank among the writers for the stage of his time. The extraordinary rapidity of his rise is shown in this indubitable reference to him in Spenser's *Tears of the Muses*, published so early as 1591, only some five years after S.'s arrival in London:

> And he, the man whom Nature's self had made
> To mock herself, and truth to imitate,
> With kindly counter under mimic shade,
> Our pleasant Willy, ah, is dead of late.

The reference here has indeed been surmised to point at Sir Philip Sidney, by Spenser elsewhere alluded to under the figure of Willy a shepherd; but the surmise is, on various grounds, inadmissable. The first two lines have the closest critical pertinence to the character of S.'s genius; as applied to that of Sidney, they are, by comparison, vague and unmeaning. Further, the 'mimic shade' in the third line, together with the whole context of the passage, makes it certain a dramatic writer is alluded to; and this Sidney was not.

Moreover, the stanza which follows, wherein of 'that same gentle spirit' it is said that he

> Doth rather choose to sit in idle cell,
> Than so himself to mockery to sell,

must needs be held to indicate a man at the time living; and Sidney had died in 1586. The 'Ah, is dead of late!' which, literally taken, would suit Sidney, and not S., must, in the light of the succeeding couplet, be interpreted as referring to some temporary remission on the part of the latter of his wonted dramatic productiveness; and this, if not otherwise to be accounted for, we might explain by supposing him at this time engaged on his two elaborate poems, *Venus and Adonis*, and *The Rape of Lucrece*, published not long afterwards. The year after (1592), we find a contemporary and brother dramatist, Henry Chettle, making the *amende* to S. for an offence given, in terms most respectfully appreciatory of his excellences at once as a man and an author; and in 1598, Francis Meres, in his *Wit's Treasury*, writes of him as admittedly the 'most excellent among the English for both kinds of tragedy and comedy.' We have ample evidence besides of the unrivalled acceptance his works obtained from all classes; not only were they in the wider sense popular, but they brought him special marks of favor and approval from Queen Elizabeth and her successor, James—who is said to have honored the poet with an 'amicable letter' from his own hand—and procured him the patronage and friendship of some of the most accomplished men of rank of the time, more notably, Henry Wriothesley, Earl of Southampton, to whom he dedicated his *Venus and Adonis*, and *Rape of Lucrece;* and William Herbert, Earl of Pembroke, commonly held to be the 'Mr. W. H.' to whom, as their 'only begetter,' his *Sonnets* are addressed.

S. was plainly—as men of *consummate* genius mostly are—a man of shrewd solid business ability; and throughout, his material prosperity kept pace with the growth of his poetical reputation. He became early, as we saw, a considerable shareholder in the Blackfriars Theater. In the Globe, subsequently erected, he was also a part proprietor. To both he contributed dramas, and from his gains in the triple capacity of actor, author, and sharer of the general profits, he rapidly amassed a fortune. His local attachments were strong, and it seems to have become, as his wealth increased, one main object of his ambition to settle himself as a substantial country gentleman in his native district, to which annually he made a visit. We find him, with this view, from time to time making purchases there of house and landed property. By and by, his visits to Stratford became more and more frequent; and it is positively certain that previous to the year 1613, he had ceased to reside in London, and finally established himself at Stratford. Of his last years there spent, further than that they lapsed peacefully in honor, and the exercise of a liberal and kindly hospitality, nearly nothing is known. There is evidence of his having more or less occupied himself in agricultural pursuits, and good reason to believe that, though withdrawn from other active concernment with the stage, he still continued to write for it. His death took place on his 53d birthday, the 23d April 1616. In the diary of a Mr. Ward, the vicar of Stratford, writing *apud* 1660, the cause of it is thus given: 'Shakspeare, Drayton, and Ben Jonson had a merry meeting, and, it seems, drank too hard, for Shakspeare died of a fever then contracted;' but that of this drinking the poet's death was a consequence is at best a doubtful inference.

That S. erred and sinned at times like others, we know from the passionate confessions of his *Sonnets*, in considerable portions of which the self-reference is too plain to be denied; but that, whatever his occasional frailties, he was essentially a man of noble and estimable character, there is a complete concurrence of testimony. He was obviously of most kindly and lovable dispositions; his 'pleasurable wit and good nature' made him delightful as a companion; and it was as 'gentle Will Shakspeare' that he was familiarly known to his contemporaries. In particular, with his associates and rivals in writing for the stage, his relations would seem to have been of the most cordial and even endearing kind. The gruff Ben Jonson writes of him after his death: 'He was honest, and of an open and free nature,' assures us that in 'his well-turned and true-filed lines' we see but an authentic reflex of his beautiful 'mind and manners;' and avers that he 'honors his memory only on this side idolatry.' As a slight shadow on this pleasing picture, it has been shrewdly surmised that he was not very happy with his wife. Evidence of this has been sought in certain passages in his dramas; but obviously any inference from these is most precarious. The neglect of her in his will, except in one curt clause interlined, dismissing her with a legacy of 'his second-best bed,' might well seem much more decisive, till Mr. Charles Knight greatly reduced its importance by showing that, the will apart, by the mere operation of the English law, the poet's widow was entitled to *dower*, and thus amply provided for. There is thus (though the query of why *second*-best, if a bed at all was to be left her, may perhaps have a certain pertinence) no very firm basis of proof for the domestic unhappiness of Shakspeare. Still, if anything in his life is certain, it is this, that, spending great part of his time in London, the poet did not find it essential to his felicity there to have the society of his wife; as probably she, on the other hand, though her husband had gone to the metropolis, was content to abide in Stratford, since it seemed to him the desirable arrangement. It is fair, we think, to infer from this that the affection subsisting between the two was a little on the hither side of enthusiasm.

To discourse here at this date of the genius of S. would be only to promulgate platitudes. The lofty eulogy of Dryden—'He was the man who, of all modern and perhaps ancient poets, had the largest and most comprehensive soul'—has since been generally acquiesced in. As dramatist, he is admittedly in the world without a peer; as poet (abstracting the differental forms), there are but one or two names in literature even to be named beside his; and dismissing his claims in either kind, we have in his works such a treasury of gnomic wisdom on all matters of human concernment as no other writer has ever bequeathed to the world. If we add, that this greatest of writers is one of the most unequal—that his works contain more than might be wished of what, as the product of such a mind, we need not scruple to call rubbish—and that nearly every vice in writing might be illustrated from them almost at will, we say simply what is patent to every reader not blinded by the stupid and mindless idolatry which too often of late in many quarters has displaced a rational admiration.

The only works of S. certainly published under his own hand were the two poems *Venus and Adonis* and *The Rape of Lucrece*, which appeared in 1593—1594 respectively. As was naturally to be looked for in the case of pieces on the stage so popular, certain of his dramas found their way from time to time into print, but no authoritative edition of any of them was issued during his lifetime. The first collected edition of his dramas was issued in 1623, by Heminge and Condell, his friends and co-proprietors in the Blackfriars and Globe theaters. A second edition followed in 1632; a third, in 1664; and a fourth in 1685.

In 1709, appeared the edition of Rowe, with a prefatory sketch of the poet's life. Of the 'Shakspearian literature' which followed, and the various re-issues of the dramas, with such masses of critical commentary and emendation as no other writer has ever perhaps been made the subject of, it would be hopeless to attempt an account. It must suffice to mention as successive editors Pope, Theobald, Sir Thomas Hanmer, Warburton, Capell, Stevens, Malone, and Dr. Johnson, whose elaborate introductory essay—whatever may be thought of the insolence of much of his criticism of the plays in detail—is perhaps, on the whole, as an estimate of the genius of the poet, as satisfactory as any that has since been writ-

ten. Down to our own time, there has been no remission of activity in this field of literary labor. More recently, the intelligent industry of Mr. Charles Knight specially deserves mention; and along with his may be given the names of Mr. Dyce, Mr. John Payne Collier, and Mr. Singer—all of whom have put forth elaborate and valuable editions of the dramas. An important edition was issued from Cambridge in 1863—1866, under the superintendence of two gentlemen of unquestioned scholarly competence, W. G. Clark and W. Aldis Wright.

In Germany, S. has long been thoroughly naturalized; and the German enthusiasm in regard of him is, if possible, even greater than our own. It was the celebrated Lessing who first decisively introduced him to notice in a series of essays, exhibiting the immeasurable superiority of his art to that of the pseudo-classical models of the French stage. Since his time, many of the most gifted of his countrymen have devoted themselves to the work of Shakspearian criticism and elucidation. From Goethe we have some exquisite fragments, most notably the criticism of *Hamlet*, occurring in his *Wilhelm Meister;* and after his, the names of Tieck, A. W. Schlegel (whose *Lectures*, of date 1809—1811, almost constitute an era in this special department of literature), Franz Horn, and Gervinus (an English translation of whose elaborate Commentaries has been published), occur as the most illustrious in connection with the present topic.

By Tieck and Schlegel together, the work of translation was undertaken; and the result of their joint labors, which takes rank as the standard German S., ranks also, in the opinion of competent judges, as a consummate and almost *unique* specimen of excellence in the translator's art. It has not unfrequently been alleged that, till the Germans made the discovery for them, the English people knew nothing of the greatness of Shakspeare. This is on the face of it ridiculous. The single sentence we have cited from Dryden, and the practical acceptance of it implied in the unexampled attention and industry which never ceased to be directed to the subject, sufficiently of themselves confute so idle a notion. What the Germans really did (and along with their services in the matter, must be included those of our countryman Coleridge, whose impulse and point of view, at least, if not something considerably more, were derived from German sources) was somewhat to methodize and enlighten for us an admiration never deficient, but always, like Jonson's regard for the memory of his friend, 'only on this side idolatry.' The old notion of S. was that of a genius in power and plentitude unrivalled, but licentious in its modes of operation, and more or less chaotic in its results; 'wild above rule or *art*, enormous bliss.' The new German criticism exhibited in the chaos the orderly outlines of a world; co-ordinated the confusion under rules till then unsuspected, and showed in what before had seemed irregular exercise of power admitted to be magnificent, obedience not less magnificent to a law of artistic evolution. It made calculable, in a word, the orbit of a luminary which had somewhat uncomfortably seemed to be sweeping at random through space. But the English people did not need it to *reveal* the luminary to them; throughout and from the first, they had seen and devoutly worshiped it. Also, to a great extent, it is due to the German enthusiasm of exposition, that over the whole continent, and wherever literature is intelligently studied—some little lingering, dying remnant of French prejudice except—the poet *par excellence* of England is now finally enthroned as the poet also *par excellence* of our whole modern world. The expositors and critics of S. at home and abroad are innumerable; amongst recent English writers are Dowden, Furnivall, and Swinburne.

SHALE, or SLATE-CLAY, an indurated clay, which often forms beds in the coal measures. It is chiefly composed of silica and alumina, in variable proportions, but also frequently contains a considerable amount of carbonate of lime and of oxide of iron. It is of a gray or grayish-black color, or brownish-red when containing much iron. Its structure is more or less slaty. It is soft, and easily reduced to powder. It is used for making slate-pencils. When free from lime and iron, it is reduced to powder, and used for making fire-bricks, for which it affords an excellent material. S. very often contains a notable quantity of bitumen, and when this is so much the case that the mineral has a shining resinous streak, and crackles and blazes in the fire, emitting a black smoke and a bituminous odor, it is known as *Bituminous Shale*. This variety sometimes passes on the one hand into common S., and on the other into coal. Impressions of ferns and other plants are very frequently found in shale.

Slate, Schist, and Shale are names employed to denote those kinds of rock which are laminated or fissile—that is, which possess a structure readily splitting into thin layers. Shale and schist are also synonymous, although the latter should be restricted to rocks with their layers irregular or foliated. True slate differs from them in not having its lamination produced by bedding. See SLATE. Nevertheless, all three names are often applied to the same substance.

Shale varies much in its composition. Clay, sand, lime, bitumen, and other bodies, either singly or any mixture of them, are included under the name, if they form rocks which split into layers in the direction of their bedding; clay, however, being an ingredient in most shales. Strange as it may seem, the line between even coal and some kinds of shale is not well defined; and in the case of the Torbanehill mineral, found near Bathgate, the question by which of the two names it should be called, led to a lengthened and costly litigation.

The importance of certain decomposing shales through which sulphuret of iron is disseminated, for the manufacture of alum has been long known, and the quantity raised for that purpose from the carboniferous beds of Lancashire and Lanarkshire and the lias beds of Yorkshire is very considerable, yielding about 16,000 tons of manufactured alum annually. Shales of a similar kind are worked in France, Germany, and North America.

Bituminous shales—that is, shales more or less less rich in carbon and hydrogen—form another class of these bodies which have, in recent years, attracted much notice as sources of oil for illuminating purposes. It is now more than thirty years since a Frenchman, named Du Buisson, introduced a method of distilling certain bituminous shales in France, at a comparatively low temperature, so as to obtain burning oil and other products. The process was afterwards tried in England, being used for a time in distilling a Dorsetshire bituminous shale, sometimes called 'Kimmeridge coal.' From this mineral, a burning oil, a lubricating oil, and a naphtha for dissolving caoutchouc, were obtained. But neither in France nor in England did the attempt to make a profitable manufacture succeed: in the former country, the poverty of the shales was the chief drawback; in the latter, the disagreeable smell of the oil, which could not be effectually removed, prevented it from obtaining favor in the market.

On account of these failures, the process fell into abeyance, until it was revived again by the success of the well-known patent of Mr. James Young (see NAPHTHA), secured in 1850 for the production of paraffin and paraffin oil from coal. With the exception of the solid paraffin, which Mr. Young was the first to obtain on the large scale, and the employment of coal instead of shale, the processes of Du Buisson and Young are essentially the same. This process has created a new and rapidly-increasing branch of industry, paraffin oil and paraffin being economically obtained by it from either coal or shale of certain kinds. Those who have paid any attention to the various beds of minerals which go to form what is geologically called the Coal Measures, are aware that it is only the seams of coal, ironstone, fire-clay, sandstone, and limestone, which until very lately have been looked upon as of any industrial importance. Interstratified between these and the other minerals of the series, are numerous beds of carbonaceous or bituminous shale, until recently considered useless. Many of these shales were found upon trial to yield from 30 to 50 gallons of crude oil per ton; and works—several of them of great size—have accordingly been started in many places over the entire area of the coal formation in Scotland, and also at various localities in England and Wales, for the manufacture of mineral oil, paraffin, &c., from this material.

Owing partly to the comparative cheapness of shale, and partly also to the fact that these products are obtained from it in a state more easily purified than when they are got from coal, the use of the latter as a source of them is now almost entirely given up. In Scotland, where the manufacture of paraffin oil is chiefly carried on, the shales used are called 'oil shales,' and it is estimated that there are now 800,000 tons of this material annually distilled. Such a quantity yields the following products:

Crude oil	25,000 gallons.
Paraffin	5,800 tons.
Lubricating oil	9,800 "
Sulphate of Ammonia	2,350 "

In the refining process, the crude oil is reduced to about one-half of its bulk before it is fit for burning. Besides the above, there is also a considerable quantity of 'coal gas,' unavoidably produced, and partly wasted. But for the distance of the oil-works, this would be consumed in some of the larger Scottish towns. Shales found in the Lias and some other formations, likewise yield mineral oil.

SHALLOO'N, a light worsted cloth, said to have been first made at Chalons in France, and to have derived its now corrupted name from that place.

SHA'LLOP (Fr. *chaloupe*), a large, open, old-fashioned boat, carrying two masts, rigged as in a schooner. Its principal use was in the fisheries, but it has now nearly given place to luggers and yawls.

SHA'LLOT (*Allium Ascalonicum*), a species of *Allium* (q. v.), a native of the East, introduced into Europe by the Crusaders—from Ascalon, it is said—and much cultivated for its bulbs, which are used like those of the onion, and sometimes for its leaves, which are used like those of the chive. The leaves grow in

tufts like those of the chive, but are larger. The S. is generally propagated by the cloves, which are planted just beneath the surface of the ground, or only partially beneath it, in spring, and the crop is ready for gathering in July or August. The flavor resembles that of garlic, but is much milder. In the vineyards of Italy the S. is naturalized.

SHA'MANISM is the ancient religion of the Tartar, and some of the other Asiatic, tribes. It is a belief in sorcery, and a propitiation of evil demons by sacrifices and frantic gestures. The following account of it is extracted from the *Asiatic Journal*. The priests are men or women, married or single. The character is acquired by pretending that the soul of a deceased priest has appeared to the individual in a dream, appointing him or her his successor. If the priests are in function, they wear a long robe of elk-skin, hung with small and large brass and iron bells; moreover, they carry staves carved at the top into the shape of horses' heads, also hung with bells; and with the assistance of these staves, they leap to an extraordinary height. The followers of the Shaman religion have neither altars nor idols, but perform their sacrifices in a hut raised on an open space in a forest or on a hill. Nor are there fixed periods for the performance of their ceremonies; births, marriages, and sickness, uncommon appearances in the atmosphere, or public calamities, are generally the occasions which call for them. The animal to be sacrificed is generally fixed upon by the Shaman or the donor; and after the persons uniting in the ceremony have assembled, the Shaman enters the hut, chanting certain words, sprinkles on all the sides of the hut, and over the fire, spirits and milk, and then orders the animal to be killed, which is done by its heart being torn out. The skin of the victim is then stripped off, and its flesh with the exception of a few pieces which are thrown into the fire, is consumed by the persons assembled. See also LAMAISM.

SHAMMAI (not, as has often been done, to be confounded with Sammeas), an eminent doctor of the Jewish law at the time of Herod, head of a most important school, and supreme judge of the Sanhedrim (Ab-Beth-Din) during the presidency of Hillel (q. v.), along with whom he is, indeed, generally mentioned, and of whom he was, as it were, the very counterpart. Very little is known of the history of his life. He most probably was born in Palestine, and most energetically participated in all the political and religious complications of the country. There was a harshness and rigidity in his character, which constrasts most strikingly with Hillel's proverbial patience. His religious views were painfully strict, and he even tried to extend the rigor which he imposed upon himself, to the youngest children; but the zealotism with which later times have charged him, is not his, but his school's, 'the House of Shammai,' as it was called. This seems, under the adverse circumstances of the commonwealth—sedition within, and the approaching enemy without—to have developed a fanatical zeal that at times surpassed all bounds, and chiefly tended to foster that exceptional exclusiveness which proved both the bane and the saving of Judaism. The discussions of the two rival schools, of which that of S. preponderated long after the master's death, turned exclusively upon points of positive law. There is only one curious metaphysical debate recorded, viz., whether, as one school held, 'it was better for man to have been created or not;' or, as the other asserted, 'it would have been better if he never had been created.' Finally, they both agreed in the latter axiom, but with the addition—'but since he is now in this world, let him be careful in his actions.' We need hardly point to the strange light which this discussion and final decision throw upon the times of unequalled national misery that begot them.

SHA'MMOY. See LEATHER.

SHAMO, or GOBI, the Chinese and Mongol names respectively for a wide region of steppe and desert in the eastern part of Central Asia. It extends from the Thian-Shan Mountains to the Kuen-Lun and Nan-Shan Mountains, bordering on Eastern Turkestan to the west, and occupying great part of the area between 40° and 45° N. lat., and 90° to 118° E. long. The 'desert' is by no means sterile throughout. On the north and on the south is a wide belt of firm steppe, consisting for the most part of vast green levels covered with abundance of pasture, but broken by numerous ridges of hills. Between these two belts, each at a height of from 4500 to 5500 feet above the sea, lies a depressed tract, not more than 2500 to 3000 feet above sea-level, and varying in breadth from 230 to 460 miles. This alone is properly called S., or 'sea of sand;' it is a perfect wilderness of sand and stones, and is probably the bed of an ancient sea. The salt sand of which its soil is mainly composed produces nothing but a few scrubby plants. The fauna of the S., even in the wider sense, is limited, including little save hamsters, dziggetais, a few wild sheep, and antelopes. There are no fixed habitations even in the steppe country; the inhabitants, chiefly Mongols, are all nomads. Yet in various places there are traces of ancient cities buried in the shifting sand (see *Ocean Highways* for 1873). The winter here is intensely cold and stormy, and the summer excessively hot. Yet the wandering hordes of Mongols have no difficulty in keeping large herds, which find plenty of rich pasture on the steppes, and even in winter contrive to pick sufficient food from beneath the snow. From want of wood, the nomadic tribes have to use dried dung as fuel. Little is known of the S., save in the neighborhood of the main tracks across it, of which the chief is from Maimatchin to Pekin.

SHA'MROCK, a national emblem of Ireland, a leaf with three leaflets, or plant having such leaves, sometimes supposed to be the Wood Sorrel, but more generally believed to be some species of Clover, or perhaps some common plant of some of the nearly allied genera, as the Bird's Foot Trefoil, or the Black Medick. It is not improbable that the name has a sort of general reference to plants with trifoliolate leaves, and that a more exact determination of the species may be as difficult as the attainment of botanical accuracy in regard to the emblematic thistle of Scotland.

The small-leaved clover (*Trifolium repens*) has had a superstitious respect attached to it from early times. According to the elder Pliny, no serpent will touch it. It is said to have been first assumed as the badge of Ireland, from the circumstance that St. Patrick made use of it to illustrate the doctrine of the Trinity. See TREFOIL.

SHAMYL, or SCHAMYL (Eng. 'Samuel'), the celebrated leader of the independent tribes in the Caucasus, was born at Aul-Himry, in Northern Daghestan, and belonged to a wealthy Lesghian family of rank. He was one of the zealous disciples of Kasi-Mollah, the great apostle of Muridism, and ably seconded his endeavors to compose the numerous feuds of the various Caucasian tribes, and unite them in a bond of antagonism to their common enemy, the heretical Russians. He was one of the foremost in the defence of Himry against the Russians, October 30, 1832, and after the fall of his chief, Kasi-Mollah, and most of his adherents, fought his way alone and severely wounded through the besiegers' ranks.

After the assassination of Hamzad-Bey, the successor of Kasi-Mollah, in the end of 1834, S. was unanimously elected 'imaum,' and being absolute temporal and spiritual chief of the tribes who ackowledged his authority, he made numerous changes in the religious creed and political administration, for the purpose of more fully concentrating in himself the whole power. These changes were certainly the chief cause of the great successes which subsequently attended the mountaineers, but it is none the less certain that they produced that sudden collapse of the spirit of independence which took place when the great leader was removed. S.'s change of military tactics, from open warfare to surprises, ambuscades, &c., brought numerous and sometimes great successes to the arms of the mountaineers. General Ivelitch was severely defeated in 1837, the worst reverse the Russians had yet sustained, and his coadjutor Hafi was forced to make a disastrous retreat. They succeeded, however (1839), in hemming S. into Akulgo, in Daghestan, took the fortress by storm, and put every one of the defenders to the sword, in order to be quite certain that S. should not escape. How he did so is not known, his own followers and the Russians believed him to be dead, when, to the joy of the one and the bitter confusion of the other, he suddenly appeared, preaching with more vigor than ever the 'holy war against the heretics.' In 1843, he conquered all Avares, besieged Mozdok, foiled the Russians in their subsequent campaign, and gained over to his side the Caucasian tribes which had hitherto favored Russia. This accession of power rendered necessary some change in the government; a civil and a criminal code were promulgated, a regular system of taxation established, and Dargo was made the capital of this Caucasian monarchy, the population of which now (1844) exceeded 1,000,000. But the Russians, under Prince Woronzoff, having changed their tactics, assailed the country on various points at the same time, and the advance gained was secured by chains of forts.

The fortune of war, however, steadily alternated till 1852, when Bariatinsky compelled S. to confine himself to the defensive, and deprived him of his victorious prestige. Some of the tribes now returned under Russian authority, and S. (probably owing to his diminished power and resources) was unable to take advantage of the diversion in his favor afforded by the Crimean War; after the conclusion of which the Russians resumed their attacks with more energy, opened a road over the mountains, thus cutting off one portion of the patriots, and compelling their submission. The following year was still more disastrous; 100 villages were destroyed, the inhabitants transplanted to Russian districts, and S. himself defeated, August 11. On April 12, 1859, his chief stronghold Weden was taken after a seven weeks' siege, and his authority, except over the small band of followers who still devotedly adhered to him, was wholly destroyed. For several months he was a mere guerilla chief, hunted from fastness to fastness, till at last (September 6, 1859) he was surprised on the plateau of Gounib, and after a desperate resistance, in which his 400 followers were reduced to 47, he was captured. His wives

and treasure were spared to him, and he was sent to St. Petersburg, where he experienced a generous reception from the czar. A few days afterwards, he was assigned a residence at Kaluga, with a pension of 10,000 roubles. Thence he went, in 1870, to Mecca, remaining a parole prisoner of the Russian government; and died at Medina in March 1871, in the 74th year of his age.

SHANGHAI', the most important maritime city of China, situated on the left bank of the Hwangpoo or Woosung River, 12 miles from where it debouches into the southern portion of the mouth of the Yangtse-kiang, in lat. 31° 14′ N., and long. 121° 30′ E. Though it is now one of the first emporiums of commerce in the East, only a quarter of a century ago it was but a third-rate Chinese town. It is a *heen* or *district* city, having a wall 3 miles in circuit, through which 6 gates open into extensive suburbs. The low alluvial plain on which it is situated is of great extent, and intersected by innumerable creeks, which environ the walls, and permeate the city in various directions. It is a dirty, poorly-built town, the houses are brick, the streets are very narrow, and constantly crowded with people. Few of the buildings rise above the low walls of the city; the only conspicuous objects are the Roman Catholic cathedral, a massive edifice, and the lofty spire of the Baptist chapel. The temples present the same general appearance met with in all Chinese cities. Every city has its Chinghwang, or temple of the tutelary gods; that of S. is in a picturesque position on a rocky islet, surrounded by a serpentine sheet of water, which is crossed by zigzag bridges. A little further down the river stand the foreign settlements, English, French, and American. The whole of the mercantile *hongs* are built upon the English concession; while the French concession is mainly occupied by *go-downs*, wharves, and Chinese houses. There are no French merchants in Shanghai. The river in front of the Chinese town is thronged with junks, lashed side by side for a couple of miles. The reach in front of the foreign settlement was formerly crowded with sailing-vessels; but since the opening of the Suez Canal, the steamers of the P. and O. Steam Navigation Company and of private companies have largely taken their place.

Lower down are the ship-yards, machine-shops, and dry-docks, which foreign commerce has called into existence; and here the Chinese government has at work an arsenal where war-vessels of the largest tonnage are built and equipped. Under the arrangement by which the foreign custom-house dues are collected by foreigners, facilities have been created for the navigation of the Yangtse by stationing a light-ship, buoys, and signals, rendering safer the approach to this important mart. One or two lighthouses have also been recently erected, giving additional security to vessels entering and leaving the port. There are a chamber of commerce, reading-room, library, and literary institution—nothing being wanting to render the port of S. the metropolis of Eastern commerce. The municipal government of the foreign settlement is highly creditable to the mercantile traders. Several gentlemen are elected annually by the land-holders, for the purposes of local government—police, public improvements, and repairs requiring much management, and entailing much expense, the funds for which are obtained by taxation. S. is also the seat of various missions for converting the natives—the schools, dispensaries, and other benevolent objects meeting with generous support from foreign merchants. The products of S. itself are not of much value, but the city is a most important entrepot for goods passing between the north and south provinces of China, as well as for the imports and exports from and to foreign countries. It was in the possession of the Tae-ping rebels from 1853 to 1855, and the prosperity both of the native town and the foreign settlements was in peril for a time; but it enormously advanced after their expulsion —the English quarter in particular becoming a refuge for the Chinese from all parts of the province of Kiang-su, which the Tae-pings continued to desolate up to 1862. The trade of the port increased threefold between the years 1860 and 1863, owing to the large and increasing trade of the ports opened on the Yangtse. S. was connected with Tien-tsin by telegraph in 1881.

Between 1870 and 1880 the imports of foreign produce had a value of £12,000,000 to £14,000,000 (about half from Britain), and of native produce over £10,000,000; the exports of native produce, about £8,000,000. The articles of import and export are of a most miscellaneous description; the chief articles of import being opium, English cotton and woollen goods, and metals; and of exports, tea and silk. Great quantities of the opium imported into S. are re-exported to the other parts of China. The mercantile importance of S. has increased greatly through the opening of the Yangtse River to commerce. In 1876, the first railway in China was opened from S. to Kangwang, but it has since been bought up by the government and closed. The population is estimated at 250,000.

SHA'NNON, the largest of the rivers of Ireland, rises in the Cuilcagh Mountains, county of Cavan, and after a course of 230 miles, falls into the Atlantic Ocean between the headlands of Loop and Kerry Head. It is commonly divided into two portions, the Upper S. from its source to Limerick, and the Lower S. from Limerick to the sea, a distance of 56 miles. In its upper course it passes from its source in Cavan to Lough Allen in the county of Leitrim; thence through a difficult channel, where the navigation is in part transferred to a canal, to a small expansion called Corry Lough, and, with alternations of river and lake, to Lough Forbes, in the county of Longford, on leaving which the river for a time attains an average width of 250 yards as far as Lanesborough. Here it is again merged in a lake called Lough Ree, which stretches ten miles southwards to within two miles of Athlone. At this point great natural difficulties have been overcome, and the course of the river, by Shannon Harbor and Portumna, and through the picturesque Lough Derg to Killaloe, has been so deepened and improved that a regular passenger and goods traffic is maintained.

From Killaloe to Limerick the navigatian, owing to the rapid fall, is again in part transferred to a canal. On approaching Limerick the river divides into two branches, and on the island thus formed stands what is known as the Irish Town, in contradistinction to the English town, of Limerick. From the city, where an extensive and commodious range of quays has been built, to the sea, the S. is navigable to sea-going vessels; and though near the city very shallow at low water, the navigation for the last 40 miles is free at all times of the tide. The entrance between Kerry Head and Loop is seven miles across. About ten miles from the entrance the river narrows to about a mile and a half in width. At present, however, the outward navigation commences at Foynes, which is connected by railway with Limerick, and from which steam-boats daily ply to Kilrush, Tarbert, and the intermediate stations. Several rivers of considerable size fall into the S. during its course, as the Suck, the Brosna, the Fergus, the Maigue, and the Feale. The improvement of the S. was commenced under the Irish parliament. In 1837, the work was placed under a board of commissioners, by whom a sum of more than half a million was expended. It has since been transferred to the Board of Works or Local Government Board. The navigation is open from the head of Lough Allen to Limerick, a distance of 143 miles in a direct course, but by the addition of the Boyle branch of 9 miles, and the Strokestown branch of 6 miles, a total length of river and canal navigation of 158 miles is now open, over 129 miles of which large river-steamers freely ply. This important system of navigation, which occupies a position almost midway between the east and west coasts of Ireland, is connected with Dublin by means of the Grand and Royal Canals. The amount of tolls, &c. received in 1880—1881 was £3728; and expenditure in same year, £5324.

SHAN-SE' (West of the Hills), a province of North-Western China, is of rugged surface, and lies on the western limits of the plain. In the north are imperial hunting-grounds. It supplies the purest iron ore and the best coal in China, besides cinnabar, copper, marble, and other minerals.

SHAN STATES, a number of tributary states in Indo-China, lying between Munnipur on the west and Yun-nan on the east, and from the parallel of 24° N. lat., south to Bankok and Cambodia. Of these the northern states are tributary to Burmah (q. v.) and the southern to Siam (q. v.). A great portion of the mountainous region of these states is called the Laos Country. The Laos races are divided into two curiously distinct subdivisions. The northern race, beyond the northern frontier of Siam, are called *Black-bellies*, from the circumstance that they tattoo themselves with figures in ink, printed on their bodies, with sharp needle-like points; the southern race, mostly on and within the eastern frontier of Siam and tributary to that kingdom, are called *White-bellies*, and do not tattoo. Xieng Mai, the capital of Laos, stands on a wide plain on the right bank of the Meinam, 500 miles north of Bankok, and is said to contain 50,000 inhabitants. The number of Laocians included in Siam alone is estimated at 1,000,000. They are meek, gentle, unwarlike, and superstitious. Their chief employment is agriculture; and the principal crops raised by them are rice, maize, the sweet potatoe, calabashes, red pepper, melons, and other fruits. In religion they are Buddhists.

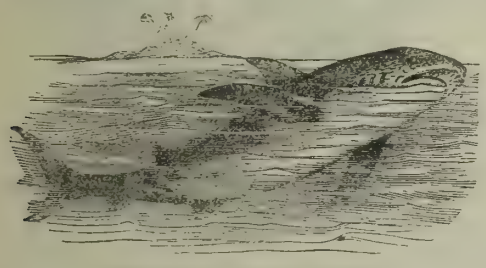
SHA'PINSHAY, one of the Orkney Islands, about 5 miles north-east of Kirkwall. It is 5 miles long and 4¼ miles in extreme breadth. The fine natural harbor of Elwick Bay on the south side is overlooked by a pleasant modern village. Pop. (1881) 974.

SHARI (i. e., *river*), the principal feeder of Lake Tsad or Tchad (q. v.).

SHARK (*Squalus*), a Linnean genus of cartilaginous fishes, now forming in Müller's system a suborder of *Plagiostomi* (q. v.), and divided into a number of families and many genera. The sharks have generally an elongated form, tapering gradually to the tail, and not much thickened in the middle. The muzzle projects over the mouth; the nostrils are situated on the under-side of the muzzle. The males have claspers. The gill-openings are lateral. There is no cartilage between the snout and the pectoral fin, as in

the rays. Some of the sharks are ovoviviparous; others lay eggs, generally a pair at a time, more being produced in succession. The eggs are large in comparison with those of osseous fishes, and are of a square or oblong form, with a tough horny coat, each corner prolonged into a tendril, the tendrils being apparently of use for their entanglement amongst sea-weeds. These eggs, or at least their empty cases, are very frequently cast up by the waves on the sea-beach, and are popularly known as *Sea Purses* or *Mermaid's Purses*. Near the head of the enclosed embryo there is a slit in the case through which water enters for respiration, and there is another at the opposite end, by which it is discharged. The young fish ruptures the case at the head, where it is weaker than at any other part, and on issuing from it, carries a yolk-bag attached to its belly for its nourishment until it is able to seek food. At this stage of its existence, its respiration is also aided by filaments projecting from the gills through the gill-openings, which are absorbed as it grows older. The teeth are generally large, sharp, and formed for cutting, with the edge often serrated; but in the genus *Cestracion* (q. v.) the teeth are pavement-like; and in some genera they are small and numerous. The Angel-fish (q. v.) is ranked among the sharks, but differs from the rest in its flattened form. Some of the smaller sharks are popularly known by the names Dogfish, Hound, Tope, &c. In the articles Cestracion, Dogfish, Fox Shark, Hammer-head, Por-beagle, and Tope, some of the S. tribe are noticed. It only remains here to notice a few of the more interesting of those which do not come under any of these heads.

The WHITE S. (*Carcharias vulgaris*) is the most dreaded of all the monsters of the deep. The family *Carcharidæ*, to which it belongs, have two dorsal fins, the first dorsal placed over the space between the pectoral and ventral fins; they have a nictitating membrane; and have no spout-holes. In the genus *Carcharias* the snout is flattened. The white S. attains a great size; one has been caught of 37 feet in length. The body is covered with a



White Shark (*Carcharias vulgaris*).

hard skin, and is grayish-brown above and whitish below. It is a very rare visitant of the British coasts, if indeed another species has not been mistaken for it; but is found in the Mediterranean, and is plentiful in the seas of many of the warmer parts of the world, often following ships to feed on any animal substance that may be thrown or may fall overboard, and often in its indiscriminate voracity swallowing things which are indigestible. A lady's work-box has been found in a S.'s stomach; and the papers of a slave-ship, which had been thrown overboard, in that of another. Human beings are not unfrequently its prey, and a large S. is not only capable of biting off the limb of a man, but of snapping the body in two, and has even been known to swallow a man entire. Its head is large, the mouth large and wide; furnished with a terrible apparatus of teeth, of which there are six rows in the upper jaw and four in the lower; the teeth are triangular, sometimes two inches in breadth, sharp-edged, and serrated; when not in use they are laid back in the mouth, nearly flat, but when the S. bites they are brought up—or at least those of the outer rows—by means of muscles with which each tooth is independently provided. The tail, as in all the sharks, is heterocercal, but its lobes are more nearly equal than in most of them.

The S. is often captured by sailors, by means of a great hook baited with a piece of meat, and attached to a chain, as the S.'s teeth readily bite through any rope. When the S. is hooked and hauled on board, great care is requisite to avoid danger both from the mouth and from the tail, the powerful action of the latter being generally interrupted by a sailor springing forward and cutting it above the fin with a hatchet. A curious method of catching the S. is practised in the South Sea Islands; a log of wood is set afloat with a strong rope attached to it, at the end of which is a noose, and the sharks gathering about it as if from curiosity, one of them may be expected soon to get its head into the noose, and is at last wearied out by the log. Formidable as the S. is, men have sometimes successfully braved it in its own element, watching its turning—as from the position of its mouth it must do—to seize its prey, and stabbing it in the belly.

The BLUE S. (*Carcharias glaucus*) is much smaller than the White S., seldom exceeding eight feet in length. It is also of a more slender form. The upper parts are of a blue color, the belly white. This species is common in the Mediterranean, and in the warmer parts of the Atlantic. It is not unfrequent on the south-western coasts of England in summer, apparently coming in pursuit of pilchards, and often doing great mischief to the nets and lines of fishermen, its sharp teeth biting through a net or line with the utmost ease.

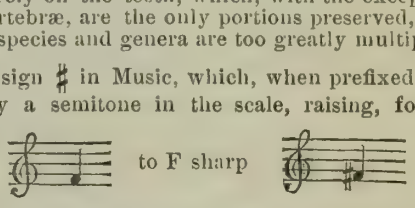
The BASKING S. (*Selache maxima*) belongs to the family *Lamnidæ*, having two dorsal fins, spout-holes, and no nictitating membrane. The snout of the Basking S. is short and blunt; the teeth are small, numerous, conical, and curved backwards. The skin is much rougher than in the White S. and Blue Shark. This species attains a great size, being sometimes 36 feet long, but it is not so thick in proportion as the White Shark. It is of a blackish-brown color, glossed with blue. It does not exhibit a ferocious character, and is supposed to feed on medusæ, crustaceans, and the like. It is often seen swimming slowly with its dorsal fin above the surface of the water, whence it has obtained the name of *Sail-fish*. It permits itself to be quite closely approached by a boat, but on being struck with a harpoon, it plunges suddenly down, and swims off with great rapidity, so that its capture is attended with danger. It is not uncommon on the northern and western coasts of Britain.

The GREENLAND S. (*Scymnus borealis*) is of the family *Scymnidæ*. It has large spout-holes, two dorsal fins, no anal fin, and no nictitating membrane. It inhabits the northern seas, and is rarely seen so far south as even the northern Scottish islands. It attains a length of 14 feet or more, is thick, and tapers suddenly at the tail; the fins very small; the teeth in both jaws so arranged as to diverge from a center. It bites and annoys whales, but feeds also on small fishes and crustaceans. When a whale has been killed, a S. will often come even whilst men are occupied in cutting off the blubber, and scoop out one great lump after another, and will return to its repast after having been severely wounded.

The rough skin of sharks is employed by joiners for polishing fine grained wood, and for covering the hilts of swords to make them firmer in the grasp—the flesh is coarse, but is sometimes eaten. The fins abound in gelatine, and are much used by the Chinese for making a rich gelatinous soup. Dried sharks' fins are a considerable article of import into China. The liver yields a large quantity of oil, which is now also, in some parts of the world, an article of commerce. For the sake of this oil a S. fishery is prosecuted on the coast of Ceylon.

Fossil Sharks make their first appearance in the Oolitic rocks from which eight species have been described. They become more numerous in the Cretaceous deposits, in which no less than 60 species have been found. In the Tertiary strata, their remains are still more abundant. But as the determination of fossil species depends entirely on the teeth, which, with the exception of the spines and vertebræ, are the only portions preserved, it is probable that the species and genera are too greatly multiplied.

SHARP, a sign ♯ in Music, which, when prefixed to a note, elevates it by a semitone in the scale, raising, for example,



When placed at the beginning of a piece of music, it denotes that all the notes on the line or space on which it is placed, and their octaves above and below, are to be played sharp. A double sharp × raises a note two semitones.

SHARP, JAMES, Archbishop of St. Andrews, was the son of William Sharp, sheriff-clerk of Banffshire, and was born in the castle of Banff, May 1618. Educated for the church at the University of Aberdeen, where he attained distinction as a student, and where he is said (on the authority of a tract, entitled *A True and Impartial Account of the Life of the Most Reverend Father in God, Dr. James Sharp, Archbishop of St. Andrews*, published in 1719) to have protested against the 'Solemn League and Covenant;' he afterwards visited England, and became acquainted with several eminent English divines, such as Hammond, Sanderson, and Taylor. Returning to Scotland, he was appointed a professor of philosophy at St. Andrews, through the influence of the Earl of Rothes, and soon after minister of the parish of Crail, an office which he held during the ascendency of Cromwell. In August 1651, when Monk was reducing Scotland to obedience, he was carried off, along with several other ministers, to England. S. quickly regained his liberty, and he possessed, for some years, the confidence of the more moderate party in the church. In 1656, he was chosen by them to plead their cause in London before the Protector, against the Rev. James Guthrie, a leader of the extreme section (the Protestors or Remonstrators), which he did with so much dexterity, that Cromwell is reported to have said: 'That gentleman, after the Scotch way, ought to be termed Sharp of that Ilk.' When the Restoration was on the eve of happening, S. was appointed by the moderate party to act as its

representative in the negotiations opened up with Monk and the king. This is the crucial period of his career, and on the view we take of his motives depends our whole estimate of his character. Was he sincere, or did he mean to betray the church to which he owed allegiance? Presbyterian writers are nearly unanimous in affirming his perfidy, although the evidence is doubtful.

Among the first things the Scottish parliament that met 1st January 1661 did, was to repeal or rescind every act passed since 1638, in consequence of which Episcopacy remained the Church of Scotland, as 'settled by law'—a dishonorable evasion of a promise made by Charles in a letter written to the Presbytery of Edinburgh in August 1660. Soon after, at a council held in Whitehall, S. was nominated Archbishop of St. Andrews, and having gone up to London, he was there formally consecrated by the Bishop of London and three other prelates. His government of the Scottish church was tyrannical and oppressive; and in consequence he became an object of hatred to most of his countrymen. When one Mitchell, a conventicle preacher, fired a pistol at him in the streets of Edinburgh, the populace allowed the intending assassin to walk quietly off, without making a single effort to arrest him. Finally, S. was assassinated on Magus Moor, near St. Andrews, 3d May 1679, by a band of fanatical Convenanters. In defence of S., the utmost that can be said is, that he was simply an ambitious ecclesiastic (of plausible and courtly manners), who had no belief in the 'divine right' of Presbytery, and who thought that if England were resolved to remain Episcopalian, it would be very much better if Scotland were to adopt the same form of church-government, and that if there must be an Archbishop of St. Andrews, there was no reason why he should not be the person. This theory is certainly a more sober one than the usual melodramatic Covenanting view, which makes him out to be 'a conscious villain,' who persecuted his old friends the more fiercely that he knew they were in the *right* and he in the *wrong*.

SHA'RPSHOOTERS, an old term applied in the army to riflemen. It is now appropriated to naval use, to the men stationed in the top to annoy those on the deck of an enemy's vessel.

SHASTRA or SHASTER, but more correctly written S'ASTRA (from the Sanscrit *s'âs*, to teach), means literally a book; but the term is especially applied to the *authoritative*, religious and legal, books of the Hindus. See SANSCRIT LITERATURE.

SHAT-EL-ARAB. See EUPHRATES.

SHAVE-GRASS. See EQUISETUM.

SHAWL MANUFACTURE. Perhaps no garment is of higher antiquity than the shawl; indeed, its simplicity of form would lead us to infer that it was the earliest in use. But of its manufacture we have no distinct account until the reign of the Emperor Jelal-ed-din-Mohammed Akbar, in 1556, when the celebrated Cashmere shawls were amongst the most important manufactures of the world, and were thought worthy to be minutely described in the *Ayin-i-Akbari*, or the 'Institutes of the Emperor.' In that work, four distinct classes of shawls, all of goat's wool, are described. The 1st were of remarkable lightness and softness, and were usually self-colored, and made of the wool undyed; the 2d were woven of wool in the natural colors—viz., white, black, and gray—these were probably arranged so as to form a plaid pattern similar to the shepherd's plaid of Scotland, which is of oriental origin; the 3d were called *gold-leaved*, probably from being embroidered with that material; and the 4th were long shawl-pieces large enough to enwrap the whole body. So carefully was this manufacture fostered, that it received the chief attention of the emperor, and every shawl manufactured was carefully described and registered, and the number of manufacturers was so great that in Lahore alone it is stated that there were upwards of 1000. The manufacture, in later times, passed through many vicissitudes, and during last century, it declined greatly; but in 1809, it had again risen, and there were then about 16,000 looms at work. From 2000 to 3000 of these beautiful fabrics are annually imported into Great Britain; but the admirable imitations now produced by our Paisley manufacturers, and by the French, are exerting great influence over the trade. The true Cashmere shawls are woven in many pieces, and joined together with great artistic skill; those of Britain and France are, however, woven in one piece, the loom being worked by hand, and of course furnished with a Jacquard machine for the production of the pattern. Besides the Cashmere shawls and their European imitations, there is an infinite variety of shawls made of various materials—as silk plain, embroidered, and in the form of crape; thread, cotton, and silk lace; and wool in a great variety of styles.

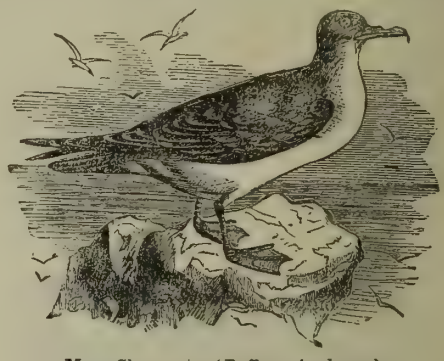
SHEA. See BASSIA.

SHEA'RING-MACHINE, a machine used in the preparation of woven woollen fabrics. See WOOLLEN MANUFACTURES.

SHEARS of various kinds are amongst the implements used in gardening. They are scissors on a large scale, variously modified to suit their various purposes, such as pruning trees, hedges, box-edgings, the verges of grass plots, &c. They are often furnished with long wooden handles, and a spring is sometimes fixed between the handles. A kind used for removing small branches of fruit-trees has one blade made to slide along the other whilst they are brought together, so that it makes a cut as clean and smooth as that of a knife.

SHEAR-STEEL. See IRON.

SHEA'RWATER (*Puffinus*), a genus of *Procellaridæ* (see PETREL), differing from petrels in having the tip of the lower mandible curved downwards, and the nostrils opening separately and not by a common tube. The bill is as long as the head, or longer, the upper mandible compressed and curved at the point. The legs are of moderate length, the tarsi compressed, the hind-toe rudimentary. The wings are long and pointed. The shearwaters spend their lives mostly on the ocean, rarely visiting the shore except for the purpose of incubation.—The GREATER, WANDERING, or CINEREOUS S. (*P. cinereus* or *major*) is about 18 inches long, the upper parts blackish-brown; the throat, breast, and belly gray. Young birds are entirely brown, the upper parts darkest. This species is frequently seen on the south-western coasts of Britain, It is very abundant on those of Newfoundland. —The MANX S. (*P. Anglorum*) is much more common on the



Manx Shearwater (*Puffinus Anglorum*).

British coasts, and is found also in more northern regions. It is about 14 inches long, grayish-black, the neck mottled with gray, the throat and all the under parts white. It breeds on islets, in rabbit-burrows, or in crevices of the rocks.—There are several other species in warmer climates.—The name S. is sometimes also given to the Skimmers.

SHEATH-BILL (*Chionis*), a genus of birds of the family *Chionidæ*, placed by many naturalists among the *Grallæ*, but by others regarded as belonging to the *Gallinaceous* order, and ranked by Mr. Swainson among *Columbidæ*. The legs are stout and moderately long, the toes much resemble those of the common fowl, but the fore-toes are united at the base. The bill is thick and conical, and the base is covered by a horny sheath, which the bird has the power of raising and depressing. The WHITE S. (*C. alba*) inhabits the shores of Australia, New Zealand, and neighboring islands, and feeds on molluscs, crustaceans, and whatever animal substance is thrown up by the waves. It is about the size of a partridge.

SHEATHING is a protection for the wooden planking of the immersed portion of a ship from the attacks of the teredo and other worms, molluscs, and marine animals, which especially in hot climates, adhere to the bottom and eat into the timber, while they retard the vessel's progress. As early as the time of Trajan, sheets of lead were used as sheathing. Thin deal boards, about half an inch thick, were in more modern times nailed on and frequently changed; but about the commencement of the present century, plates of copper were introduced, which have been found most effectual, though expensive. The gradual oxidation of the copper by the action of the sea-water produces a sort of poison, which prevents any marine animal from adhering, and keeps a clean bottom. The copper, however, slowly wears away in this oxidation, and requires renewing after a few years. To prevent this loss various methods have been devised. Sir H. Davy applied what he called protectors, consisting of pieces of iron and zinc on different parts of the *copper;* the action of the water on the two metals produced a small galvanic current, which prevented the copper from oxidizing; but it became forthwith encased in barnacles and weeds. For ships stationary in harbor, as hulks, ships-in-ordinary, &c., this system of protection answers well; but it fails for sea-going vesseis, together with many other protecting mixtures which have been tried, from the fact that in proportion as the copper is saved from oxidation, by so much does it cease to repel the incrustations which always threaten it.

SHEAVE. See PULLEY.

SHE'BA. See SABÆANS.

SHEBOY'GAN, a town and port of Wisconsin, U. S., on the west bank of Lake Michigan, at the mouth of the Sheboygan River, 52 miles north of Milwaukee. It was settled in 1836, has a good harbor, with mills at Sheboygan Falls, 6 miles above, and a large trade in wheat and timber. Pop. (1870) 5310; (1880) 7314.

SHECHI'NAH (from *shachan*, to reside, rest), a word used in post-biblical times by the Jews, and adopted by early Christian writers: expressive of the presence of the Divine Majesty, in Heaven, among the people of Israel, or in the Sanctuary. It is first found used in the Chaldee versions (Targums) as a kind of periphrasis for the person of God, wherever it is mentioned in the Bible as corporeal: thus being a kind of spiritual interpretation of anthropomorphism. The S. is not supposed to have dwelt in the second temple, but it is to return with the Messiah. The particular place where the S. was supposed to dwell was the 'mercy-seat between the cherubim.' The cherubim or other angels were always more or less connected with the S. itself, as in the phrases 'the heavenly hosts,' 'hosts of saints,' &c., accompanying the Divine presence. The first mention of the word is found in the Targum Jerushalmi, Gen. iii. 24—'And he expelled Adam, and caused to reside the splendor of his Shechinah from the beginning at the east of the garden of Eden, above the two cherubim.' (Second recension: 'between the two cherubim.') Another characteristic instance of its use is found in the version of Onkelos, Deut. iii. 24—'Thou art God, Thy divine Shechinah is in Heaven above, and rules on earth below.'

SHEEP (*Ovis*), a genus of ruminant quadrupeds of the family *Capridæ*, so nearly allied to goats that the propriety of generic distinction is very doubtful. They differ from goats in having the outline of the face more or less arched and convex; the horns spiral, sometimes very large in the males—in domestication, however, often wanting in the females, and also in the males of some breeds; the chin destitute of a beard; a sac or pit between the toes of each foot, lined with hair, and secreting a fatty matter. It is supposed by some that all the wild sheep existing in different parts of the world are mere varieties of one species, but of this there is no sufficient proof, nor is there anything more than unsupported conjecture in any of the opinions advanced concerning the origin of the domestic sheep, such, for example, as that which refers it to the Moufflon (q. v.), or that which ascribes different domesticated breeds to different wild originals, as the Moufflon and the Argali (q. v.).

All the wild sheep known are natives either of mountainous regions or of dry and elevated table-lands. They are gregarious, a character which the domesticated sheep fully retains. They are generally seen in small flocks, and are not easily approached, taking refuge in flight, a sharp whistling sound, emitted by one of the rams, serving as an alarm to the whole flock; although they are very capable of making a vigorous defence when driven to close combat. A ram of the domestic species is, indeed, able to sustain a conflict with a bull, taking advantage of his far greater agility, and butting against his foe with his strongly armed forehead. A ram has been known to throw a bull on the ground at the first onset, and is always ready to defend himself and his companions against a dog. Many rams exhibit great pugnacity. Sheep differ from goats in their mode of fighting. Goats rear themselves on their hind-legs and throw themselves sideways on their adversary, to bring the points of their horns to bear. Sheep rush straight at each other, a mode which better suits the different style of armature of the head. Rams of the blackfaced variety are especially powerful with their heads, and often at the rutting season kill each other. Their naturally strong skull is considerably protected in battle by heavy arched horns. A thorough ram fight is a terrifying sight. The two warriors go backwards each some fifteen or twenty yards, and then meet each other with great violence, their heads cracking loudly, and their beam-ends rising in response to the collision of heads. Ewes of this breed fight also. Sheep without horns are not so pugnacious as the mountain breeds.

All the wild sheep have short wool, with an outer clothing of long and nearly straight hair. But even the long hair—at least on the Moufflon—has the peculiar character of wool, in that roughness of surface which gives it the property of *felting* (see HAIR and FELT). One effect of domestication in the common sheep has been to cause the disappearance of the outer long hair, and to produce instead an increase of the length and abundance of the wool, an object of great importance to the sheep-farmer. In neglected breeds of the common sheep, the two kinds of hair or wool are very apparent. In some tropical climates, the sheep loses its abundant fleece, and is covered with hair little longer than that of the ox.

Although not equal to goats in their adaptation to rocky steeps, and not endowed with such power of leaping from crag to crag, most breeds of sheep exhibit a strong disposition to seek their food in places where no animal not very agile and sure-footed could venture; and those of the domesticated breeds which retain much of their original wildness are thus adapted to situations in which otherwise the pasture would be of little value to man. Every one who has seen the lambs frisking on a Highland hill, in a fine evening, must have admired their nimble movements in places where a herd-boy could with difficulty scramble. In fine weather, sheep ascend the heights; and in cold and stormy weather, they repair to the lower grounds. In modern times it has been customary to remove the large flocks from mountainous regions to lower grounds to pass the winter; and in the fall of the year, shepherds have difficulty in preventing the animals from leaving the summer pastures too early if the weather is unfavorable. On the other hand, if fine spring weather sets in before the period of removal from the winter quarters, the flocks keep pressing towards the summering regions. Mountain sheep have favored spots whither they go regularly over-night, and the ewes generally have choice localities to which they go to lamb. They get much attached to certain pastures, and many of them have been known to return stealthily, in the course of a few days, to their native or appreciated pastures, though removed some hundreds of miles.

A very interesting species of the wild sheep is the ROCKY MOUNTAIN SHEEP, or BIG-HORN (*O. montana*), of North America. It is equal in size to the argali, which it much resembles also in

Rocky Mountain Sheep.

its general appearance, and in the size and curvature of its horns. The horns of the old rams attain so great a size, and are so much curved downwards and forwards, that they often effectually prevent the animal from feeding on level ground. The abode of this species is in the most craggy and inaccessible parts of the Rocky Mountains. The flesh is of the very finest quality. The wool is very fine, and fully an inch and a half long; it is completely concealed by long hairs. The general color is brown, paler on the lower parts; the old rams are almost white in spring. The AOUDAD (*O. tragelaphus*) is a native of the north of Africa, inhabiting chiefly the lofty parts of the Atlas Mountains. It is sometimes called the Bearded Argali, although it has no beard on the chin; but the throat, the chest, and the front of the forelegs are remarkably adorned with long shaggy hair. On other parts the hair is comparatively short, with an underclothing of short wool. The color is a uniform reddish-yellow. The tail is longer than in the other wild species, and is terminated by a kind of tuft of long hairs. The horns are not so large as in the other wild species. In size, the Aoudad exceeds the Moufflon, but is not equal to the Argali. The French call it *Moufflon a mouchettes*, or Ruffled Moufflon, from the long hair of its forelegs.

The COMMON SHEEP (*O. aries*) was probably the first animal domesticated by man. We are told in the book of Genesis that Abel was 'a keeper of sheep,' and that he brought an offering unto the Lord 'of the firstlings of his flock and of the fat thereof.' And from that time until the death of Christ, lambs continued to be the most frequent sacrificial offerings, both amongst the patriarchs and the Jews. The felting and weaving of wool were unquestionably among the earliest of the arts. The wool was probably at first pulled from the skin, a rude and even cruel practice, which it is said still subsists in some countries, and was not very long ago relinquished in the Orkney Islands. We read in Genesis xxxviii. of Judah shearing his sheep, and there is abundance of other evidence that the better mode of obtaining the fleece has been in use from remote antiquity. The leather made of the skin of the sheep is much employed in bookbinding, and for making gloves. In patriarchal times, the milk was much used, as it still is in some countries; it is richer than cow's milk, and the cheese made of it has a sharp taste and strong flavor, which, however, are greatly relished by some. In Britain the milk is now very little used. In some mountainous parts of India the sheep is even used as a beast of burden, carrying loads of from 35 to 40 pounds,

over rough tracks, and up steep crags, where almost no other animal could be employed.

Those who watch sheep carefully, or keep them as pets, find them by no means devoid of intelligence. They have, however, a stupid habit of following, without scruple, the leader of the flock; so that, when sheep are being driven across a narrow bridge, or where a fence separates the road from a precipice, if anything occur to deter them from proceeding in the proper path, and one break over the fence or parapet, more of the flock may be expected to follow, as has sometimes happened, to their utter destruction. Sheep very soon come to know the voice of the shepherd, and also the appearance as well as the bark of the shepherd's dog. Though they stand more in awe of the shepherd's voice or commands than of any other human being's, the dogs regularly moving amongst them fail to keep them in such subjection as strange ones do.

The 'rutting' is from September till the middle of December, according to the variety of sheep, and the system of feeding. White-faced modern breeds have the tups early among them, and the hill flocks are later. The period of gestation is from 20 to 21 weeks. Ewes occupying sown or low-ground pastures lamb in March, while those not so well provided for—the mountain sheep—do not drop their lambs usually till April. The ancient breeds generally have only one lamb in a season, but modern highly-fed varieties frequently have twins, occasionally triplets, but rarely more. Lambs intended to come early into the market are as often as possible dropped in January. Generally lambs are weaned in July and August. Weaning of breeding or store lambs, however, is a feature of modern sheep-farming; at one time it was not uncommon to see several generations persistently following the parent stem. The shearing season ranges from the 1st of May till the middle of July, according to the description of sheep, the nature of the feeding, &c. Autumn is the most common time for the 'dipping,' 'juicing,' or 'smearing' of the flocks, to kill vermin, prevent skin disease, and preserve and cultivate the wool crop.

The great object for which the ancient Britons possessed sheep before the Roman invasion was the production of wool. The demand for butcher-meat has now raised the value of mutton and lamb so much, that the farmer finds it profitable to devote much of his attention to supply the market with these articles; and those breeds of sheep are reckoned most valuable which are most suitable for this purpose, even although the quality of the wool is inferior. When there was no food for sheep but the natural pasture, the animals could not be fattened for the market except during summer, and not until they had attained an age of three, four, or five years; whereas much of the mutton now consumed is the flesh of sheep not more than two years old, fattening being aided by turnips, mangold, oil-cake, &c.

The young branches of heath, and in lower situations, the shoots of furze, often serve as food for sheep, when the supply of grass fails. Sheep delight in the short grass and peculiar herbage of hill pastures and bare downs; and the mutton produced in such pastures, and by the breeds most suitable to them, is of superior quality to that of the large fat sheep fed on richer soils. The latter are also more liable to many diseases, particularly where the ground is at all moist. Aromatic and bitter herbs are particularly relished by sheep.

The breeds of sheep are very numerous, and very different.—The BLACK-FACED SHEEP of the Highlands of Scotland and of the north of England is perhaps as near the original type as any existing breed. Both male and female have horns; those of the

Black-faced Ewe and Ram.

ram large, with two or more spiral twists, those of the ewe much smaller, and little twisted. The face and legs are not always black. Many are speckled, and some principally white. The Black-faced sheep is robust, very active and hardy; enduring the rigors of a severe winter when sheep of most of the breeds common in Britain would perish. It survives on little food, and shifts admirably for itself in a snow-storm. The small quantity, and even inferior quality of food with which a Black-faced sheep will tide over a snow-storm, is most surprising.

As an instance of the tenacity of life in Black-faced sheep, under certain circumstances, they have been known to be buried five weeks under a snow-wreath and come out alive. It has a bright, quick eye, with an expression very different from that softness which is seen in many of the breeds, preferred for lower grounds and better pastures. The wool is long and coarse, and the weight of the fleece from three pounds to four pounds; but the mutton is of the finest quality; and on this account, and its hardiness, this breed is preferred to any other in many mountainous districts and on rough elevated moors.—The WELSH SHEEP is much smaller than the Black-faced; both sexes horned; the color various; the mutton highly esteemed; the fleece seldom weighs two pounds.—A very little larger breed with big bushy tail, hornless, or with short and little twisted horns, has long existed in the Shetland and Orkney Islands; its wool affording the material for the manufacture of Shetland hose. The Shetland and Orkney sheep are very hardy, and in winter feed much on seaweed.—Smaller than either of these, and, indeed, remarkably diminutive, is the hornless BRETON SHEEP.—The FOREST SHEEP of England, so called from being pastured in the royal forests, has now in most places been supplanted by other breeds. They are still to be seen on the barren grounds between the British and Bristol Channels; and the mutton is in much request in the London market. The original Forest Sheep was generally small, with face and legs russet brown or gray, wild, restless, and difficult to fatten, but producing wool of fine quality. The DORSET SHEEP is one of the best of the old English upland breeds. Both sexes have small horns. The wool and mutton are of medium quality; but the ewes are remarkable for their fecundity, and the abundance of their milk; and this breeding is valued as affording a supply of early lamb for the London market.

The RYELAND SHEEP has long existed in Herefordshire and some neighboring counties of England. It is small, short-limbed, white, hornless; produces excellent mutton; and before the introduction of Merino wool, its wool was preferred to every other kind for the manufacture of the finest broadcloths.—The CHEVIOT SHEEP has existed from time immemorial on the Cheviot Hills, and is now very widely diffused over a considerable part of England and almost all parts of Scotland, being hardy and well adapted for high grounds, although it is inferior in hardiness to the Black-faced. Cheviots, however, rather excel the Black-faced both in size and in the value of the fleece; but require a richer pasture. Ewes are hornless, and the rams almost so. The general figure is longer than that of the Black-faced sheep. They are narrow in shape, with slender forequarters and long pricked ears. The color is white, the face and legs occasionally mottled with gray, but generally quite white. The fleece weighs from three to five pounds. Great attention has for many years been devoted to the improvement of this breed.—The LEICESTER SHEEP is another of the most valuable breeds. This breed, as it now exists, is a result of the skill and care of Mr. Bakewell, who, soon after the middle of last century, began to make experiments for the improvement of the old Leicester sheep—a large, coarse-boned sheep, not easily fattened, and with coarse long wool, of which, however, the fleece weighed from eight to ten pounds. The new Leicester sheep has wool moderately long, of better quality, the average weight of the fleece being about seven or eight pounds; and is easily rendered very fat. It is naturally very broad on the back, with finely arched ribs. The color is white. Both sexes are hornless. The Leicester sheep is now common in all but the mountainous parts of Britain, and other breeds have been improved by crossing with it, particularly various breeds of long-woolled sheep, which have long existed in different parts of England, as those of Lincolnshire, Romney Marsh, &c.

A famous long-woolled breed is that called the COTSWOLD or GLOUCESTER, the wool of which was in great esteem in the 14th and 15th centuries, bearing a higher price than any other wool. In 1464, Edward IV. sent a present of Cotswold rams to Henry of Castile; and in 1468 a similar present was sent to John of Aragon. The Cotswold breed, however, as it at present exists, has been modified by crossing with the Leicester, and produces shorter wool and better mutton than in former times.—The SOUTH DOWN SHEEP has recently been improved with the utmost care. The color is generally white, and the face and legs are generally dun, black, or speckled. Both sexes are hornless. The wool is short, very close, and curled. The South Down derives its origin and name from the chalky *downs* of the south of England; but is now met with throughout England and the south of Scotland. The Shropshire sheep are large, with thick wool something like the South Down. They are hornless, and black or dun in the face and legs. They come early to maturity, but are suited only for finer climates and good keep. The Oxford Down is a heavy, somewhat soft sheep, without horns, and capable of rapid and

great development under good treatment. It is not suited to very cold and exposed situations.

The ICELAND SHEEP is remarkable for very frequently having three, four, or five horns. They are good butchers' animals, being deep and thick in the carcase, though rather short in the quarter. The same peculiarity, or monstrosity, as it may be deemed, is exhibited by the sheep of some of the most northern parts of Russia.—The north of Africa possesses a breed of sheep with legs of great length, pendulous ears, and much arched face; the wool short and curled, except on the neck and shoulders, which have a kind of mane.—India has also a hornless breed, with pendulous ears, short tail, and very fine much curled wool.—The BROAD-TAILED or FAT-TAILED SHEEP is found in many parts of Asia, as in Syria, India, and China, also in Barbary, and is now very abundant in the colony of the Cape of Good Hope. It is rather of small size, with soft and short wool. Its chief characteristic is the enormous development of the tail, by the accumulation of a mass of fat on each side, so great that the tail has been known to weigh 70 or 80 pounds. The tail is highly esteemed as a delicacy, and to protect it from being injured by dragging on the ground, the shepherd sometimes attaches a board to it, or even a small carriage with wheels. The fat of the tail is often used instead of butter. It is less solid than other fat.—The FAT-RUMPED SHEEP of Southern Tartary has a similar accumulation of fat on the rump, falling down in two great masses behind, and often entirely concealing the short tail.—The ASTRAKHAN or BUCHARIAN SHEEP has the wool twisted in spiral curls, and of very fine quality. The Circassian sheep has a remarkably long tail, covered with fine long wool, which trails on the ground.—The WALLACHIAN SHEEP, common in Hungary, as well as in the country from which it derives its name, is distinguished by the magnitude of its horns, and their direction. They make one great spiral turn, and then generally rise up from the head to a great height, twisting round as they rise. The wool is soft, and is concealed by long hair.

SHEEP-LOUSE, or SHEEP-TICK, or (in Scotland) KAID (*Melophagus ovinus*), an insect of the family *Hippoboscidæ*, to which also the Forest Fly belongs, ranks in the order *Diptera*, although in this genus the wings are completely wanting. It lives among the wool of sheep, and particularly of lambs, sucking the blood of the animal, and is most abundant in the early part of summer. Where it fixes its head in the skin, a large round tumor is formed. Its body is very compressed and smooth, of a rusty color, the head and thorax small, the abdomen large. The female does not lay eggs, but, like the other *Hippoboscidæ*, hatches the egg and nourishes the larva within her own body, till it passes into the pupa state, when it is deposited, oval-shaped and shining, fastened to the wool of the sheep. Sheep-farmers use various washes or *dips* for the destruction of these creatures, many of which are arsenical, while in others carbolic acid is a chief ingredient. The sheep tick is not a tick proper, not being one of the *Ixodidæ* (see TICK.)

Sheep-louse (*Melophagus ovinus*):

a, natural size; *b*, magnified; *c*, the pupa, magnified.

SHEEP'S-HEAD (*Sargus ovis*), a fish of the family *Sparidæ*, plentiful in the latter part of summer on some parts of the coast of North America, and highly esteemed for the table. It sometimes attains a weight of 14 or 15 pounds. A very large fish is sometimes sold in the New York market for a price equal to four or five pounds sterling. The fishery is therefore of some importance. Nets are used, and many fish are often taken at a single haul, which are immediately packed in ice for the market. It is difficult to take the S. with a line, as its cutting teeth snap the line asunder. The genus *Sargus* has cutting front teeth, and round teeth in the back of the mouth. *S. Rondeletii* inhabits the Mediterranean, and has been esteemed for the table from ancient times. The *Sargi* feed on shell-fish and the smaller crustaceans, which they easily crush with their round teeth; partly also on sea-weeds.

SHEEP-STEALING, in England, is felony, and is punishable with penal servitude from three to fourteen years, or imprisonment for two years. In Scotland, it is a capital offence, though, for some time, it has never been punished capitally.

SHEERNE'SS, a seaport and naval arsenal in the county of Kent, stands on the north-west extremity of the Isle of Sheppey, at the confluence of the Thames and Medway, 11 miles east-north-east of Chatham. It consists of four divisions, Blue-Town, Mile-Town, Marine-Town, and Westminster, and of these the first is within the limits of the garrison. The dockyard, much extended and improved within recent years, is now one of the finest in Europe. It covers 60 acres, comprising wet and dry docks, immense storehouses, and official residences. The harbor is usually crowded with vessels of all descriptions. An extensive oyster-fishery is carried on in the vicinity, from which as many as 50,000 bushels of 'natives' have been sent to London in one season. At Garrison Point is the residence of the port-admiral, the telegraph, coast-guard station, and barracks. The chief trade is in supplying the requirements of the employees in the various government establishments, and in the export of corn seeds and oysters. The neighborhood was once thought to be very unhealthy, but of late years important sanitary works have been carried out, and there are now few towns the population of which enjoy better health. Since the provision of direct railway communication with all parts of England, the town is much visited during the summer on account of the excellent sea-bathing there, which is under the management of a local joint-stock company. The beach and cliffs are a favorite resort for ramblers. Pop. (1881) 13,941. S. was captured by the Dutch under De Ruyter in 1667, and here the mutiny of the Nore burst forth in 1798.

SHEERS. The elemental form of a pair of sheers consists in two spars fastened together near the top, with a pulley at the point of junction, and held by a rope, fastened to any convenient object, in such a position that the weight lifted hangs nearly between the spars. This forms an easily improvised crane. An apparatus of this kind, of great height and strength, is used for masting vessels. In the principal dockyards, there are tall permanent sheers, mounted either on the side of a masting dock or on a floating sheer-hulk.

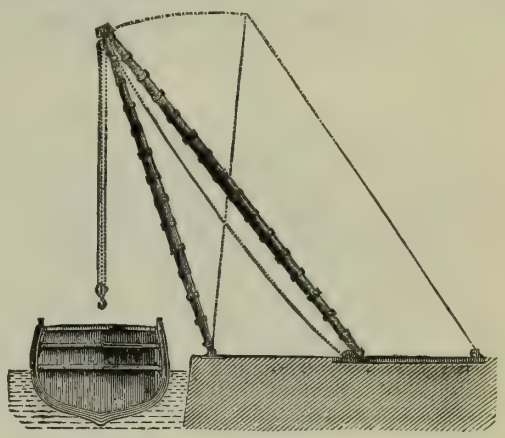


Diagram of 100-ton Sheers at Chatham Dockyard.

SHEET, on Shipboard, is the rope by which each of the lower corners of a square-sail, or the after-corner of a fore-and-aft sail, is held down, in order that the sail may be tightened to the wind.

SHEETING, a cloth made of flax or cotton, and used for bed-linen. It is chiefly made in Ireland in or near Belfast, and in Scotland. The term sheeting is also applied to the coarse hempen cloth used for making Tarpaulings (q. v.).

SHE'FFIELD, an important manufacturing town and parliamentary borough, in the West Riding of Yorkshire, and capital of an independent district, called Hallamshire (see SHIRE); it is picturesquely situated on several hills that slope towards the confluence of the rivers Sheaf and Don, 140 miles N.N.W. of London, with which it is connected by the Great Northern and Midland Railways, and 43 miles S.S.W. of York. The town, generally, is well built. It possesses many fine public buildings, such as the original parish church, supposed to have been erected in the reign of Henry I., 240 feet long by 130 feet broad; St. Mary's Catholic Church, surmounted by a tower 200 feet high; the town-hall, cutlers' hall, corn exchange; the new market-hall, or Norfolk Market, with a roof of glass and iron, erected by the Duke of Norfolk at a cost of about £40,000; music-hall, assembly rooms, theaters, &c.

There are extensive botanic gardens, and a fine cemetery about a mile from the town; many churches; numerous educational establishments, such as the Free Grammar School, the Collegiate School, the Wesley College, a Lancasterian and many national schools, free writing-schools, school of art, besides the Mark Firth College, opened in 1879. The Mechanics Institution dates from 1832. There are free and other public libraries, an Athenæum, and a Literary Society. The charitable institutions comprise an infirmary and several hospitals. As far back as the time of Chaucer, S. was noted for the manufacture of cutlery; and at the present day, an endless variety of articles in brass, iron, and steel is produced at the many manufactories with which the town abounds; such as knives of every description, silver and plated articles, Britannia-metal goods, coach-springs, spades, spindles, hammers, files, saws, boilers, stoves, grates, buttons, &c. In

March 1864, a new embankment, constructed for the Sheffield Water Company, at Bradfield, gave way, and let out a body of water 95 feet high from a reservoir 78 acres in extent. The destruction of life and property by this flood was unprecedented in England: 250 persons perished; mills, houses, and hamlets were swept away from their foundations, and, apart from the ruin of the Bradfield Dam, damage was done to private property to the extent of close upon £300,000. In 1866, trade outrages, in the form of 'rattening'—a local name for the stealing of tools and wheel-bands—and of unscrupulous treatment of the lives and limbs of non-union men, which had for more than twenty years been a disgrace to S., were brought to a prompt check by a Royal Commission, procured, among other influences, by the loyal outspokenness of the local press. Two fine churches have been recently erected—All Saints, a cruciform, early Second Pointed edifice, in 1867; and Sharrow Church, of the late First French Pointed period, in 1868. Since 1871, the introduction of the manufacture of armor-plates, railway-springs, tires, and rails has given a remarkable impetus to the growth of the town. The Albert Hall, erected in 1873, is a commodious building which seats 3000 people. S. has three public parks (one presented in 1878). Pop. (1871) 239,946; (1881) 284,403. The borough returns two members to parliament. Mary, Queen of Scots, was imprisoned in Sheffield Manor-house, about two miles from the town, for 12 or 14 years.

SHEIK (Arab, elder, aged person), a title of reverence, applied chiefly to a learned man, or a reputed saint, but also used sometimes as an ordinary title of respect, like the European Mr., Herr, &c. before the name. It is, however, only given to a Moslem. The Sheikh Al-Islam is the chief Mufti (q. v.) of Mohammedanism at Constantinople: a title supposed to have been first assumed by Mohammed II. at his conquest of Constantinople in 1453, when this place became the seat of his empire. The Sheikh of Mecca, by virtue of his supposed descent from the prophet, levies a kind of tribute on all the pilgrims to the Kaaba. The term is also applied to heads of Mohammedan monasteries (our abbot or prior), and to the higher order of religious preachers. Sheikh Al-Gebal (Ancient of the Mountain) is the name of the prince of the Assassins (q. v.), or those Ismaelites of Irak, who undertook to assassinate all those whom their chief would pronounce to be his enemies.

SHE'KEL (*siklos*, from *shakal*, to weigh), originally a certain standard weight in use among the ancient Hebrews, by which the value of metals, metal vessels, and other things was fixed. Gradually it became a normal piece of money, both in gold and silver, marked in some way or other as a coin, although not stamped. The gifts to the sanctuary, the fines, the taxes, the prices of merchandise, are all reckoned in the Old Testament by the shekel, not counted but weighed. Three different kinds of gold, silver, and copper shekels are mentioned: the common shekel, the shekel of the sanctuary (probably of double value), and the shekel of royal weight. Besides these, there was a half-shekel (*beka*), and a fourth-shekel. The sacred shekel was equal to 20 geras (beans), and 3000 sacred shekels made a talent. The gold shekel is reckoned approximatively to contain 161 Troy grains, the silver shekel 275. During the Babylonian exile, the Persian money (*dariks*) was used by the captives; nor do they seem to have afterwards used any but the coin of their foreign rulers. It was first under the Maccabæans that national money began to be struck, adorned with sacred emblems, and with inscriptions in the native language and characters. De Saulcy alone assumes, without much show of reason, Jewish coins to have existed from the time of Alexander the Great.

Simon, the 'prince and high-priest,' received, according to 1 Macc. xv. 16, the permission from Antiochus VII. to strike coin in 138 B.C. The emblems are sacred branches, sheaves, flowers, vases, &c., and the legend (in a peculiarly archaic ['Samaritan'] alphabet) contains the date, the name of the Jewish ruler, and the inscriptions 'Shekel of Israel,' 'Jerusalem the Holy,' 'Redemption of Israel.' The latest coins with Hebrew inscriptions date from the revolution of Bar Cochba under Hadrian. The value of the silver shekel is reckoned to be something over two shillings.

SHELBURNE, WILLIAM PETTY, Earl of, son of the first earl, and descendant of Sir W. Petty, founder of the science of political arithmetic, was born May 1737, and commenced his political career in 1761 by entering the House of Commons as member for Wycombe, but only sat for a few weeks, the death of his father having called him to the House of Lords. When Mr. G. Grenville succeeded Bute in 1763, S., whose talents had made him remarked, although only 26, was placed at the head of the Board of Trade. When Chatham formed his second administration in 1766, he made S. one of the Secretaries of State, although not yet thirty. Upon the fall of Lord North's Ministry in 1782, George III. sent for S., and proposed to him to form a government. He declined, not being the head of a party, and was sent by the king to the Marquis of Rockingham, with an offer of the Treasury, himself to be one of the Secretaries of State. According to Earl Russell, in his *Life of C. J. Fox*, it soon appeared that S. was not so much the colleague as the rival of Lord Rockingham, the chosen minister of the court, and the head of a separate party in the cabinet. Upon the death of Rockingham in 1782, the king sent at once for S., and offered him the Treasury, which he accepted without consulting his colleagues. Fox thereupon resigned, and S. introduced William Pitt, then only 23, into office as his Chancellor of the Exchequer.

S.'s ministry, on the occasion of the king's announcement of his determination to concede the independence of the American colonies, found itself outvoted by the coalition between Fox and Lord North. He resigned, and the coalition ministry took his place, but soon broke up. The nation expected that the king on this event would have sent for S., but William Pitt received the splendid prize, and S. was consoled by the coronet of a marquis (of Lansdowne). During the later years of his life, his health was delicate, and he withdrew from public life; but he came forward as a strong supporter of the union with Ireland. He indulged his tastes in the adornment of Lansdowne House. Here he collected a splendid gallery of ancient and modern pictures, together with a library of 10,000 volumes, comprising the largest collection of pamphlets and memoirs on English history and politics possessed by any man of his time, as well as a series of MSS., which were sold to the British Museum for £5000. He was a discerning patron of genius. It was while he resided in Lansdowne House as the librarian and friend of S. that Priestly made the discovery of oxygen. Jeremy Bentham was one of his most intimate friends. S. was the patron and friend of Sir S. Romilly, and twice offered him a seat in parliament. He was also on terms of intimacy with Mirabeau, Dumont, and other foreigners of literary and political distinction. He died in May 1805. See *Life of S.*, by Lord Edmond Fitzmaurice (London, 1875–6).

SHE'LIF, the chief river of Algeria (q. v.).

SHELL. This term is employed to designate the hard outer coverings of a large number of invertebrate animals. Shells are met with in the *Echinodermata*, in the great majority of the *Mollusca* (excluding the Molluscoids), in a few of the *Annelida* as Serpula, Spirorbis, &c., in the *Cirropoda*, and in the *Crustacea*. The forms of the different varieties of shells are sufficiently noticed in the articles on the classes of animals to which they respectively belong; and we shall confine our remarks to the intimate structure of shell, which, until the publications of Carpenter, Rainey, and others, during the last quarter of a century, was altogether misunderstood. The doctrine formerly held, and still maintained in many popular handbooks of conchology, was, that shell is not only extravascular (or devoid of vessels), but completely inorganic, being composed of an exudation of calcareous particles (chiefly carbonate of lime) cemented together by a kind of animal glue. It is now known that shell always possesses a more or less distinct organic structure, which in some cases resembles that of the *epidermis* of the higher animals, while in others it approximates to that of the *derma*, or true skin. The nature of the organic structure is so different in the Echinodermata, Mollusca, and Crustacea, that a separate description is required for each, and as Dr. Carpenter remarks: 'Even in the subordinate divisions of these groups, very characteristic diversities are frequently observable, so that, as in the case of the teeth, it is often possible to determine the family, sometimes the genus, and occasionally even the species, from the inspection of a minute fragment of a shell, as well fossil as recent.'

In the *Echinodermata*, the elementary structure of the skeleton exhibits the appearance of a net-work composed of calcareous and animal matter intimately united. The diameter of these

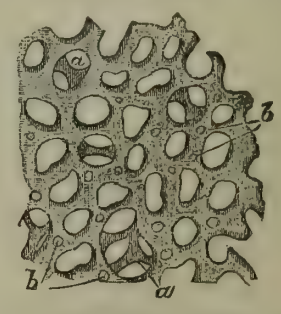

Fig. 1.—Thin Lamina of Shell of Echinus, showing its Areolar Structure:
a, *a*, portions of subjacent layer; *b*, *b*, fractured bases of columns connecting the superposed laminæ. Magnified 164 diameters.

apertures or meshes of network varies to a certain degree in different parts of the same shell, the openings being larger in the inner than the outer layers, the extremes being $\frac{1}{160}$th and $\frac{1}{1360}$th

of an inch. The entire shell is made up of an immense number of such plates, which lie parallel to one another, separated by minute vertical pillars.

In the *Mollusca*, the shell is formed upon the surface of the mantle, which corresponds to the true skin of other animals. Hence it must be regarded as epidermic. It consists of cells consolidated by a deposit of calcareous salts in their interior, but, as

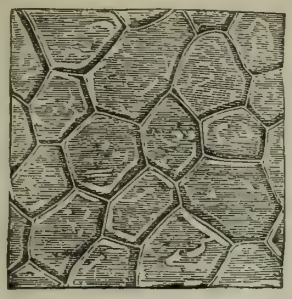

Fig. 2.—Section of the Shell of Pinna parallel to the surface, showing Prismatic Cellular Structure, cut transversely, magnified 185 diameters.

in the case of many other tissues, the original cellular organization often becomes so hidden by subsequent changes, as to cease to be recognizable. The typical condition of the shell in this subkingdom is best seen in certain bivalves—the genus *Pinna*, for example. On breaking off a small portion of the projecting margin of one of these shells, and examining it under the microscope, it is found to be made up of a vast number of prisms, hexagonal in form, and nearly uniform in size, which are arranged perpendicular to the surface of the lamina of the shell, so that the thickness of the lamina is formed by their length, and its surfaces by their extremities. On submitting such a lamina to the action of a dilute acid, the calcareous salts are dissolved, and a membrane is left which shows the prismatic structure as perfectly as it was seen in the original shell, the hexagonal divisions being evidently the walls of cells resembling those occurring in the pith or bark of a plant.

It sometimes happens in recent, but more commonly in fossil shells, that the animal matter decays and leaves the prisms ununited, and easily separable from one another. It is only in a few families of bivalves that the cellular structure is seen in this very distinct form, or that it makes up a large portion of the shell; and these families are closely allied to *Pinna*. In many shells, the

Fig. 3.—Calcareous Prisms of the Shell of Pinna, from Chalk.

external layer is formed on the above plan, while the internal layer is nacreous; in many, again, the nacre, or 'mother of pearl,' and in others sub-nacreous structure, constitutes nearly the whole thickness of the shell. The nacre, according to Sir D. Brewster, consists of a multitude of layers of carbonate of lime, alternating with animal membrane; and the grooved lines on which iridescent lustre depends, are due to the wearing away of the edges of the animal laminæ, while those composed of carbonate of lime stand out; it is, however, more probable, from Dr. Carpenter's researches, that the peculiar lineation of the surface of nacre is due to the disposition of a single membranous layer in folds or plaits, which lie more or less obliquely to the general surface.

In the *Crustacea*, the structure of the shell has only been ex-

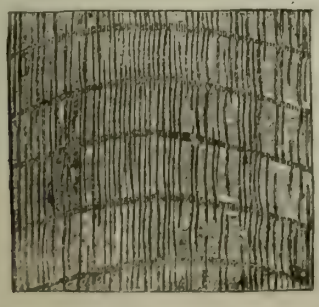

Fig. 4.—Portion of transverse section from Claw of Crab, magnified 400 diameters.

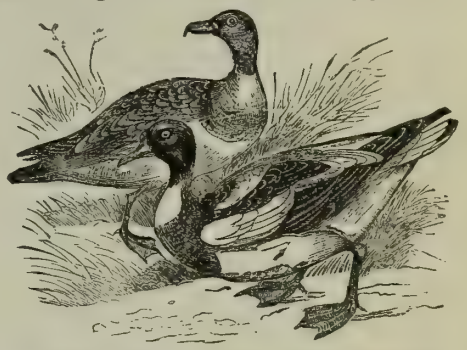
amined in the order of Decapods. In this order—in the common crab, for example—the shell consists of three layers, viz. (1) an external horny epidermic membrane covering the exterior; (2) a cellular or pigmentary structure; and (3) an internal calcareous or tubular substance. The horny layer is easily detached after the shell has been for some time immersed in dilute acid; it is thin and tenacious, and presents no trace of structure. The pigmentary layer is very thin in the crab and lobster, but is much thicker in some other Decapods. The internal layer is that which constitutes the chief part of the shell; it is in this layer that the calcareous matter is chiefly deposited; but even after this has been removed, a very distinct animal basis remains, which closely resembles that which is left after the dentine of the teeth has been deprived of its inorganic constituents, as may be seen in the accompanying figure, representing a transverse section from the claw of the crab; the dark lines representing minute tubules.

For further information on this subject, the reader is referred to Dr. Carpenter's various articles on the Microscopic structure of Shells, and especially to his article 'Shell' in the *Cyclopædia of Anatomy and Physiology* (from which the materials of the present article have been almost entirely drawn), and to his *Microscope and its Revelations*.

SHE'LLDRAKE or SHIELDRAKE (*Tadorna*), a genus of ducks of the section having the hind-toe without any pendent membrane.



Shelldrake, female and male (*Tadorna vulpanser*).

The shelldrakes are a connecting link between geese and ducks, having much resemblance to the former. The species are mostly natives of the southern hemisphere, but the COMMON S. (*T. vulpanser*, or *Bellonii*) is common on the sandy sea-shores of Britain; many coming from the north for the winter, and some remaining all the year, and breeding, making their nests in rabbit-burrows or other holes in soft soil, whence in some places the S receives the name of *Burrow Duck*. It is a beautiful bird, the sexes nearly alike in plumage; the head and upper part of the neck green, with a collar of white, and a lower collar of rich chestnut, extending over part of the back, the rest of the back white. The whole length is fully two feet. The S. is very capable of being tamed, and breeds in domestication. Its note is a shrill whistle. Its flesh is coarse and unpalatable—The RUDDY S. (*T. rutila*), the only other European species, is rare as a British bird, although common in many parts of Europe and Asia.

SHELLEY, PERCY BYSSHE, the eldest son of Sir Timothy Shelley, Bart., the representative of an old Sussex family, was born at Field Place, near Horsham, in that county on August 4, 1792. His earlier education he received at home with his sisters. About the age of ten he was sent to a school near Brentford, and thence, three years after, transferred to Eton. Shy and sensitive yet self-willed and unsubmissive, he suffered much from the harsh discipline of masters and the tyranny of his ruder associates. In his refusal to fag at Eton, he gave early indication of that passionate impatience of every form of constituted authority not approving itself to his reason which continued through life to distinguish him, and to find expression in his writings. In 1808, he left school, and after two years passed at home, he was sent to University College, Oxford. Even thus early, he had become a free-thinker of a somewhat advanced kind, and a pamphlet, entitled *A Defence of Atheism*, which he circulated during the second year of his college course, led to his expulsion from Oxford. This so irritated his father, that for some time he declined to receive him; and on his rash marriage, in August 1811, to a Miss Harriet Westbrook, the daughter of a retired innkeeper, the estrangement between them became final and complete, the old gentleman consenting to allow his son a liberal yearly income, but never after having any intercourse with him. S.'s marriage was in its issue tragical. In 1813, a separation took place between him and his wife, who, with two children, returned to the care of her father; and three years after, the unhappy woman drowned herself.

The refinements of intellectual sympathy which poets desiderate in their spouses, S. failed to find in his wife, but for a

time he seems to have lived with her not unhappily; nor to the last had he any fault to allege against her, except such negative ones as might be implied in his meeting a woman he liked better. This was Mary Godwin, a daughter of the celebrated William Godwin and Mary Wollstonecraft, with whom, in 1814, he travelled in France and Switzerland, and who afterwards became his second wife. Such excuse of his conduct in the matter as the theory of 'congenial souls' may afford in the eye of the moralist must to the full be allowed for S., whose later union was of almost ideal felicity and completeness. On the death of his first wife, he laid claim to his children; but this their grandfather, Mr. Westbrook, strange as it may now seem, successfully resisted at law on the ground of his atheism, as exhibited in the poem of *Queen Mab*, which a year or two before he had printed, though only for private circulation. In 1815, while living at Bishopsgate, near Windsor, he wrote his *Alastor*, one of the most finished and characteristic of his works; which was followed by *The Revolt of Islam*, composed in 1817 at Marlow.

During the interval, in the course of a tour in Switzerland, he had formed the acquaintance of Lord Byron, with whom afterwards in Italy he had much intimate intercourse. In March 1818, he left England finally—as it proved—to proceed to Italy; and during that and the following year, chiefly while a resident in Rome, he produced what may rank as his two finest poems—the grand lyrical drama of *Prometheus Unbound* and the tragedy of *The Cenci*. While at Venice with Lord Byron in 1820, he wrote *Julian and Maddalo*, a record in enduring verse of an interesting conversation of the discussional kind between the noble poet and himself. His other works of chief importance are: *Rosalind and Helen*, begun before he left England; *The Witch of the Atlas*, written in 1819; *Epipsychidion; Adonais* (a lament on the death of Keats); and *Hellas* (a lyrico-dramatic burst of exultation on the outbreak of the Greek war of liberty)—all three produced in 1821. The winter of 1822, S. passed at Pisa; and in the April following, he established himself near Lerici, in the Gulf of Spezia. His fondness for boating had through life amounted to a passion, and here he indulged it to the full. On July 8, 1823, in the company of an ex-naval friend, Mr. Williams, he sailed from Leghorn, whither he had gone to welcome his friend, Mr. Leigh Hunt, to Italy, and was lost in a sudden squall on his voyage homeward. The bodies were, after some time, washed ashore, and were burned, as the quarantine law of the country required, in presence of Lord Byron, Mr. Leigh Hunt, and another inimate friend, Mr. Trelawney. S.'s ashes were carefully preserved, and lie buried in the Protestant cemetery at Rome, near the grave of Keats.

In S.'s opinions, religious, social, and political, crude as they often were, and everywhere expressed with an unwise reckless vehemence, there was much that might reasonably offend; and they not only on their own account roused against him a storm of obloquy, but made him throughout life the accredited mark of the most foul and malicious slanders. To this chiefly it is to be attributed that, whilst he lived, his genius met with no wide appreciation; but since, it has been amply recognized, and perhaps no writer of his time at this day ranks higher on the whole than he. In sustained lyrical impetuosity, S. surpasses every other writer; his diction is not more remarkable for its opulence than for the expressive subtlety and precision with which it defines the nicest refinements of feeling and thought; and his page flashes with imagery like a royal robe rich with gems. But too often, whilst he dazzles, he also bewilders; he is fond of supersubtle abstractions, unsubstantial as clouds or dreams; and frequently in reading him we seem merely to be looking on wreaths of rainbow-colored mist. This want of clear and firm outlines is more or less felt throughout all his larger works, with the single exception of *The Cenci*, in which a terrible story of real life is dramatized with consummate vigor and directness of treatment. As to the matter of the rest of his poems, they concern themselves, for the most part, not with the world as it is or has been, but with a perfected world which is to be. S. is the *vates* of the future, as Scott is the poet of the past. Of the charge of atheism against S., it is enough to say that it rests mainly on his boyish poem of *Queen Mab;* that this he did not himself give to the world; and that when, in 1821, it was surreptitiously published, he issued an express protest against his being held answerable for any opinions set forth in it. In his later works, a vague Pantheism seems indicated; and one or two passages occur which fairly admit of a purely theistic interpretation. The most complete edition of S.'s works is that by J. Buxton Forman, published in 1880 (the poems in four volumes, the prose writings also in four volumes). See Medwin's *Life of Shelley* (1849); Trelawney's *Recollections of the Last Days of Shelley and Byorn* (Lond., 1858); the *Shelley Memorials*, by Lady Shelley (1859); *Shelley's Early Life*, by D. MacCarthy (1872); and lives by G. Barnet Smith (1877), and J. A. Symonds (1878).

By common testimony of all who knew him, S., who was held up to execration as a perfect monster of iniquity, was one of the purest, gentlest, most lovable of men; of the tenderest private affections, and, beyond the immediate circle of these, of the largest flowing charity. The passion of philanthropy expressed in his writings found as practical an expression in his daily life as if he had never made any very great profession of it. The episode of his first marriage seems more or less awkward for him; but the one passionate frailty of a boy can scarcely be held a serious blemish on a man whose whole subsequent life was exceptional in virtue and beneficenee.

Mary Wollstonecraft Godwin, wife of the poet, was born in London 1798, married Shelley, as above stated, in 1816; and in the same year produced a remarkable novel, entitled *Frankenstein*, the hero of which, a profound student of nature, discovers the secret of creating life, and produces a monster whose history, though wild and horrible in its incidents, is invested with a strong human interest. The work had a great success, and may be reckoned the best of Mrs. Shelley's literary efforts. Other novels of hers are *Valperga*, *The Last Man*, *Lodore*, and *The Fortunes of Perkin Warbeck*. She likewise wrote, *Rambles in Germany and Italy;* a series of biographies of foreign artists and poets for the *Cabinet Cyclopædia;* and edited her husband's poems. She died Feb. 1, 1851. See *Mary Wollstonecraft*, by Paul (1878).

SHELL-GUN belongs rather to the past than the present, as in modern rifled artillery all guns fire shells. Before their introduction, however, shells were fired from guns of large bore, and proportionately small thickness of metal, not differing materially from howitzers, except that they had greater length.

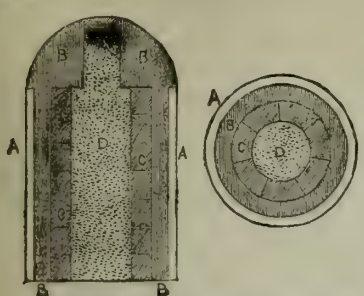
SHELL-LAC. See Lac.

SHELLS, called in earlier times bombs, consist of hollow vessels of metal, containing gunpowder or other explosive compound, so arranged that it shall explode at a certain point, and spread destruction around by the forcible dispersion of its fragments. The invention of this murderous missile cannot be accurately traced. Shells were employed in 1480 A.D., by the sultan of Gujerat, and by the Turks at the siege of Rhodes, in 1522. The Spaniards and Dutch both used them during the war of Dutch independence; and they appear to have been generally adopted by about 1634. As shells required Mortars (q. v.) for their projection, they were not used in naval warfare until the French constructed special bomb-vessels in 1681; but since that period, shell-guns, being cannon of large bore, have been introduced, and shells are now employed by all ships of war.

Until within a few years, every shell was a hollow sphere of cast-iron, varying in thickness from half an inch to two inches, and in diameter from five and a half inches to thirteen inches. The sphere had a fuse-hole (like a bung-hole) an inch across, through which the charge was inserted, consisting of pieces of metal and powder to burst the shell. The hole was plugged by a fuse, which was a tube of slow-burning powder, timed to communicate fire to the charge after the lapse of a certain number of seconds. This fuse might either be kindled by hand the moment before the mortar was fired, or its ignition might be effected by the act of firing itself. The Shrapnell shell, introduced by Colonel Sharpnell of the Royal Artillery about 1808, contained a number of bullets, and being fired at bodies of men, it was timed to explode about 100 yards before reaching them, when the shell burst, and the bullets with the fragments continued their course, diverging continually as they went, until they reached their object in a death-cloud. The *Concussion shell*, or *Percussion shell*, is one in which the charge is fired by the detonation of a cap on striking an object. If sufficiently delicate to explode on touching a soft object, and at the same time not to be exploded by the resistance of the air to its rapid flight, this form of shell is the most certain in execution.

Since the introduction of rifled ordnance, the shell has become the commonest form of projectile. It has ceased to be spherical, and is usually in the shape of an elongated bolt. Several rival shells at present divide public favor, and compete for adoption into war service. Without noticing the numerous varieties which are in course of trial on the continent and in America, the following are the principal British competitors. The *Armstrong* shell is a pointed bolt of iron (usually percussion), containing an inner 'segment shell,' made up of 49 segments of cast iron. Seven of these segments form a circle, or ring, and seven circles give the necessary length. A coating of lead affords a soft medium for fitting into the grooves of the gun. The shell thus made somewhat resembles a bottle without the neck. The necessary bursting charge having been inserted, the rear-end is plugged with lead, the fuse is screwed into the front, and the shell is ready for action. This projectile has a great and accurate range, and its segments cannot fail, on explosion, to do great damage. The principal drawback has been found in the lead-casing, which is often thrown off in parts soon after the shell leaves the gun, and which thus falls among the foremost ranks of the army using it, sometimes inflicting severe wounds. The *Whitworth* shell is an elongated hexagonal bolt of iron or steel, cast in one piece, and with a bursting charge at the rear-end. It explodes on percussion;

but the space allowed for the burster is deemed insufficient to produce the full effect which the length and correctness of the weapon's range give cause to expect. The *Lancaster* shell is oval, to fit the bore of the *Lancaster* gun (q. v.). *Martin's* shell is charged with molten iron, which sets on fire all combustible matter on



Armstrong Shell:—A, lead casing; B, outer shell; C, segments; D, charge.

Whitworth Shell.

which it can be thrown. The *Diaphragm* shell, invented by Colonel Boxer, R.A., has an iron division or diaphragm to separate the powder in the shell from any balls or slugs, in order that the friction of the latter may not prematurely cause the powder to explode. A six-pounder diaphragm shell contains 30 carbine-balls; an eight-inch shell, 322 musket-balls. The Palliser shell, which is now employed in the British service, is chiefly remarkable for the hardness imparted to its fire-point by a process of 'chilling' during casting. This gives it a great power of penetration into iron plates, &c.

SHELL-SAND. Sand consisting in great part of fragments of shells, and often containing a small proportion of organic matter, is a very useful manure, particularly for clay soils, heavy loams, and newly-reclaimed bogs. It is also advantageously applied to any soil deficient in lime. It neutralizes the organic acids which abound in peat, and forms with them compounds which serve as food for plants. Great deposits of shell-sand are found on the coasts of Devonshire and Cornwall, and are of great value in the agriculture of that district. Shell-sand is also found on many other parts of the British coast, and nowhere more abundantly than in the Outer Hebrides. The sand of many parts of the coast, however, being mostly silicious, is incapable of the same use. Shell-sand is much used as a manure in some of the maritime districts of France, as Bretagne and Normandy.

SHEMA'KHA, the former name for what is now known as the government of Baku, occupying the south-east portion of Transcaucasia. Area, 14,915 sq. m.; pop. (1880) 540,800. North of the Kur, and around its mouth, the surface is level, low, and fruitful, though little of the surface is under cultivation. Only in the towns and seaports, and the villages in their vicinity, are agriculture and industry pursued. The mountainous regions are inhabited by a rude predatory population.

SHEMAKHA, the capital of one of the six circles in the gov. of Baku, about 70 m. W.-N.-W. of the town of Baku. Formerly a thriving town, with silk and other manufactures, it was destroyed by an earthquake in 1859. After having been rebuilt, it was again destroyed, all but entirely, by another earthquake in 1872. It has a pop. of 26,000.

SHEMI'TIC (Semitic*) LANGUAGES the general name of a certain number of dialects, supposed at one time to have been spoken by the descendants of Shem. The term is of recent origin (Schlözer, Eichhorn), and a misnomer; for, in the first place, not all the nations derived in Genesis from Shem spoke an idiom akin to those understood by the term Shemitic (e. g., the Elamites, Lud, &c.), and, on the other hand, Canaan and Cush, whose Shemitic speech is undoubted, are there traced to Ham. Shemitic Languages, however, as a 'conventional appellation,' is still the best of all the general terms hitherto proposed (Arabic; Syro-Arabic, analogous to Indo-Germanic).

The family of Shemitic languages, which spread originally over Canaan (Phœnicia and Palestine), Assyria, Aram (Syria, Mesopotamia, Babylonia), and Arabia; and, at a later period, over part of Asia Minor and the Punic northern coast—i. e., from the countries on the Mediterranean to the Tigris, and from the Armenian Mountains to the south coast of Arabia—may broadly be divided into three principal classes: 1. The Aramaic or Northern (north-eastern) dialect, comprising, chiefly, the so-called Chaldee and Syriac; 2. The Southern, the chief representative of which is the Arabic, closely allied to whose older (Himyaritic) form is the Ethiopic; 3. The Middle, or principally Hebraic, to which also belong the languages of the other Palestinian inhabitants, those of the Canaanites and Phœnicians above all. The difference between the Middle and Northern branches, is less sharply marked, than between the Middle and the Southern or Arabic.

Before proceeding to treat of them individually, we shall try to point out their general position among other languages, and principally, the salient points of difference between the Shemitic and that other most important family of the Indo-Germanic or Aryan languages. First of all, then, we notice the preponderance given in Shemitic to the consonants in contradistinction to the vowels. The former are indeed the basis and the body of the words. The vowels are more or less accessories, modifying, fixing, precising the meaning, but never themselves containing it, while in the Indo-Germanic languages the root itself consists generally of a combination of vowels and consonants. A further peculiarity is the prevailing 'triliteralness' of Shemitic roots in the advanced stage in which we now know them. The Indo-Germanic languages derive their wealth from the logical law of their composition of roots, of verbs, and particles; the Shemitic add to their store in phonetically multiplying their sounds: either by splitting, as it were, their single consonants into two or more, through the reduplication of radicals, or by the addition of new consonants to the primary root, which is thus developed often from a monosyllabic (for by far the greatest number of Shemitic roots consisted primarily of two consonants only to which a third was generally added at a later period) into a root of five letters. Compound words are of the utmost rarity both in the noun (except proper names) and the verb, and they never consist of combined roots of verbs and particles, but of verbal and nominal roots. Regarding the formation of cases, tenses, and all those other grammatical changes of noun and verb which, in the Indo-Germanic family, are wrought—as far as the verb or noun itself is concerned—almost exclusively by suffixes, while the radical vowel changes merely according to euphonic rules within its own limited sphere, the Shemitic languages, principally and chiefly work their flexions by a change of vowels within the radical consonants, leaving the latter themselves intact. Only when these changes suffice no longer for the more elaborate modes of speech and thought, supplementary letters and syllables are sought in aid, and a certain small number of prefixes or affixes represents the vast and varied groups of little words (amounting at times to whole phrases) of the Indo-Germanic.

The Shemitic languages are also, if poorer, less complicated in forms than the former family. There are only two genders—which, however, are also distinguished in the second and third persons of the verb—and two principal tenses. These are strongly marked by the position of the personal pronoun, represented by a suffix in the so-called perfect and by a prefix in the so-called aorist or imperfect (future). The former expresses the finite, the completed action, the fact; the latter, the incompleted action, the thought, that which is becoming, growing, as it were, into a fact. One of the most curious features is the sudden change that may be produced in the two by a certain prefixed conjunctive-consonant. Perfect then becomes future, and *vice versâ*. Declension, in the Indo-Germanic sense, exists, if at all, in an extremely limited sense in Shemitic. The juxtaposition of two words (with slight vowel-changes) forms the genitive, while the other cases (in the Hebraic at least) are formed by prepositions. The oblique cases of pronouns are indicated by suffixes. The syntax is of the crudest and simplest description: a mere stringing together of sentences without any particular attempt at a logical and methodical arrangement of periods, according to their temporary superior or inferior relation to the subject-matter.

Another most important point of distinction between the two families is formed by what has been called their lexical difference, i. e., the want—except in a few isolated cases—of any correspondence or identity in their individual words. Most of those words which exhibit a similarity, can be shown to have been either adopted at a late period, or they simply fall under the category of onomatopoeic words (words imitating the sound of the object expressed, and therefore showing in all cases greater or smaller affinity to the original sound); or, again, words in which the common type of human language would involuntarily, and under all circumstances, connect a special meaning with a special sound, and would, therefore, be more or less identical in all idioms.

Of words introduced into European languages by Shemitic (Phœnician) traders may be instanced, *kanua* = cane, *gamal* = camel, *mor* = myrrh, *kezish* = cassia, *ahelim* = aloe, *nerd* = nard, *carkon* = crocus, *sappir* = sapphire, *sak* = sack, &c. Of onomatopoeic terms, *lakak* = (Sansc. *lih*) to lick, *charat* (Sansc. *charidan*) = to grate, scratch, *galal* = to roll, *parak* = to break, &c. On the other hand, words have crept into Shemitic from foreign languages; e. g., the Egyptian, *ior*, *iero*, *iaro*, river, Nile, is found as *yeor* in Hebrew, *pardes* (Heb.) paradise, is Persian, *kop* (Sansc. *kapi*) is the Heb. for ape, *karpas* (Sansc. *karpása*) = wool, cotton, &c.

As regards the age of the family of Shemitic languages, it is

* In Hebrew, the name from which the adjective is derived, is spelt *Shem;* but, as in many other cases, the *sh* of the original was transformed by the Septuagint into *s* (see SHIBBOLETH); and hence, through the influence of the modern versions that have in this respect followed the Septuagint, the form *Semitic* is more current among continental writers than *Shemitic.*

matter of great doubt whether or not they were developed earlier than any other, e. g., the Indo-Germanic. The monuments that have survived are not sufficient for us to form a final judgment as yet. It stands to reason, however, that a development may have taken place simultaneously and independently in the idioms of other nations. The notion long cherished (and still upheld by a few isolated speculators) that Hebrew was the original language of all mankind up to the episode of the tower of Babel, may here be passed over without remark. See PHILOLOGY.

We shall now endeavor to draw an outline of the relation of the Shemitic languages among themselves, and to cast a rapid glance at their individual characteristics and history, referring for fuller details to the articles devoted to the special branches indicated. Although the Shemitic languages are clearly sister dialects, their relationship is far from being so close as, for instance, that of the different Greek dialects. Thus, Abraham, belonging by his descent to a people of Shemitic tongue, and coming from a country where Shemitic was the general language, at his arrival in his new place of abode, inhabited by Shemites, was considered, and considered himself a foreigner to a much greater extent than it would have been the case had a Greek emigrated from one part of Greece into another.

It would be more fit perhaps to institute a comparison between the different Shemitic dialects and the Germanic languages among themselves: German, Dutch, Danish, Swedish, Norwegian, &c.; or the Slavonic idioms: Lithuanian, Lettish, Russian, Polish, Bohemian. But even these are not so far removed from each other as the Shemitic idioms. What the latter have in common are those grammatical and other characteristics indicated above, and the *root-words* themselves, which nearly everywhere have the same original signification; only that in this respect the Arabic shows by far the largest development of meanings out of the single roots, and consequently an unparalleled wealth of derivatives. Yet it must not be forgotten that our relics of ancient Hebrew are of a scanty nature, and that the Arabic has remained a living language until our day, and has, through Islam, spread further than any ancient and perhaps even modern language.

Regarding the much-vexed question as to which of the Shemitic languages is the oldest, it must be confessed that no positive result has yet been attained. For although the oldest palpable monuments of Shemitic have survived in Hebrew, while our earliest documents in Aramaic date from Cyrus, and those in Arabic, even centuries after Christ (Himyaritic, Ethiopic, 4th c.; northern Arabic, 6th c. A.D.), yet we cannot now decide which of these has preserved the type of the original mother-tongue most intact. It sometimes happens that vast internal movements, or a series of events in the history of a people—wanderings, wars, and the like—change, quicken, and develop its language even to decay, before it has had time to beget a literature. When this time does arrive, we meet already with all the traces of this decay in perfections, corruptions, and archaisms of form.

Thus, the Hebrew of the Bible, that is the most ancient form in which it has survived, offers more grammatical analogies (in incomplete structure, inflexion, &c.) to the modern than to the ancient Arabic, which lasted in its primitive purity and fulness of form as long as the simple life of the dwellers in the desert was not broken by those events which upheaved, from the time of Mohammed, their whole existence, and brought them in closest and most violent contact with other nations of other tongues. Then that process of decomposition, or phase of negligence and corruption, set in, which resulted in the looseness exhibited by modern Arabic. It thus reached the downward stage of the Hebrew of the Old Testament at ever so much later a period. Arabic classical literature thus exhibits, compared with the Hebrew, and even more with the Aramaic—which we meet in a worse state of aged and crippled organism and stunted form—about the same vigor freshness, and fulness of form and structure, which the Sanscrit exhibits among the Indo-Germanic or the Gothic in the narrower circle of the Germanic dialects. With all this, however, we cannot absolutely decide in favor of the Arabic as the nearest approach to the original type. The phase in which it enters into our historical horizon may be as far if not further removed from it even as the Aramaic. Its hasty individual development may have quickened more radical changes than even the decaying or decayed other branches present. So that, as we said, for the present at least, the question of priority must remain open. We shall, however, allot the first place to the second or Southern Shemitic (Arabic) class, simply because of its copiousness of words and development of forms. A faint trace of its peculiarity of article (*al*) is supposed to be found in Gen. x. 26 (*Almodad*); but this seems fallacious enough, considering that the Hebrew article must have been originally the same, and the word may simply exhibit the ancient Hebrew form.

In the golden epoch of Hebrew literature, Arab culture does indeed seem to have stood in high renown—Solomon's wisdom is likened unto that of the Arab's, Queen Sheba is an Arab queen, and Job's friends are Arabs. On its peculiar history and development, however, we cannot here dwell. (See ARABIAN LANGUAGE and LITERATURE). Suffice it to observe generally, that Arabic is not only the richest of Shemetic, but one of the richest of all languages, with its more than 6000 word-roots, and about 60,000 words; while the Hebrew has about 2000 of the former and 6000 of the latter. The 22 consonants of the Aramæans, and the 23 of the Hebrews, have been augmented into 28 with the Arabs. They further have twice the number of the Hebrew regular conjugations, in which, again, the latter exceed the Aramaic by one. The same abundance is noticeable in the Arabic tenses, declensions, &c. The general wealth of this language, however, will be best appreciated by its possessing some thousand different terms for a sword, and a proportionate number of words for lion, serpent, and the like; while on the other hand, its adaptibility and versatility is shown by one word often possessing a vast number of meanings. Anciently, it had two principal branches: the Himyaritic spoken in the south, which has perished almost completely (a few partly mutilated inscriptions, recently brought to the British Museum, have been published some time ago, and their interpretation has been attempted by Osiander and Levy in the *Germ. Or. Society's Transactions*), and the Koreishite, which, being the idiom of Mohammed's tribe, became *the* paramount Arabic for all times. The Ethiopic (see ETHIOPIA) is by some investigators held to have flowed from the Himyaritic; but from the 14th c., the Amharic dialect (also Shemitic, but with little capacity for writing purposes) has superseded the Ethiopic almost completely.

The North Shemitic or Aramaic, to which we now turn, is the language of the whole district between the Mediterranean and the Tigris, south of the Taurus, north of Phœnicia, the Israelitish territory, and Arabia. Here we have again to distinguish between Syria Proper, Mesopotamia (between Euphrates and Tigris), and Babylonia (south of Mesopotamia), whither the Israelites were carried by Nebuchadnezzar. Yet, with respect to this latter country, it can hardly be doubted that another dialect besides the Aramaic was spoken in it. But whether this was 'Medo-Persian,' ('like the Assyrian'), or some other 'Turanic' idiom, largely mixed with Shemitic ingredients, must remain doubtful until our knowledge of 'Turanian' and our reading of cuneiforms shall have advanced somewhat further. There is, however, but one voice among competent investigators, that whatever strange elements the Babylonian and Assyrian languages may contain, they have a full claim to be reckoned among the Shemitic. The Aramaic in general is, as has been observed before, poorer than the Hebrew in grammatical forms, vowels, &c., besides having a peculiar tendency to blunting its consonants, changing its soft *s* into *d*, *ts* into *t*, *sh* into *th*, and the like. It further does not express its article by a prefix, but by an *Alef*, and it forms its passives, not by a change of vowels, but by a special syllable prefixed to the root. The first distinct trace of a difference between Hebrew and Aramaic is found in Gen. xxxi, 47, where it is found necessary to translate Laban's designation of the stone-heap erected in memory of his peace with Jacob. Although the ancient Babylonians had, in all probability, a rich and important literature; yet nothing of it has survived. The so-called Babylonian fragments supposed to have comè down in Arabic translations are a mere fiction.

All the Aramaic literature which we now possess is derived from the Jews, and of a very late date. The Babylonian exiles, both those who returned to Palestine and those who stayed in the land of their captivity, made Aramaic their habitual language. It was the common tongue of Palestine at the time of Christ, the Hebrew being then chiefly the 'holy language'—i. e., the language of temple and synagogue. Thus, the Shemitic words used in the New Testament are one and all Aramaic (Mammon; Raka; Eli, Eli, &c.; Talitha Kumi; Abba; &c.), and the same may be said of the Shemitic terms found in Josephus. The oldest remains in this idiom (variously called Hebraisti, Arami, Sursi, Chaldee) are certain portions of the Old Testament (Daniel, Ezra, &c.), the Targums (q. v.), the Mishna (to a certain extent, at least), the Talmuds, and the Midrashim. Idiomatic shades are again observable in these different documents; but while, as a living language, it was spoken and pronounced differently in the different districts of Palestine and Babylon, yet the special subdivisions into special provincial dialects which have been attempted can hardly be said to be correct. From the 2d. c. A.D., Christian writers, chiefly in Mesopotamia, Edessa, Carrhæ, Nisibis, began to use this language in their writings, which are principally theological (Translation of the Bible) and dogmatical, but which also treat of medicine, history, philosophy, mathematics, &c. Yet their Aramaic assumed a character so essentially different, that, in some respects at least, it became an entirely distinct dialect, viz., Syriac, which, at a later period, assumed also—to make the breach complete—an alphabet of its own (Estrangelo). Many have been the attempts to account for this strange difference (the very existence of which was, on the other hand, almost totally denied at one time), but with no satisfactory result. Certain it is that the mere geographi-

cal reasons (East and West Aramaic, &c.) do not hold good, and are arbitrary and fallacious.

The Syriac, as a living language, ceased to be spoken since the 10th c., and only a few Syrian Christians in Kurdistan and Mesopotamia are supposed to use a kind of vulgar Aramaic. Syriac literature ceased about three centuries later. As the language of the church, however, it is still in use with the Jakobite, Nestorian, and Maronite branches of the Syrian church. Minor sister dialects of Aramaic are the Samaritan, a corrupt Judæo-Aramaic mixed with Arabic words; the Zabian or Nazaræan (Mandaic), the language of a theosophical sect ('disciples of John the Baptist') standing between the Syriac and Chaldee, and mixed with Persian, but bearing altogether the stamp of an uncouth, ungrammatical, sadly-neglected idiom; further, the Palmyrene (Palmyra), which, with a written character closely akin to the square Hebrew, offers but little variations from the Syriac; and finally, the Ægypto-Aramaic, which is found on a few monuments (Stone of Carpentras, Papyri), and probably belongs to Jews, who, at a late period, had immigrated into Egypt, and had adopted the Egyptian religion. Its words are principally Judæo-Aramaic, but with a large infusion of foreign elements.

The third principal branch, the Middle Shemitic, which comprises Hebrew and Phœnician (Punic)—and all the questions connected with these—have been discussed at some length under JEWS and PHŒNICIA; to which we refer. See also the special articles ARABIC, CHALDEE, ARAMAIC, &c.

SHEMITIC NATIONS, or SHEMITES. The different nations generally comprised under this name, viz., the Assyrians, the Chaldæans or Babylonians, the Syrians, Phœnicians, Hebrews, Arabs, and Ethiopians, are all treated specially in the course of this work; it only remains here to add a few observations on the characteristics ascribed to them all in common, and on the influence they have exercised upon the history and development of humanity.

As regards the language, the poverty of the inflections, the well-nigh absolute impossibility of expressing abstract ideas, the general absence of compound verbs and substantives, and the primitive state of the syntax in the Shemitic as contrasted with the wealth and vigor of the Aryan, have been noticed in the previous article. From this arises, as an almost natural consequence, the general inferiority of Shemitic literature—to what we emphatically call 'classical literature.' Certain most important forms of Indo-Germanic poetry, for instance, are completely wanting in the Shemitic, such as the epopee and the drama; although, on the other hand, the peculiar ancient form of Arabic poetry—the Kasida—and the grand bursts of pathos found in the religious books of the Hebrews, are vainly sought in Indo-European literature. Again, a primitive state of Law seems to have developed among the Aryan nations, the chief characteristic of which was a recognition, albeit a dim enough one, of individual rights, in as far as they did not war against the complex unity of the 'State.' With the Shemites, in the absence of that talent for organization and conciliation which is so essential a mark of the Indo-Europeans, we find either a patriarchal, an anarchical or a despotical kind of government. Science and philosophy, in the larger sense of the word, are the almost exclusive property of the Aryans. The inferiority of the Shemites in these respects, however, is amply counterbalanced by the sublime place they take as the ethical teachers of all humanity. How the hard and narrow egotism which, not quite unjustly, is ascribed to them, ever came to bear and ripen those grand moral maxims with which we meet in the earliest Jewish records, and which, wrought up to their purest idealism, form the shining glory of the New Testament, is a problem of which some seek the solution in a peculiar *intensity* of character inherent in the Shemitic races; while others account for it by direct 'Inspiration.' The same may be said of that Monotheism which belonged, in the first instance, to the Hebrews out of all the nations of the earth. It is a grave mistake, however, to describe, as Renan does, the Shemites indiscriminately as monotheists.

Babylon and Assyria, and Syria or Phœnicia, and the ante-islamic Arabs, were neither more nor less polytheistic than the early or present inhabitants of India. And, we may well add, not before the return from the Babylonian exile are the Jews themselves, as a body, to be considered as real monotheists. But ever since, both they, and, from the time of Mohammed, the Arabs, have been the representatives of a more austere and exclusive dogma of the unity of the godhead, than a great part of the civilized world has found good to accept up to this day. Both Christianity and Islam, the most powerful religious agents, the one for nearly two thousand years, the other for about twelve hundred, are in their origin Shemitic, and their influence need not here be enlarged upon. For what we owe to the Shemites in the field of industry and inventions, and the civilization these carried with them wherever they were imported, we need only refer to PHŒNICIA. Nor ought we to forget that the very Alphabet itself is of Shemitic origin.

SHEMITIC PLURAL. The Shemitic languages, particularly the Hebrew, often use the plural where other languages only make use of the singular. This is particularly the case in terms of space and time—their vastness being conceived, so to say, as a multiplicity. Thus, certain regions, like Heaven—which, through the influence of the Bible language, is also with us sometimes used *pluraliter*—the expanse of water; further, the place at a person's head or feet, or even certain limbs of the body (conceived as space), like neck, face, &c.; or, again, periods of times, like youth, age, life, and special *lasting* qualities or states, like barrenness, blindness, mercifulness, and the like, are put in plural number, where we have the singular only. It is further applied to might and strength, as consisting originally of a multiplicity of elements of power. This is particularly shown in the word ELOHIM (q. v.), = a Unity of many 'Mights'—i. e., the Supreme Being. The false conclusions as to the plurality of the Divine Persons being proved by this word are best refuted by the occurrence of the plural in the word Master (Adon), Lord (Baal), when these stand unmistakably for a single human individual, and are meant to express merely his proprietorship of some object or other.

SHENANDO'AH, a river of Virginia, U. S., the largest trbutary to the Potomac, drains the beautiful and fertile valley between the Blue Ridge and the principal range of the Alleghanies. It rises in two branches near the center of the state, and runs north-east to the Potomac, 170 miles, being navigable for small boats 100 miles. In the war of 1861—1865, this valley was the scene of numerous conflicts, was successively occupied by the opposing armies, and finally laid waste by General Sheridan in the autumn of 1864.

SHE'NDY, a town of Africa, in Lower Nubia, on the right bank of the Nile, 100 miles in direct line below Khartoum. At its markets, two of which take place every week, a large variety of articles, as wheat, straw, salt, and cotton goods are sold. Near the town, which gives name to a large district, the finest senna is obtained. Pop. about 10,000.

SHENSTONE, WILLIAM, the son of Thomas Shenstone of the Leasowes, Hales Owen, Shropshire, and his wife Anne Penn, was born there in the year 1714. In 1732, he was sent to Pembroke College, Oxford. Whilst there, he devoted himself much to the study of English poetry, and in 1737 he published without his name, a small volume of miscellaneous verse. Subsequently, for some years, he lived in a somewhat vagrant way, yet without ceasing to cultivate his talent. In 1741, appeared his *Judgment of Hercules;* and next year, *The Schoolmistress*, the work by which chiefly he continues to be remembered. In 1745, his parents being dead, he established himself on his property of the Leasowes, where he thenceforth continued to reside. He busied himself with landscape gardening, and such was his success in beautifying his little estate, that it attracted visitors from all quarters, and brought him more fame than his poetry. He was thus, however, led into serious pecuniary embarrassments, from which, on February 11, 1763, a putrid fever relieved him.

The Schoolmistress, which has secured for its author a permanent if humble place among English poets, is written in the stanza and antique manner of Spenser's *Faery Queen;* and in the contrast between the stateliness of the vehicle, and the familiar and homely quality of the subject, with the graphic truth of its treatment, there is a singular source of charm. The other works of S. are for the most part quite insignificant; but his *Pastoral Ballad* has touches of exquisite tenderness and truth of sentiment expressed in a simple and appropriate melody.

SHEOL (LXX. *Hades, Thanatos*, Vulg. *Inferi*), a Hebrew term of very frequent occurrence (65 times) in the Old Testament, and rendered by the Authorized Version: grave, hell, or pit. Its derivation is doubtful: while some connect it with a root, denoting to seek, others derive it from a root, 'to dig out,' 'to hollow' (compare Germ. *Hölle*). The use of the word in the original would seem to prove a great fluctuation of the dogma respecting the world to come, during the various periods represented in the special parts of the Bible. Sometimes it does stand unmistakably for 'tomb,' although our notions of an artificially prepared grave do not originally belong to it; at other times, it is the abode of disembodied spirits, whether good or evil. It is the place where the dead go to be united with their 'people,' their 'ancestors,' friends, and all the departed. It was placed in the center of the earth, or below the ocean, and was a dismal, dark place, like the Orcus, or Tartarus. It has gates and bars, it has chambers, valleys, and rivers, and its inhabitants—the shadows—(*Rephaim* = feeble ones), who ordinarily enjoy deep repose in this 'reign of silence,' are troubled by being called up to the surface, or tremble at the arrival of some great tyrant. As the receptacle of all things, it contains the shadows even of trees and kingdoms. It is described as all-devouring, remorseless, and insatiable. There can be no doubt of the existence of an idea—however vague—if not of immortality, in the modern sense, yet

of some state after life among the Hebrews, even in the earliest times. For the Gehenna (Ge-Hinom) of the New Testament—the contemporaneous Sheol—see HELL.

SHEPHERD'S DOG, or SHEEP-DOG, the most useful and valuable of all kinds of dog, and universally employed by shepherds throughout Europe, and in the countries colonized from Europe, and also in some parts of Asia, to assist them in the tending of their flocks. Without it, the shepherd would be utterly incapable of taking care of the great number of sheep often under his charge; and the expense of keeping the requisite number of shepherds would far more than take away the profits of sheep-farming. That the dog was employed in the tending of sheep in very ancient times, we learn from the allusion to the *dogs of the flock* in Job xxx. 1. Buffon imagined the shepherd's dog to be the original of all the domesticated dogs; but was unable to assign any good reason for such an opinion. The shepherd's dog exhibits nearly the same characters in all parts of Europe, although there are slight diversities in different countries, as between that of England and that of Scotland, there known as the *Collie*. It is of middling size—differences of size, however, being amongst the characteristics of different races; of rather slender form, with a pretty sharp muzzle; the ears erect, or, in some races, drooping at the tip; the hair soft, long, shaggy, and somewhat waved; the tail slightly pendulous, more or less recurved, and very bushy; the feet well protected by hair, so as to be adapted for rough ground. The eye is very bright and intelligent, although the ordinary demeanor of the animal is remarkably calm and quiet. No kind of dog is more intelligent, and perhaps none so docile. Its ready comprehension of the meaning of its master, its prompt obedience to his word or gesture, its evident knowledge of what is requisite to be done, and the services which it performs, can never be observed without admiration.

A shepherd's dog exhibits the utmost care to prevent sheep from straying off the road along which they are being driven, and sets itself, often of its own accord, to watch any gate or gap in the fence, or goes immediately to bring back stragglers. It is equally

Shepherd's Dog, or Collie.

useful on the bleak moor or wild mountain, readily going for sheep, and bringing them from a distance. The sheep become perfectly acquainted with it, and evidently regard it as a friend, and not as an enemy, although the appearance of any other dog would alarm them at once. It knows the sheep of the flock it is required to attend, and even in a crowded market adroitly separates them from others with which they have become mingled. Its remembrance of places is obviously very accurate; and a dog which has found great difficulty in conducting sheep through crowded thoroughfares, does the same work much better on subsequent occasions. The intelligence of the shepherd's dog has sometimes been proved in a very remarkable way by dishonest masters employing them to steal sheep; the master merely indicating by some sign the sheep which he wished to add to his own flock, and leaving the dog to do it in his absence. For stealing sheep in this way, a farmer in the south of Scotland was hanged about the end of last century. More frequent instances are on record of the shepherd's dog conducting a flock of sheep safely home for many miles, unaccompanied by the shepherd. The shepherd's dog is affectionate, and becomes strongly attached to its master, but is generally shy to strangers. It is generally treated with great gentleness by the shepherd; no severity is used in its training, nor could be used with advantage. It is very muscular and active, and capable, perhaps beyond any other kind of dog, of continuing its exertions during a long time.

The shepherd's dog is often crossed with other kinds of dog, and particularly with the pointer and setter. Dogs are thus obtained, which, while capable of all the services required by the shepherd, are equally capable of being employed in the pursuit of game, and are most successful in night-poaching.

The *Drover's Dog* is very often a cross between the shepherd's dog and the mastiff, the foxhound, the pointer, or the grayhound. It displays many of the best qualities of the shepherd's dog, and if too frequently very different from it in its cruel treatment of sheep, the fault is originally that of the brutal master.

SHEPHERD'S PURSE (*Capsella*—formerly *Thlaspi—Bursa Pastoris*), an annual plant of the natural order *Cruciferæ*, a most abundant weed in gardens and cornfields in Britain, and remarkable as one of the few plants that are found over almost the whole world, adapting themselves to almost all soils and climates. It is a very variable plant, from 3 inches to 2 feet in height, with root-leaves more or less pinnatifid, all the leaves more or less toothed, and rough with hairs. The root-leaves spread closely along the ground. The flowers are white and diminutive. The pouch, from which the English name seems to be derived, is laterally compressed, and somewhat heart shaped. This is a troublesome weed where it abounds, but being an annual, it is extirpated by continual and careful cultivation.

SHE'PPEY, ISLE OF, a portion of the county of Kent, insulated from the mainland by the Swale, an arm of the estuary of the Medway, is nine miles long, and four miles broad. In early times, its dimensions were much greater, but the sea has encroached upon, and is gradually eating away, the northern shore, which is lined by cliffs of London clay, from 60 to 80 feet in height. The church of Minster, formerly in the middle of the island, is now on the north coast. Great numbers of interesting fossils are found embedded in the London clay, of which the whole island is composed. In the north of the island, corn is grown, but the south districts, which are low, are laid out in grass. Almost the whole of the inhabitants are massed in the seaport of Sheerness (q. v.).

SHE'PTON MA'LLET, a market-town of Somersetshire, five miles east-south-east of Wells. It is a town of considerable antiquity, and is mentioned in *Domesday Book* as Sepeton. Its grammar-school, free to twelve boys, was founded in 1627. Worsted stockings, crape, serge, and velvets are manufactured. It contains several large breweries. Pop. (1871) 5149; (1881) 5322.

SHE'RBET, an oriental beverage, much used in Mohammedan countries, where stimulating drinks are forbidden. It consists of the juices of various fruits diluted with water, and sweetened exactly in the way in which lemonade is made in Europe.

SHE'RBORNE, a market-town of Dorsetshire, on the river Yeo, 18 miles north-north-west of Dorchester. The King's School, founded in 1550, has an endowment of nearly £1000 a year, and several exhibitions of £40, tennable for four years at either of the great English universities. There are several silk-throwing mills. Pop. (1881) 5053.

S. was the Saxon Scireburn (*scir burna*, clear brook.) It was erected into a bishopric in 705, and remained so till 1075, when the see was removed to Old Sarum. It was a prosperous place.

SHERBROOKE, VISCOUNT. See LOWE.

SHERIDAN, RICHARD BRINSLEY, was the son of Thomas Sheridan, a lecturer on oratory and elocution, in his day of some notoriety. He was born at Dublin in September 1751, in due course was sent to school there, and afterwards removed to Harrow. He gave no promise as a boy of the brilliancy he afterwards displayed as a man, being pronounced a hopeless dunce by all his teachers. He does not seem to have been brought up to any regular employment; and after his elopement and marriage in 1773 with a Miss Linley, a public singer of great beauty and accomplishment, his prospects did not seem bright, more especially as he insisted, on a point of pride, that his wife should give up her profession. As the readiest resource he betook himself to literature. The lighter drama was the sphere which attracted him, and in January 1775, his first comedy, *The Rivals*, was produced.

Damned on its first appearance, through certain deficiences in the acting, this piece on its repetition found gradually the favor with the public which its wit and vivacity deserved, and made the reputation of the writer. In the course of the year following, S. followed up his success by a farce of no very great merit, entitled *St. Patrick's Day, or the Scheming Lieutenant*, and a second comedy, *The Duenna*, amid the sparkling dialogue of which are interspersed some songs of exquisite merit. He now became in some unexplained manner—for though his pieces were most successful, they could scarcely have brought him the necessary funds—part proprietor of the Drury Lane Theater; and in 1777, his *School for Scandal* was produced there. This, which is by much his greatest effort, instantly leaped into the popularity it has ever since continued to retain. His other works for the stage were the inimitably clever farce, *The Critic* (1779), and, after a long interval, *The Stranger and Pizarro* (1798), both adapted from the German of Kotzebue. During this interval, he was deeply engaged in politics. S.'s wit and sprightliness coruscated in society as brightly as they did in his comedies; he was an admirable table-companion—over a bottle, the best of then living good-fellows. With Fox and his wild set, these gifts made him a prime favorite; and through the influence of Fox it was that in 1780 he was returned to parliament for the borough of Stafford. In his politics, he faithfully followed Fox, and the Whig party from time to time had good service from their brilliant recruit. He never failed to

amuse the House, and when stirred by the trumpet-call of a great occasion, he was capable of rising to heights of noble eloquence. In particular, his famous speech, urging the impeachment of Warren Hastings (q. v.), is still traditionally remembered as perhaps the very grandest triumph of oratory in a time prolific of such triumphs.

In 1792, S. lost his wife; and three years after, he was married again to a Miss Ogle, who brought him five thousand pounds, to S. no doubt welcome, though trifling as a relief to the difficulties in which he had become involved, and which more and more continued to accumulate upon him. Always the most reckless and improvident of mortals, he did not improve with time. His later years were years of wretched struggle, of which debt, duns, and dissipation may furnish a convenient alliterative summary. His health failed him with his fortunes; and his friends, not finding him in his sickness and adversity quite so amusing as formerly, naturally failed him also—notably and shamefully, the Prince Regent, whose dull brains over the wine-cup he had many a time been made use of to brighten. Some honorable exceptions there were, among whom the poets, Rogers and Moore may be mentioned as steadily kind to him to the last. He died in London on the 7th July 1816, in his sixty-fifth year.

See his biography by Moore, and (for a just and delicate appreciation of his genius) Hazlitt's *Lectures on the Comic Writers*. A good edition of his works, edited by F. Stainforth, was published in 1874.

SHERI'F (Arab. noble), designates, among Moslems, a descendant of Mohammed, through his daughter Fatima and Ali. The title is inherited both from the paternal and maternal side; and thus the number of members of this aristocracy is very large among the Moslems. The men have the privilege of wearing green turbans, the women green veils, and they mostly avail themselves of this outward badge of nobility—the prophet's color—while that of the other Moslems' turbans is white. Many of these sherifs founded dynasties in Africa; and the line which, now-a-days, rules in Fez and Morocco, still boasts of that proud designation.

SHE'RIFF (A.-S. *scir-gerefa*, the reeve or fiscal-officer of a shire; compare Ger. *graf*), in English Law, is an officer whose duties are chiefly ministerial (for he has only a few trifling judicial duties). The office is of great antiquity. The sheriff was formerly chosen by the inhabitants, though probably requiring confirmation by the crown. But popular elections for that purpose were put an end to by a statute of 9 Ed. II., which enacted that in future the sheriffs should be assigned by the chancellor, treasurer, and judges. Ever since that statute, the custom has been, and now is, for all the judges of the common law-courts, with the Lord Chancellor, and Chancellor of the Exchequer, to meet in the Court of Exchequer at Westminster on the morrow of All Souls, and then and there propose three persons for each county to the crown. This is called the pricking of the sheriffs, and the crown afterwards selects one of the three nominated, and appoints him to the office. A sheriff continues in office for one year only, and cannot be compelled to serve a second time. The office is not only gratuitous, but compulsory, for if the person appointed refuses, he is liable to indictment. In practice, country gentlemen of wealth are appointed. In the city of London, the sheriffs are appointed not by the crown, but by the citizens. The sheriff has important official duties in elections of members of parliament. He is, by his office, the first man in the county, and superior to any nobleman while he holds office. He has the duty of summoning the *posse comitatus*—i. e., all the people of the county—to assist him in the keeping of the Queen's peace; and if any person above the age of fifteen, and under the degree of a peer, refuse to attend the sheriff after due warning, he incurs a fine or imprisonment. The chief legal duty which the sheriff discharges is that of executing, i. e., carrying out all the judgments and orders of the courts of law. It is he who seizes the goods of debtors or their persons, and puts them in prison. For this purpose, he has a number of persons called bound-bailiffs (or, in popular dialect, bumbailiffs), who in practice do this invidious work, and give a bond to the sheriff to protect him against any mistake or irregularity on their part.

The necessity of this bond is obvious, for the doctrine of law is, that the sheriff is personally responsible for every mistake or excess made or committed by the bailiffs in executing the writs or process of the court, and frequent actions are brought against him by indignant prisoners, or debtors whose persons or goods have been arrested; and the courts watch jealously the least infringement of personal rights caused by these bailiffs. Every sheriff has also an under-sheriff and deputy-sheriff, the latter being generally an attorney, who takes charge of the legal business.

SHERIFF, in Scotland, is a title given to three county officials, all appointed by the crown. The lord lieutenant is 'sheriff-principal,' and as such, though he performs no duties, takes precedence in the county. The 'sheriff-depute' discharged the duties of the office until recently, when the greater part of them devolved on the 'sheriff-substitute.' In Scotland, the office of sheriff is still that of a local Judge, and not merely ministerial, as in England. The institution of the office is very ancient, and the jurisdiction, both civil and criminal, was, and still is, very extensive. By the statute 20 George II. c. 43, the office was put on a better footing. The principal, or high sheriff, was debarred from performing any judicial duty, and it was enacted that none should be appointed to be a sheriff-depute but an advocate of at least three years' standing. The sheriff-depute is disqualified from acting as advocate in any cause originating in his county, though in other respects he is at full liberty to practice. He holds his office for life or good behavior. The same statute gave each sheriff-depute power to appoint a sheriff-substitute. The sheriff-substitute was at first appointed during the pleasure of the sheriff-depute, but he is now appointed by the crown, requires to be an advocate or solicitor of five years' standing, and holds office *ad vitam aut culpam*. Being bound to reside within his county or district, and prohibited from taking other employment, while the sheriff-depute usually attends the sittings of the Court of Session in Edinburgh, he, in practice, exercises the original jurisdiction attaching to the office.

The civil jurisdiction of the sheriff extends to all personal actions on contract or obligations without limit, actions for rent, and other questions between landlord and tenant. In questions affecting real or heritable property, his jurisdiction is unlimited in amount when the object is to regulate possession; but when the validity of a title is in issue, he is limited to cases where the value is less than £1000, and where the parties consent. In these cases there is an appeal from the decision of the sheriff-substitute to that of the sheriff-depute. He has also a summary jurisdiction in small-debt cases where the amount in question is not above £12; and these cases are determined without written pleadings. The sheriff does not try civil causes with a jury. In criminal cases, the sheriff has jurisdiction in all the minor offences which do not infer death or banishment, and power to award any punishment not exceeding two years' imprisonment. He has also jurisdiction in cases of bankruptcy and insolvency to any amount. In small-debt actions, criminal and bankruptcy matters, there is no appeal from the sheriff-substitute to the sheriff-depute. The sheriff's jurisdiction excludes that of the justices of peace in riots. He has charge also of taking the precognitions in criminal cases. He revises the lists of electors, and returns the writs for the election of members of parliament; and this last is almost the only duty which he performs in common with the English sheriff. An idea of the multifarious duties performed by the Scotch sheriff, may be gathered from the statement that he exercises, within a comparatively small district, the functions which in England are exercised by the commissioners in bankruptcy, county-court judges, the stipendiary magistrates, recorders, revising barristers, and coroners. The office of Commissary (q. v.) has been amalgamated with that of sheriff. Recently, large additions have been made to the sheriff's jurisdiction, and other changes are in contemplation.

The office of sheriff is one of the few which may be traced back to the Saxon times, and it appears originally to have been the same both in England and Scotland. The sheriff was (under the earl and next to the bishop) the chief man of the shire, and seems to have possessed unlimited jurisdiction to keep the peace; to have presided in all the courts; to have punished all crimes, and have redressed all civil wrongs. This extensive jurisdiction, gradually acquired at the cost of lesser local courts, has been gradually infringed upon, partly by the exercise of the royal prerogative, and partly by parliament. But in England it suffered more from the appointment to the office of men unfit to exercise judicial powers, and from the consequent usurpation of their functions by the supreme courts. The same causes operated in Scotland, though to a less extent. In England, they resulted in the almost entire abolition of the judicial functions of the sheriff. In Scotland, they resulted in his being deprived of the more important parts of the criminal jurisdiction, particularly of the power to punish by death; and in his civil jurisdiction being limited mainly to questions affecting movables. In both countries, the office was usually hereditary, which tended to a separation of the duties of the office into the honorary and the laborious—the former being performed by the principal sheriff, and the latter by the deputy. In Scotland, this separation was completed by the act of Geo. II., which entirely separated the offices, by the transference of the power of appointing the depute from the principal sheriff to the crown. In England, this complete separation has never become necessary, from the fact of the sheriff's power having been much more crippled than in Scotland. Indeed, in England, so purely honorary and ministerial has the office become, that it has been held by a female, and in Westmoreland, the office was hereditary down to 1849. The duty of enforcing the orders of the supreme courts, which now in England are a principal part of the duties of the sheriff, appears to have been engrafted on the office—probably on the theory that these orders were those of the

king himself. In Scotland, the sheriff has never been called on to enforce any writs except those actually and not merely in name proceeding at the instance of the crown.

SHERIFF-CLERK, in Scotland, is the registrar of the sheriff's court, and as such has charge of the records of the court. He registers, and, when required by the proper party, issues the sheriff's judgments. He also conducts what correspondence may be required. He has important duties to perform in regulating the summary execution which is issued in Scotland against the debtors in bills of exchange, promissory notes, and bonds, without the necessity of any judicial suit.

SHERIFF-MUIR, a name given to several moors in Scotland on account of the 'wapinschaws' which used to be there held, under the superintendence of the sheriff. The only moor of this name which appears prominently in Scottish history is situated in Perthshire, on the northern slope of the Ochils, two miles north-east of Dunblane, and was the site of the great battle between the adherents of the Houses of Stewart and Hanover, 13th November 1715. The former, who consisted of the northern clans under the Earl of Seaforth, and the western clans under General Gordon, numbering about 9000 in all, were on their march southwards, under the leadership of the Earl of Mar, to join the Jacobites who had risen in the north-west of England, when they were met by the Duke of Argyle at the head of 3500 disciplined troops. After lying under arms all night, the Macdonalds, who formed the center and right of the Highland army, attacked the left of their opponents, and routed it so completely that the fugitives fled with all speed to Stirling, carrying the news that Argyle had been totally defeated. Argyle, however, with his dragoons had meantime driven the left of the Highlanders back for two miles, when the right and center returned from the pursuit, and took him in rear; he then skilfully withdrew his men to a place of shelter, and remained facing his opponents till the evening, when he retired to Dunblane, and next day to Stirling. About 500 were slain on each side. As a mere battle, the victory lay with the Highlanders; but it was so little decisive, that it paralyzed the action of the Jacobites almost as effectually as a defeat would have done.

SHERLOCK, Thomas, D.D., an English prelate, was the son of Dr. William Sherlock, Dean of St. Paul's, and was born in London in 1678. He was educated at Eton and Catharine Hall, Cambridge, where he took the degree of M.A. in 1701. In 1704, he obtained the Mastership of the Temple; in 1714, he became vice-chancellor of his college, taking the degree of D.D. in the same year; and in 1716, Dean of Chichester. Eleven years later, he was raised to the see of Bangor, was transferred to that of Salisbury in 1734, and in 1748 to that of London. He died in 1761. S. was a strenuous Tory, and supported the Church-and-State politics of his day with a sort of dull dignity. He displayed a good deal of diplomatic skill in his different official positions, whence Bentley nicknamed him 'Cardinal Alberoni;' his eloquence and learning were likewise of a very superior order, as may still be ascertained from his 4 vols. of *Sermons* (1755—1776), which were highly praised in their day. Besides these sermons, he wrote a variety of controversial treatises and pamphlets, all of which are now wholly forgotten.

SHERMAN, William Tecumseh, an American general, born in Ohio in 1818, was educated for the army at the military academy of West Point, and received a commission as 1st lieutenant in 1841. During the war with Mexico, he served in California, and was promoted to the rank of captain. In 1860, at the secession of the Southern States, he was residing at New Orleans in a civil capacity, but went north, and at the commencement of the war offered his services to the Federal government, was appointed colonel of infantry, and was in the battle of Bull Run. Raised to the rank of brigadier-general, he succeeded General Anderson in the department of Ohio, from which he was removed for declaring that it would require 200,000 men to hold Kentucky. He distinguished himself at the battle of Shiloh, and as major-general in the siege of Vicksburg.

Raised to an independent command, he marched across the state of Mississippi, and after the defeat of General Rosencranz, took command of the army in Geogia, forced General Hood to evacuate Atlanta, and then marched across the entire state, capturing Savannah and Charleston; from which point he moved north, capturing the most important Confederate positions, and by cutting off the resources of Gen. Lee, compelled the evacuation of Richmond, and the surrender of General Lee to General Grant, April 9, 1865. The surrender of the army of General Johnstone to General S. in North Carolina a few days later, and that of General Kirby Smith, west of the Mississippi, closed the war. No northern general has acquired greater popularlty than Sherman. He divides with Lee and Stonewall Jackson the admiration of impartial foreigners. S. was appointed lieutenant-general in 1866; and, in 1869, became commander-in-chief. He has had ample justice done to the daring originality of design, the fertility of resource, brilliant strategy, and untiring energy, that made Grant pronounce him 'the best field-officer the war had produced.' See *Memoirs of Gen. William T. Sherman*, by Himself; published in 1875.

SHERRY. See Wine.

SHE'RWOOD FOREST, a stretch of hilly country in the west of Nottinghamshire, lying between Nottingham and Worksop, and extending about 25 miles from north to south, and 6 to 8 miles from east to west. It was formerly a royal forest, and the traditional scene of many of the exploits of the famous Robin Hood and his followers; but it is now almost wholly disafforested, and is occupied by gentlemen's seats and fine parks. The town of Mansfield, and a number of villages are situated within the ancient bounds. Numerous remains of the old forest are still to be seen. The soil, which is principally a species of quartzose gravel, is in some places fertile, in others almost barren, and on the whole but of moderate quality.

SHE'TLAND, ZETLAND, or anciently HIALTLAND, and likely the Ultima Thule of the Romans, a group of about 100 islands, islets, and rocks, 23 of which are inhabited. They lie between the Atlantic and the North Sea, between lats. 59° 51′ and 60° 50′ N., and between longs. 0° 53′ and 1° 15′ W.; but Fair Isle, which belongs to S., lies to the south, and is about midway between Orkney and Shetland. The group is about 25 leagues north-east of Orkney, and 44 west of Norway. Area, 325 square miles. There are three chief islands, the largest or mainland, 60 miles long by 3 to 10 broad; Yell, 20 by 6 miles; and Unst, 11 by 6 miles. Pop. in 1811, 22,379; and in 1871, 31,608; 1881, 29,709, and 5444 inhabited houses. In 1871, 67 per cent. of the children between the ages of five and thirteen were receiving education. In 1869, only 4·7 per cent. of the births were illegitimate. Lerwick, 272 miles north of Edinburgh, and 95 north of Wick, is the only town in S., and has a custom-house, law courts, and other public offices, and about seventy shops. Its pop. in 1881 was 3854. It has a fine natural harbor, and has steam communication with Granton bi-weekly in summer, and weekly in winter, for passengers, mails, and a large part of the exports from and imports into Shetland. Fort Charlotte, now used as a prison, court-house, &c., is at the north end of the town, and adds to its picturesqueness. Lerwick has two hotels, two licensed public-houses, and several lodging-houses. The chief imports are oatmeal, flour, tea, tobacco, spirits, sugar, cottons, woollens, timber (chiefly from Norway), tar, salt, &c. From £15,000 to £20,000 worth of breadstuff is imported annually to supply the deficiency of native grain. All classes consume much tea. No wood grows in the country. In 1880, 268 vessels, of 44,582 tons, entered, and 220, of 39,327 tons, cleared the port of Lerwick. Scalloway and Hillswick are the largest villages. The chief exports are dried salted fish, about 3000 tons annually, about a half to Spain; herrings, 4000 to 10,000 barrels in the year; about 2100 cattle and 600 ponies yearly; about 12,000 sheep in 1878; eggs, of which 54,000 have left in one steamer; hand-knitted woollens of great beauty and fineness of workmanship; fish oil; chromate of iron from Unst; copper ore from Sandlodge; iron pyrites formerly from Fitful when sulphur was dear. The exports exceed in value £100,000 annually.

Fishing for cod, ling, herring, is the chief industry, but each fisherman has usually a small farm, at £4 or £5 yearly rent, and mostly worked by the females of his family. In 1876 S. had 614 fishing-boats, with 2772 fishermen and boys. Almost all the small tenants practice spade cultivation. Seals and bottle-nosed whales are often caught. Nearly every house has a quern or hand-mill, and every township has one or more of the old Norse water-mills. The spinning-wheel is common, but the spindle is still in use in some parts. Carts are rare, and in many districts unknown. The sheep and ponies run at large on the Scatfield or Common, and have registered marks; but many large tracts have been enclosed and drained, and now rear first-class Cheviot and black-faced sheep. The *rivlin*, a sandal of untanned leather, is still worn. Some lands are still held runrig, and some islanders on the west still hold their stock as steel-bow. In certain districts, till a very late period, the poor, by the Norse law, went from house to house, and stayed a longer or shorter period in each, according to the size of the farm. The S. dialect is a soft and pleasant English, but contains many peculiar Norse words. Many of the people still eat their fish wind-dried and slightly tainted. Young men from S. are employed as sailors in the Peterhead and Dundee whalers, or at some of the large shipping ports of the kingdom. They are intelligent, sober, and sedate, and are much liked as seamen. S. is still subjected to the *truck* or barter system in local commercial transactions.

S. had a parliamentary constituency of 393 in 1881—1882, and with Orkney forms a county, which sends one member to parliament. In 1881, S. had 5244 horses, 19,117 cattle, 72,156 sheep, and 3789 pigs; 10,774 acres in oats and barley, the only grain crops; and 763 acres in turnips. The native cattle, sheep, and horses (shelties or ponies) are small. The valued rent in 1881—1882 was £40,560. Free landed property is termed udal, and the pro-

prietor an udaller. S. has 14 civil parishes, with 23 Established churches, and 9 Free.

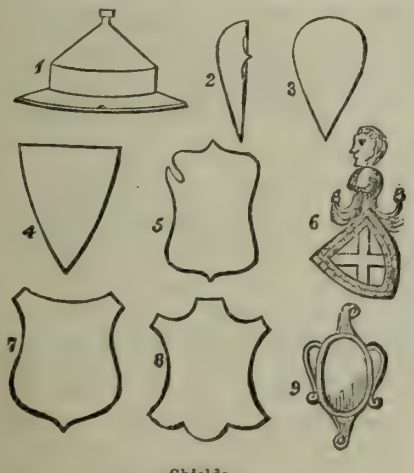
The surface is rugged and wild, and often sterile. The coasts are abrupt, and cut with deep bays or voes, and caves. The rocks are mainly gneiss, clayslate, sandstone, granite, sienite, micaslate, serpentine, and diallage. The highest hills are Ronas, 1500 feet, and one of five in Foula, 1400. The coast-cliff scenery is very fine, and none in Scotland surpasses that about Papa Stour. The climate is moist and variable. South-west, south, and north winds prevail. The mean temperature for the year is 45°, for January 39°, and for July 53°, winter being warmer, and summer cooler than in the south of Scotland. The mean annual rainfall at Bressay is 38 inches, and at East Yell, 50. The tide flows an hour earlier on the west than on the east side of Shetland. The prevailing diseases are dyspepsia, rheumatism, and catarrh. Infant mortality is not high. Idiotcy and imbecility are frequent. Fair hair and blue eyes are very common.

Though we know little or nothing of the original inhabitants of S., the physiognomy, character, and language of the present point to a Norse or Scandinavian descent. In Unst, &c., have been found cairns over long and short stone coffins, with skeletons, clay urns, weapons, and stone vessels. Tumuli and burned stones and earth are frequent, and contain remains of rude buildings and stone implements. Circular strongholds of unhewn stone, called burghs or 'broughs,' are very numerous, generally on a cliff or headland, but also on artificial islands in fresh-water lochs. Mousa Isle has the most perfect 'brough' known. In Sandsting occur very rude underground houses, with the rudest stone implements. In Bressay was found a stone of the Christian period, with an Ogham inscription. Monoliths are rather frequent. Stone circles are rare, and never large.

SHI'BBOLETH (Heb. ear of corn, or stream), the test-word used by the Gileadites, under Jephthah, after their victory over the Ephraimites, recorded in Judges xii. 6. It appears that the latter could not pronounce the *sh*, and, by saying sibboleth, betrayed themselves, and were slaughtered mercilessly. It may be noticed that all those Hebrew names in the Old Testament, which commence with the *sh*, have now, through the inability of the Septuagint to render this sound in Greek, become familiar to us through the versions that flowed from it, as beginning with the simple *s*, e. g., Sem, Simon, Samaria, Solomon, Saul, &c. The word Shibboleth is used in modern languages in the sense indicated: viz. a test of speech and manners of a certain party or class of society.

SHIEL, Loch, in the west of Scotland, forms part of the boundary between the counties of Argyle and Inverness, separating the district of Moidart on the north from those of Sunart and Ardgower on the south. The head of the loch is about 16 miles west of Fort-William. It is 15 miles long, and about one mile broad, and communicates with the sea by Shiel Water and Loch Moidart.

SHIELD, a piece of defensive armor, borne on the left arm, to ward off the strokes of the sword and of missiles. It has been constantly used from ancient times through the middle ages, till the invention of firearms rendered it useless. The large shield worn by the Greeks and Romans (Gr. *aspis*, Lat. *clipeus*) was cir-



Shields.

cular, and often ornamented with devices. Another form of shield (Lat. *scutum*) was used by the Roman heavy-armed infantry, square, but bent to encircle the body. The early shield or knightly escutcheon of the middle ages was circular in outline, and convex, with a boss in the center; the body generally of wood, and the rim of metal (No. 1).

In the 11th c., a form came into use which has been compared to a boy's kite (No. 2), and is said, with some probability, to have been brought by the Normans from Sicily. It was on shields of this shape that armorial designs were first represented. These shields were in reality curved like the Roman *scutum;* but after heraldry began to be systematized, we generally find them represented on seals, monuments, &c., as flattened, in order to let the whole armorial design be seen. In the 13th c., this long and tapering form began to give place to a pear-shape (No. 3), and a triangular or heater-shape (No. 4). During the 14th c., these new forms became more generally prevalent, and the heater-shape, which was perhaps most frequently represented on armorial seals, began to approach more to an inverted equilateral arch. The same variety of forms, with some modifications, continued during the 15th c., a tendency appearing in all representations of the heater-shaped shield to give it more breadth below. A notch was often taken out in the dexter chief for the reception of the lance, in which case the shield was said to be *à bouche* (No. 5). Subsequent to the middle of the 14th c., when the shield came to be depicted as surmounted by the helmet and crest, the shield is often represented *couché*, that is, pendent from the corner (No. 6), an arrangement said to have originated in the practice of competitors hanging up their shields prior to a tournament, where, according to De la Colombière, if they were to fight on horseback, they suspended it by the sinister chief, and if on foot, by the dexter chief. A square shield denoted a knight-banneret. Shields of arms were often represented as suspended from the *guige*, or shield-belt, which was worn by the knights to sustain the shield, and to secure it to their persons.

After the introduction of firearms made shields no longer a part of the warrior's actual equipment, the form of the shields on which armorial bearings were depicted, on seals, monuments, brasses, &c., varied greatly in form, and generally speaking, became gradually more tasteless, fanciful, and unmeaning (Nos. 7, 8, 9). A tendency has, however, been shown in recent heraldry to recur to the artistic forms prevalent in the 14th and 15th centuries.

In early times, shields of the form which generally prevailed at the period, were exhibited on the seals and monuments of ladies; but about the 15th c., the practice began, which afterwards became usual, of unmarried ladies and widows (the sovereign excepted) bearing their arms on a lozenge instead of a shield.

The heraldic insignia of towns, corporations, &c., as well as individuals, are placed on shields. The bearing of Merchants' Marks (q. v.) in a shield was prohibited by the heralds of the 16th c. under severe penalties, and yet not a few instances are to be found on monumental brasses of these devices being placed on shields.

SHIELDS, North, a seaport and market-town of Northumberland, in the parish of Tynemouth, on the north bank of the Tyne, and at the mouth of that river, opposite South Shields, and eight miles east-north-east of Newcastle. It stretches more than a mile along the river-bank, and is rapidly extending westward, owing to its rising trade and manufactures. There are numerous collieries in the vicinity, and the Northumberland Docks, which are within the borough, export more than a million tons a year. The harbor is bordered with quays; and the quays of North and South Shields (which are, however, separate ports) are spacious enough to accommodate 2000 vessels of 500 tons each. North and South Shields possess together upwards of 200,000 tons of shipping. The building of wood and iron vessels, and tug-steamers, the manufacture of anchors, chain-cables, ropes, blocks, masts, and other articles of ship-furniture, are the principal branches of industry. North S. has a free library, sailor's home, and theater. In conjunction with Tynemouth (q. v.), and three smaller townships, it forms a municipal and parliamentary borough, named after Tynemouth, and sends one member to parliament. Pop. of parl. and mun. borough of Tynemouth (1871), 38,941, of which total, however, only 8619 belonged to North Shields; (1881) 43,863.

SHIELDS, South, a custom-house port, municipal and parliamentary borough and market-town of Durham, on the south bank of the Tyne, and at the mouth of that river, 9 miles east-north-east of Newcastle by river and railway. The town stretches for two miles along the side of Shields harbor, which is lined with numerous dockyards and manufactories. The Tyne Dock, containing 50 acres of water space, in which upwards of a million tons of coals are annually shipped, and a large import trade is carried on, is within the borough. The market-place is a spacious square in the center of the town, near which is the large church of St. Hilda. The town, with North Shields, is one of the chief ports in the kingdom for the building of iron ships, iron screw-steamers, and tug-steamers. There are large alkali, bottle, and glass works, and every kind of manufacture connected with shipping. A steam-ferry for passengers and carriages plies day and night between the two towns, one on the north, and the other on the south side of the entrance to the Tyne. Shields bar has been

removed by dredging, in order, with the piers, to form a harbor of refuge. The sea-coast, in the neighborhood, is interesting from the rocks and caves. The life-boat is a South S. invention. South S. sends one member to parliament. South S. possesses a large public library, with news-room, and large hall for public meetings. There is an extensive colliery, that of St. Hilda's; a school board; and Tyne Pilotage Board. The Nautical College, founded on a bequest of £30,000, was opened in 1869; it includes a museum and observatory. Pop. (1861) 35,239; (1871) 45,336; (1881) 56,922.

SHI'ITES ('sectaries,' from the Arab. *Shiah, Shiat*, a party, a faction), the name given to a Mohammedan sect by the 'Sunnites' (q. v.), or orthodox Moslems. The S. called themselves 'followers of Ali,' and have special observances, ceremonies, and rites, as well as particular dogmas of their own. The principal difference between the two consists in the belief of the S. that the Imamat, or supreme rule, both spiritual and secular, over all Mohammedans, was originally vested in Ali Ibn Abi Taleb, and has been inherited by his descendants, to whom it legitimately now belongs. The Persians are S.; the Turks, on the other hand, are Sunnites; and this division between the two nations dates chiefly from the califate of Mothi Lilla, the Abasside, in 363 H., when political dissensions, which ended in the destruction of Bagdad and the loss of the califate of the Moslems, assumed the character of a religious war. The S. themselves never assume that (derogatory) name, but call themselves *Al-Adeliat*, 'Sect of the Just Ones.' They are subdivided again into five sects, to one of which, that of Haidar, the Persians belong: the present dynasty of Persia deriving its descent from Haidar, a descendant of Ali. Ali himself is, by some of them, endowed with more than human attributes.—The S. believe in metempsychosis and the descent of God upon His creatures, inasmuch as He, omnipresent, sometimes appears in some individual person, such as their Imams. Their five subdivisions they liken unto five trees, with seventy branches; for their minor divisions of opinions, on matters of comparatively unimportant points of dogma, are endless. Yet, in this they all agree, that they consider the califs Abu Bekr, Omar, and Othman, who are regarded with the highest reverence by the orthodox Sunnites, as unrighteous pretenders, and usurpers of the sovereign power, which properly ought to have gone to Ali direct from the Prophet. For the same reason, they abominate the memory of the Ommayad califs, who executed Husain, a son of Ali, and they still mourn his death at its anniversary. They likewise reject the Abasside califs, notwithstanding their descent from Mohammed, because they did not belong to Ali's line.

SHIKARPU'R, the most important trading-town, and probably the most populous town, in Sinde, stands about 20 miles west of the Indus, half way between Multan and Kûrrachi. The district in which it stands is so low and level, that, by means of canals, which are supplied from the Indus, it is flooded every season. Its climate, notwithstanding, is said to be not unhealthy. The inundated quarters are extremely fertile and produce great crops. Groves, orchards, and fruit-gardens surround the town; sugar-cane is largely grown. S. is situated on one of the great routes by the Bolan Pass from Sinde to Afghanistan, and the transit-trade to that country and to Khorassan is important. The bankers and financiers of S. are known and trusted from Astrakhan to Calcutta. S. is the chief town of the district of the same name, which has an area of 8813 sq. m., and 776,227 inhabitants. Pop. of the town (1872) 38,107, about 20,000 of whom are Hindus, and the rest chiefly Mohammedans.

SHI'LKA. See AMOOR.

SHILLING, the name of a money in use throughout many European states, partly as a coin, and partly as a money of account. In all probability, the name, as well as the thing itself, is derived from the Roman *solidus*, which, with other remains of Roman institutions, was adopted by the Franks and other Germanic nations. See PENNY, SOLIDUS. Others give more fanciful derivations, as from *schellen*, to ring, on account of the particularly clear ring of the coin, and from St. Kilian, whose effigy was stamped on the shillings of Würzburg. The *Solidus-shilling* of the middle ages has suffered various degrees of diminution in the different countries. Thus, the English silver shilling is $\frac{1}{20}$th of a pound sterling; the Danish copper one is $\frac{1}{96}$th of a ryksdaler, and = $\frac{1}{4}d.$ sterling; and the Swedish shilling is $\frac{1}{48}$th of a ryks-daler, = $\frac{1}{8}d.$ sterling. In Mecklenburg, Slesvig-Holstein, Hamburg, and Lübeck, the shilling is used as a fractional money of account (the $\frac{1}{10}$th of a mark, $\frac{1}{48}$th of a thaler), and as small silver change (each coin being a shade less in value than 1*d.* sterling). The French *sou* is another representative of the solidus. See POUND MINT.

SHIN, LOCH, in the south of Sutherlandshire, measures 18 m. by 1 m. The Shin Water, a famous trout-stream, carries the waters of the loch into Oikell Water. Loch S. abounds in trout and salmon.

SHINGLES, flat pieces of wood used in roofing like slates or tiles. Such roofs are much used in newly-settled countries where timber is plentiful. The wood is chosen from among the kinds which split readily and straightly, and is usually some kind of fir. It is cut into blocks, the longitudinal faces of which are of the size intended for the shingles, which are then regularly split off in thicknesses of about a quarter of an inch.

SHINGLES (probably derived from Lat. *cingulum*, a belt) is the popular name for the variety of *Herpes* (q. v.) which is known as *H. zoster*.

SHINTOISM. See JAPAN.

SHIP (from the root *skap-*, to scoop, dig) is a term applied with great vagueness to all large vessels; while under *shipping* would be included vessels of all sizes, excepting boats without decks. Among seamen, the expression is said to be limited to vessels carrying three masts, with a royal-mast surmounting each; but the development of steam-navigation, in which the largest vessels have sometimes only a schooner rig, must have gone far towards obliterating this distinction.

SHIP-BROKER, INSURANCE BROKER. A ship-broker is a person employed in the buying and selling and freighting of ships. His duties include adjusting the terms of charter-parties and bills of lading, settling with the master for his salary, collecting freights on goods brought into port, arranging with passengers for the terms of their passage, and generally managing all business transactions occurring between shipowners and the shippers or consignees of goods. The charges made by ship-brokers are generally about two per cent. on their gross receipts. Ship-brokers have been ruled not to be within the acts for the regulation and admission of brokers.

The business of an *insurance broker* is usually combined with that of a ship-broker. Marine insurance is in Great Britain to a large extent transacted by brokers. Those who insure are in most cases capitalists, who are known to the broker as persons prepared to undergo any risks which he recommends to them. The broker, who has a list of persons ready at a moment's notice to underwrite a policy, is the mutual agent for both parties. He procures the subscriptions of the underwriters, arranging with them the rate of premium and conditions of the risk, receiving from them the amount of their respective subscriptions, in the event of loss; and, when such loss is partial, arranging the proportion to be recovered from the different underwriters. An insurance broker charges as profit five per cent. on the premium, and one-half per cent. deducted from all claims recovered from the underwriters. An insurance broker is personally liable to the underwriters for the amount of the premium, but incurs no liability to make good the amount insured to the owner of the ship and goods, who, in case of loss, must look to the underwriter alone for indemnification.

SHIP-BUILDING. See NAVIGATION; NAVIES, ANCIENT AND MODERN; and NAVY, BRITISH. From crossing a river or lake on a floating log, or on two or more logs fastened together raft-wise, the first steps towards ship-building were probably Canoes (q. v.), and Coracles (q. v.). The earliest Egyptian drawings show boats constructed of sawn planks, and having sails as well as numerous oars. So far as can be learned from ancient sculptures, the galleys of the Mediterranean at the dawn of civilization appear to have been open, at least in the middle portion; to have been built with keel, ribs, and planking, and to have been strengthened cross-wise by the numerous benches on which the rowers sat. Ships continued, however, to be generally of small draught, for they were beached every winter; and Cæsar mentions, as a noteworthy circumstance, that some of the long ships with which he invaded Britain could only approach the shore to such a point that the soldiers in disembarking were breast-high in the water. The Romans built their vessels of pine, cedar, and other light woods; but their ships of war were of oak at the bows, clamped strongly with iron or brass, for use as rams—a custom now curiously revived after 2000 years of disuse. According to Cæsar, the Veneti first built entirely of oak. The speedy oxidation of iron bolts and fastenings led to their supersession by copper and brass about the time of Nero. Before this time, the planks had been calked with flax, and the seams had been pitched. There is evidence to show that in Trajan's reign sheathing of lead fastened on with copper nails had been used as a protection for the timbers from the devastating insects of the Mediterranean. With the decline of Roman greatness came a new era for ship-building. The hardy Norsemen had chopping seas and Atlantic swells to fight with; their ships differed much from the stately galleys and quinqueremes of the empire. Far smaller, they were built more stoutly, with bluff bows, and a lug-sail which could be braced well up to the wind. The Norse ships must have been of considerable power, for there is good evidence that they had visited the coasts of the New World at an early period.

We have, however, very little knowledge of the construction of these vessels, except that they had high prows and sterns to resist the waves, and that they were calculated for sailing in opposition to the galleys, which were for rowing. The introduction of galleys by Alfred, pulled by 40 and 60 oars, and twice as long, deep, nimble, and steady as the Danish ships, kept the latter in check; but it also checked the development of ocean-navigation, for the galleys were only fit for shore-service. The ships gradually increased in size. Hardicanute had a galley pulled by 80 oars; and contemporaneously, the Venetians are said to have built ships of 1200 to 2000 tons. William invaded England in miserably small sailing vessels; but large—indeed very large—vessels appear to have existed in the time of Richard I. John systematized ship-building by establishing a royal dockyard at Portsmouth. Large ships constructed for sailing only seem to have come into general use, together with the mariner's compass, in the beginning of the 14th century. One hundred and fifty years later, the addition of the bowsprit added much to the sailing-powers of vessels.

In Ellis's Collection of Letters there is one, dated 1419, from John Alcêtre to King Henry V., concerning a ship building at Bayonne for that monarch. This letter is curious, as showing how many of the present terms then existed, and also that the 'Kynges schyppes' were of considerable dimensions (e. g., 'the stemme is in hithe 96 fete; and the post 48 fete; and the kele ys yn leynthe 112 fete.') Before this period, ships had been built strong enough to encounter ice in the whale-fishery. From this period the history of ship-building is resolved into the history of individual parts, for the main principles of wooden ships were already established. In Henry VII.'s reign, the cumbrous fourth mast began to be dispensed with; in that of his successors, shifting top-masts came into fashion, the lofty stems and sterns (which must have precluded sailing on a wind) fell gradually into disuse. Port-holes were invented at least as early as 1500. In 1567, there were cutter-rigged vessels in the British seas. In the century ensuing, naval architecture was much improved by Mr. Phineas Pett, his son Peter, and by Sir Anthony Deane; but the best naval architects were not in England. Within the present century, the introduction of steam has led to the building of ships with finer lines, both for bow and stern. About 1836, iron was introduced as a material for ship-building, and has now (1878) so far superseded wood, that, taking steamers and sailing ships together, 10 iron vessels are built for 1 wooden one.

Adverting now to the actual art and practice of ship-building, the subject is divisible into two distinct portions—the theoretical, known as *Naval Architecture;* and the practical, called *Ship-building.* The naval architect designs the form of a ship with reference to the objects intended in her construction, to the speed required, powers of stowage, &c.; while the ship-builder works from his drawings, and gives practical effect to the theoretical design.

Naval architecture on a theoretic basis is of recent date, for, as in all cases, practical efforts, more or less in the dark, have preceded by many ages the theorems of the man of science; nor is it at present by any means an exact science: some most successful ships have been but happy experiments. Our present knowledge of naval architecture we owe mostly to the researches of such men as the late Professor Rankine, Mr. Scott Russell, Mr. Froude, and others. All ships have to possess certain qualities, the principal of which are buoyancy, stability, handiness, and speed; but it is not possible for any ship to possess at the same time the maximum of all these, as to some extent they neutralize each other. The skill of the naval architect is shown in duly proportioning them to one another, ascertaining which are the more important in each particular case, and providing these without unduly impairing the others. In some vessels, it is essential that the greatest possible speed should be attained; while, as they are to work only in smooth water, their degree of stability (or freedom from excessive rolling, and tendency to right themselves when heeled over by a wave) is only secondary. In others, which have to weather long-continued storms in mid-ocean, speed may have to be sacrificed to attain greater steadiness. In sailing-vessels, where the means of propulsion is not under control of the crew as in steamers, handiness—the property of answering quickly to their helms, and of readily performing various manœuvres (such as tacking) under all conditions of weather—is often the quality to which most attention has to be paid. Along with all these things, the ship has to be made so as to have the largest possible amount of cargo or passenger space consistent with the proper degree of buoyancy. The degree in which a ship possesses the various qualities named depends chiefly upon her external form and dimensions, about which the following general statements may be given:

An increase of length gives an increase of displacement of water, and therefore of carrying-power; if this be not desired, it allows of finer lines forward and aft, and consequently greater speed. It also increases the resistance to lee-way. The greater friction of the water on the longer sides does not appear to be material. Against the increase is to be set a diminished power of turning, tacking, and wearing. It also involves a more careful balancing of weights in the fore and after portions of the ship, for the moment of inertia of a small weight may become large in a long vessel, from being such weight multiplied into the square of its distance from the ship's center of gravity.

The increase of breadth gives greater stability to the ship, and, by allowing of more sail, indirectly greater speed; but directly, it increases the resistance to the water. Of course, greater breadth enables greater bulk to be carried. Depth is a question dependent on the seas to be navigated, the object for which the ship is intended, and many other reasons. It is to be borne always in mind that the consumption of stores on a long voyage will change the draught of a ship considerably. Practice has proved unequivocally that ships sail better for drawing more water aft than forward.

Passing now to the actual designing of vessels: the architect works on paper only; he has therefore to show on a flat surface, for the builder's guidance, the exact position, curvature, and relief of every line and point in his proposed structure. He accordingly draws three plans, on each of which every point of the ship is traceable: the *sheer-plan*, showing all lines of length and height; the *half-breadth plan*, lines of length and breadth; and the *body-plan*, which shows breadth and height. From these combinations, the exact position of every point is determinable.

Figures 1 to 3 show those plans, called *construction drawings*, on the same scale for the *Great Eastern* steamship. The sheer-plan represents, in its outside line, a vertical plane through the keel. The dotted lines, 1, 2, 3, are the edges of supposed horizontal planes drawn at various heights. The curved lines, I, II, III, are the edges, as they would appear on the outer covering of the ship, of vertical planes drawn parallel to the central plane through the keel. The uprights, A, B, &c., A_1, B_1, &c., are the edges of supposed planes drawn at given distances from the line of greatest breadth X, at right angles to the plane through the keel.

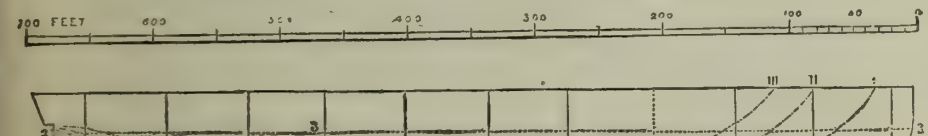


Fig. 1.—*Great Eastern*—Sheer Plan.

The half-breadth plan represents one half of the ship's upper deck, as regards the black outer line; the horizontal, vertical, and cross sections of the sheer-plan appearing again under different conditions. The vertical longitudinal sections become straight lines parallel to the keel; the horizontal sections appear as curves taken at different heights on the vessel's sides. The body-plan is the ship looked at end-on; the outer line being her cross section at the line of greatest breadth, and the horizontal and vertical sectional lines appearing at right angles to each other. The lines on the left side correspond to the cross sections of the after-body (that is, the portion of the ship nearer the stern than the line of greatest width), and show the curvature of the ship's sides towards the stern; while in a similar manner those on the right side show the curvature up to the bow. Of course, in working-drawings from which ships are to be actually built, the scale employed would be very large; and instead of three or four sectional lines in each direction, a great number would be inserted for the guidance of the builder. With these three plans in hand, the workman has the exact position of every point in the ship's exterior coating exactly defined. Even the un-

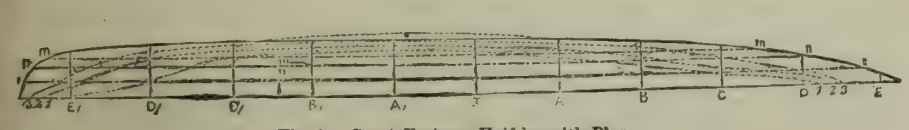

Fig. 2.—*Great Eastern*—Half-breadth Plan.

professional observer need not strain his imagination greatly to clothe these flat plans with their dimensions of length, breadth, and depth, and to conjure up before his eyes the precise form of the goodly ship represented.

Further, to illustrate the lines of different classes of ships, figs. 4 and 5 show the half-body plans of well-known vessels, the clipper *Lord of the Isles*, and the yacht *America*.

With the completion of the construction drawings the work of the naval architect ceases, but in most cases the two professions of naval architect and shipbuilder are combined in one firm, if not in one man. It is then to be decided of what material the ship shall be constructed. The choice lies between iron, steel, wood, and a combination of wood and iron. Of the many woods employed, oak, teak, and fir are those most commonly used. The building of a wooden and of an iron ship are quite distinct operations, the requisite strength being obtained in a different manner in each case. It is necessary, therefore to consider separately the principles of wooden ship-building and iron ship-building; and as the older and most time-honored process, we will first deal with the art of the shipwright who forms the vessel of timber.

Fig 3.—*Great Eastern*—Body Plan.

In addition to the construction drawings which we have described, it is usual also to construct a small wooden model of the ship—upon a scale very often of ¼ inch to the foot—which shows the designer what his ship is going to look like better than the flat paper can do. This model is made of a number of horizontal layers of wood, and upon it the whole arrangement of the plating of the ship is marked, with the position of all the joints, &c.

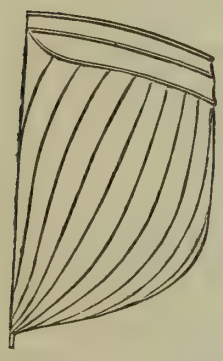

Fig. 4.—Clipper—*Lord of the Isles.*

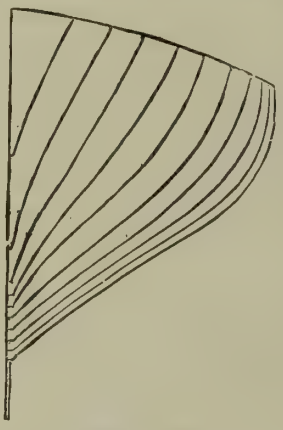

Fig. 5.—Yacht—*America.*

Wooden Ship-building.—The first process is to develop, or 'lay off,' on the *mould-loft floor*, certain full-size working sections of the required ship. These are taken from the construction drawings and the model, and are built up of planks. The combinations of these pieces of plank show the shape in which the several timbers will have to be cut, to impart the necessary curvature and strength.

The next step in actual construction is to prepare the slipway, by raising a number of strong blocks of timber a short distance apart, on which the keel shall rest, and which shall sustain the entire ship when built. These blocks are composed of several pieces, and it is of the utmost importance that their upper surfaces be in an exact line. That line is made at an inclination of ⅝ths of an inch to a foot; and the keel of the ship, and the ship itself, have consequently that slope to the horizon while building. This inclination is for the facility it affords in launching the completed vessel. On the blocks is laid the keel, which may be called the back-bone, and is certainly by far the most important timber in the ship. From it start the ribs, the stem, and the stern-post; so that any serious accident happening to the keel, involves the breaking up of the whole structure. It is therefore made of great strength, being, in a first-rate, no less than 20 inches square. The material is usually elm, on account of its toughness, its non-liability to split, and the fact that immersion in sea-water preserves it. The pieces of which it is composed are united by the strongest kind of scarph joint (see CARPENTRY).

What the keel is to the bottom, the stem and stern-post are to the bow and stern of the ship, forming the keys from which the ends of the planking (technically called the 'butts') and all longitudinal supports start. Each is, of necessity, of great strength, and they rise from the respective extremities of the keel. The *stern-post* has to bear the rudder, and is usually made, when possible, of one piece of timber; it is united to the keel by a mortise and tenon joint. In screw-steamers, there is a second stern-post, forming the forward support for the screw.

The extreme outlines of the ship being now established, the builder proceeds with the timbers to form the bottom and sides, which together constitute the *frame*, corresponding to the ribs in an animal. The ribs form the sides of the ship, and are placed at from 2 feet 6 inches to 3 feet 9 inches from center to center. Up to the water-line, the spaces between them are filled in solid with timbers of equal thickness. For this purpose, in the midship-body the keel is crossed at right angles or nearly so, by certain timbers which form the *floor*. The keel is let about three-fourths of an inch into a groove running along the bottom of the floor, while above the floor, the *keelson* is a massive timber, parallel to the keel. The keel and keelson are bolted firmly together by long copper bolts, which pass through the timbers of the floor, and completely fix the latter. As an additional strengthening to the frame in large vessels, *side* or *sister keelsons* are bolted on to the floor or futtocks, a short distance on each side of the principal keelson. Fig. 6 is a cross section of a three-decked wooden vessel, showing a complete rib, with the principal parts as they are commonly arranged amidships. Near the ends of the ship, the frames no longer stand at right angles to the keel, but are necessarily bent or canted round.

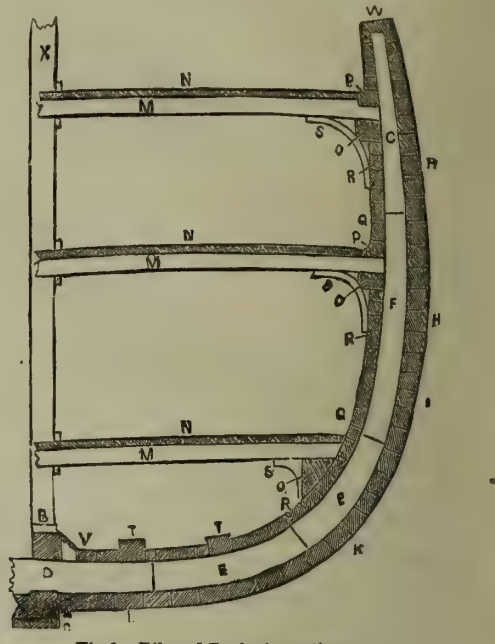

Fig 6.—Rib and Decks in section:
A, keel; B, keelson; C, false keel; D, floor; EE, futtocks; F, top-timber; G, lengthening piece; HH, wales; I, diminishing planks; K, bottom planks; L, garboard strakes; M, beam; N, deck; O, shelf; P, waterway; Q, spirketting; R, clamps; S, knees; T, side-keelsons; V, limber strakes; W, rough-tree rail; X, mast.

After the main skeleton, as it were, of the ship is built, the skin is the only thing remaining to complete its exterior. This is represented by thick wooden planking, fastened on to the ribs, the lowest layer pressing into the rabbet of the keel, and the highest reaching to the uppermost bulwark. The thickest planking is at the bends or wales, marked H in fig. 6, where it varies from 4½-inch in small vessels to 10-inch in ships of the first class. Every complete line of planking from stem to stern is styled a *strake*. Oak and fir are the woods mostly used for the skin, and elm for the planks nearest the keel. The planks are generally fastened to the ribs by copper bolts, but wooden treenails are frequently employed, as less in weight than copper, and less liable to split the wood. The comparative utility of wood and copper fastenings for the strakes is still a disputed point.

In a well-constructed ship the filling in of the timbers to a level above the water-line should be so accurately formed that she would float without her planking; but when the latter has been well calked, it is certain that it adds greatly to the dryness of the ship, while it aids materially in binding her several parts together.

At frequent intervals across the ship, and at the heights of the several decks, are inserted the *beams*, which are solid masses of timber, either in one piece or scarphed. These prevent the ship from collapsing, and at the same time support the decks. The beams and decks are shown at M and N respectively in fig. 6. The beams are always made convex upwards, principally for the sake of preventing water lodging on the decks. When the beams are

well established, the hatchways and mast-holes are traced out. This done, the deck is laid down of straight-grained hard wood, and the planks are calked and pitched between, until the deck or platform becomes perfectly water-tight.

Along the inside of the bottom are laid the *sister keelsons* or *side keelsons*, if the ship be large, and all spaces are filled up with planking, except the width of one plank next the keelson on each side, which is left for a drain to carry all refuse-water to the foot of the pumps.

Iron Ship-building.—Iron affords in many respects a better material for ships than wood. In the first place the same strength may be obtained with less weight; secondly, iron plates can be bent to any curve, so that the combinations necessary for strength in wooden vessels can be avoided. The laying off the lines of the

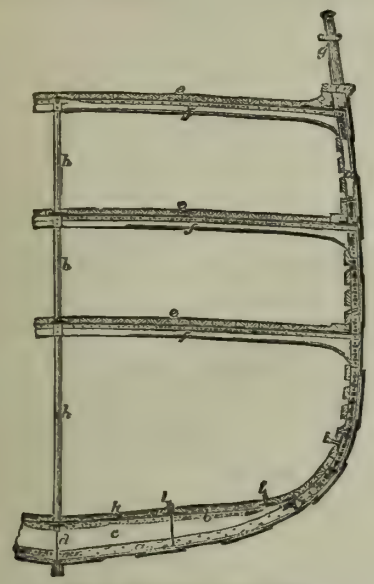

Fig. 7.—Section of Iron Ship:
a, frames; *b*, reverse angle-irons; *c*, floors; *d*, keelson plate; *e*, *e*, decks; *f*, *f*, deck beams; *g*, bulwarks; *h*, *h*, stanchions; *i*, *i*, bilge keelsons; *k*, ceiling.

vessel full size upon the mould-loft floor is the first process in iron as in wooden ship-building. Rough wooden templates are here made of the cross-sections of the ship, one template to every cross section.

The slip-way is prepared in much the same way as in the case of a wooden ship. The keel is generally of flat bar-iron—sometimes in several thicknesses—the different lengths being scarphed at the ends and riveted together, or sometimes welded. In the cross-section of a 2000-ton iron vessel given in fig. 7, the keel is in five thicknesses; in the middle a center-plate which is carried upwards through the floors, and forms a keelson; on either side of this a thick bar, and outside these again the two lowermost plates of the skin bent downwards. The whole five thicknesses are riveted together.

The ribs in an iron ship are called 'frames.' They are always made of angle-iron (*a*, fig. 8), and are placed from 18 inches to 2 feet apart. They are bent, while red-hot upon a large flat cast-iron plate into the proper curve, fixed by the templates already mentioned. The frames, when thus bent to the right shape, are

Fig. 8.

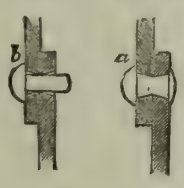

Fig. 9.

set up in place upon the keel. To them are fastened at the bottom the *floors*, which are narrow plates running across the ship; and frequently additional stiffness is gained by running 'reverse' angle-irons along the top of the floors, throughout at least a considerable portion of the ship's length. The beams which support the deck, and which are convex upwards as in wooden ships, are made of such a section as is shown in *b* or *c*, fig. 8.

After the frames, floors, and beams are in place, the plating commences, each particular plate being of a size and shape exactly as determined by the model. The lowest plates of all are called the 'garboard strake,' and are usually bent downwards and riveted to the sides of the keel, as in fig. 7. The thickness of the plates gradually diminishes upwards, till the 'sheer strake'—the strake at the level of the main-deck—is reached, and this is always made very strong. The deck beams are further secured and stiffened by longitudinal and diagonal plates called 'stringers.' All the iron-work of a ship is fastened together by rivets. Holes are first punched or drilled in the plates and angle-irons—in most cases before they are put together. The holes having been made exactly to overlap, a red-hot rivet is inserted through them, as in *b*, fig. 9. A man, called a 'holder-up,' holds the head of the rivet forcibly in its place with an iron tool, while two riveters on the other side of the plate strike its end rapidly with their hammers, until it is all hammered down as at *a*. The contraction of the rivet when it cools causes it to hold the two plates still more tightly together. Iron ships are always divided into a number of compartments by transverse partitions called 'bulk-heads.' These partitions can easily be made water-tight, and then afford great additional security to the vessel, as, in the event of a leak occurring, it will often be possible to confine the water to the space between two bulkheads, and there will be sufficient buoyancy in the other compartments to keep the vessel afloat. The bulkheads are fitted with water-tight doors, and besides being a source of safety, they are also the cause of great additional transverse strength.

By the time that the external plating of the ship is finished, and the beams and bulkheads all in their places, she is ready for launching; much, however, still remains to be done to her. Most frequently, the greater part of the decks has to be laid, and the whole of the cabin fittings to be put up; the rudder and steering gear have to be fitted; the wooden 'ceiling' (which lines the hold) to be put in; the masts have to be set, and all the spars, sails, and rigging put up; and lastly, in a steam-vessel, the engines and boilers have to be placed and properly secured on the seatings provided for them.

Steel has till lately been little used in the construction of ships. As it possesses much greater strength than iron, all the various parts of a steel ship may be made much lighter for the same strains than in an iron one; but there has been a very widespread distrust of it, based on the difficulty of getting really reliable steel plates and bars. But since 1880 the use of steel has been steadily growing in favor. On the Clyde, for example, the tonnage of steel-built vessels in 1879 was only 18,000 tons; in 1880, it was 42,000 tons; in 1881, 66,600 tons; while in 1882, 60 vessels were built of steel, with a tonnage of 108,254 tons.

Ships of Iron and Wood conjointly, or 'composite' vessels. It was at one time thought that various advantages would be obtained by the use both of iron and of wood in the same ship, the frames and beams being made of the former material, and the skin of the latter. Composite vessels were always more used by the French than among ourselves, but although Lloyd's committee have thought this class of vessels of sufficient importance to publish special rules in reference to it, very few composite ships are now constructed. Of above 1000 ships built in a year, not more than a dozen or so are composite; and of the total new tonnage added in a year to the register of British shipping, an extremely small proportion belongs to composite vessels.

In some recent ships of war (e. g., the *Triumph* and *Swiftsure*), the vessels, after being built of iron in the usual way, and heavily armored, have been covered all over with planking, and copper-sheathed. The object of this has been to insure that the ship's bottom shall not be fouled with weeds and barnacles, which so easily happens with iron vessels, as these frigates are intended for very high speeds.

Internal Arrangements of a Ship.—Whether the vessel be of iron or wood, her internal design must follow the purposes for which she may be required. As a general principle, the ship is divided into a greater or less number of platforms, floors, or decks (q. v.), devoted to various purposes. In a ship-of-war a large portion is required for the men, the remainder being occupied by warlike stores, provisions, and coal. In a merchant-vessel, far less space is allotted to the crew, and far more to the cargo. In every ship, a space must be provided for the carriage of provisions and water proportionate to the number of the crew and the intended duration of voyages. A steamer differs from a sailing-vessel in requiring a large compartment amidships to be kept clear for her engines and boilers. In screw-steamers, to the height of the boss of the screw above the keelson, a tunnel, known as the *screw-alley*, has to be kept open for the shaft of the screw from the engine-room to the stern. The heavier portion of a cargo, as coal and water, is carried immediately above the keel, so that the center of gravity may be as low as possible, and for the same reason the engines and boilers are placed as low down as practicable. For various details concerning the formation and arrangement of ships, the reader is referred to detached articles descriptive of the respective portions, as DECKS, MASTS, CAPSTAN, CHAINS, CHANNELS, HOLD, KEEL, SAIL, SHEATHING, &c.

Lloyd's.—In order that a ship may be insured by the underwriters, it has to be inspected and surveyed by one of the survey-

ors of 'Lloyd's.' According to the reports of their surveyors, the committee of Lloyd's Registry classify the vessel, affixing to its name a letter which is intended to be an indication of its qualities. For wooden vessels, these letters (in order of excellence) are A (in black or red), Æ, E, and I; for iron ships or steamers they are $\frac{A}{A}$, $\frac{A}{B}$, and $\frac{A}{C}$. Numbers put before these letters indicate the number of years for which they are to hold that grade; and numbers (1 or 2) put after the letters refer to the completeness of their equipment.

Of late years there has been a decrease in the *number* of sailing-vessels and steamers built, but an increase in the joint *tonnage* (as also in the number of steamers. There was a depression in the ship-building trade between 1874 and 1880; but the tonnage of ships built in 1881 for the foreign trade exceeded that of any previous year by 25,000 tons.

NUMBER AND TONNAGE OF VESSELS, THE BUILDING OF WHICH WAS COMPLETED IN THE YEAR 1875, IN THE UNITED KINGDOM.

SHIP-MONEY, a tax had recourse to in England at various times, but especially in the reign of Charles I., for the equipment of a fleet. In 1007, when the country was threatened by the Danes, a law was made obliging all proprietors of 310 hides of land to equip a vessel for the protection of the coast. Elizabeth, at the time of the threatened Spanish invasion, required the various ports to fit out a certain number of ships at their own charge; and so great anxiety was shown by the public for the national defence, that London and some other ports furnished twice as many vessels as had been demanded. It was in 1626 that Charles first had recourse to an impost of this description, requiring each of the maritime towns, with the assistance of the neighboring counties, to arm a given number of vessels, 20 being required from London. In 1634 the tax was extended over the whole kingdom. A general spirit of resistance was immediately aroused, not so much in consideration of the amount of the tax, as of the objectionable feature that it was imposed by the arbitrary authority of the king alone, which had come to be regarded as an unwarrantable stretch of the royal prerogative. In 1637, the celebrated John Hampden, a gentleman of property in Buckinghamshire, resolved to confront the power of the government by disputing the legality of this exercise of the prerogative, and resolutely refused payment of the impost, an example in which he was followed by nearly the whole county to which he belonged. He was prosecuted in the Exchequer Chamber for non-payment, and his trial was watched with great interest and anxiety by the nation on account of the constitutional point involved in it. The judges, four excepted, pronounced in favor of the crown; but the trial had the effect of thoroughly arousing the public mind to the danger of the imposition of taxes by the royal authority alone. The Long Parliament, shortly after its meeting in 1640, voted ship-money illegal, and the sheriffs and others who had been employed in assessing it or collecting it to be delinquents; and cancelled the sentence against Hampden.

SHIPPING. See Merchant Ship. Act.

SHIP-WORM. See Teredo.

SHIPWRECKS, in ancient times, were deemed the property of the crown, but by a statute of Henry I., the harsh consequences of this law were avoided whenever any person escaped alive out of the ship; and in Henry II.'s charter it was declared that if either man or beast escaped alive, the goods should remain to the owners if claimed within three months; and the courts of law still further refined away all these harsh rules. Many nice distinctions have been made as to what goods constitute wreck, which is distinct from goods floating. See Flotsam. By the Merchant Shipping Act, 1854, which extends to the United Kingdom, the Board of Trade has the superintendence of all matters relating to wreck, and to jetsam, flotsam, and ligan. Receivers of wreck are appointed for various districts, and have power to summon assistance. When wreck is found by any person, he must give notice to the receiver of wrecks, and if nobody claim the property within a year, it is sold, and the proceeds, after paying salvage and other such expenses, are paid into the Exchequer. Persons plundering wreck are guilty of felony, and may be punished with three to fourteen years' penal servitude; and any person exposing false signals to cause wreck, may be sentenced to penal servitude for life.

The number of wrecks, casualties, and collisions from all causes on or near the coasts of the United Kingdom, reported in 1874–5, was 3590; a large increase on previous years, accounted for in great measure by the inclusion of small casualties not previously counted, &c. In the year 1879–80, a much larger number—5204—was reported. Of the casualties of 1874–5, about 1 in 23 resulted in loss of life. It having been found in numerous instances that the direction and force of the wind as given by the masters in their reports differed more or less from the particulars of weather reported to the Meteorological Office during 1872, steps were taken towards making strict inquiry at the moment into all such variations.

The life lost in 1874–5 was distributed as follows: In fishing smacks, 110; in vessels carrying heavy cargoes in bulk, 207; and in other vessels, 609. Three hundred and thirty-eight wrecks and casualties happened in 1874–5 to nearly new ships, 646 to ships from 3 to 7 years of age; 921 to ships from 7 to 14 years old; 1262 to ships from 15 to 30 years old; 567 to ships from 30 to 50 years old; 74 to ships between 50 and 60; 31 to ships between 60 and 70; 18 to ships between 70 and 80; 11 to ships between 80 and 90; 3 to ships between 90 and 100; and 3 to ships over 100 years old. The ages of 385 vessels were unknown. The sum paid by the Board of Trade out of the Mercantile Marine Fund for providing apparatus for saving lives on the coasts of the United Kingdom in 1874–5 was £11,010; the expenditure on this account in the 20 years 1855—1875, was £163,445, besides £1337 paid by the Admiralty on account of life-belts. At the end of June 1875, there were on the coasts of the United Kingdom 277 sets of rockets or mortar apparatus provided by the Board of Trade. The number of life-boats in 1875 was 273, of which 244 belonged to the National Life-boat Institution; and 29 (of which six were subsidized by the Board of Trade) were under other management. 548 stations were supplied with Captain Ward's life-jackets for the use of the coast-guard. The number of Volunteer Life Brigades in 1875 was 5, and the number of Volunteer Life Com-

panies, 1160. The number of lives saved on or near the coasts of the United Kingdom in 1878–9 was 3302—449 being saved by lifeboats; 269 by rocket and mortar apparatus lines, &c.; 228 by luggers, coast-guard, and other boats; 623 by ships and steamboats; 1535 by ships' own boats, &c.; and 198 by other means. The number of lives saved on or near the coasts of the United Kingdom in the 23 years 1856—1879 was 91,746. The number of inquiries held, 1878–9, before Wreck Commissioners at home, was 55; before magistrates, 76; in British possessions abroad, 165; and in naval courts abroad, 57.

SHIRA'Z, a celebrated city of Persia, and the capital of the province of Fars, in lat. 29° 41′ N., long. 52° 38′ E., was formerly a very flourishing city, and the ordinary residence of the Persian monarchs, but is now singularly divested of its ancient splendor. It is situated in a wide plain, on one of the limestone ledges which shoot out from the great West-Persian mountain system, 112 miles from the Persian Gulf, and 35 south-west of the ancient Persepolis (q. v.). It is inclosed by walls nearly four miles in circumference, and, previous to the great earthquakes which have repeatedly laid it in ruins, contained many splendid mosques, bazaars, caravansarais, and other public buildings. The houses, which are mostly built of stone, are superior in appearance to those of most other Persian towns; and the adjoining portion of the plain is of exuberant fertility, and is laid out in vineyards and in rose-gardens of great extent. The principal manufactures are silk, cotton, and woollen goods, cutlery, firearms, glass, and earthenware. The wine of S., which is very strong and resembles Tokay, is still famous throughout the East. Rose-water is also still prepared in large quantities. The trade of the town is transacted in the *Bazar-i-Wukell*, which is about a quarter of a mile long by 40 feet wide, and affords accommodation to several hundred shop-keepers. S. carries on trade with Yezd, Ispahan, and Bushire, from the last of which towns it receives Indian and European goods. The city was founded in 697 A.D., and from its beautiful situation and charming climate, became a favorite resort of the Persian princes; but a destructive earthquake in 1812 laid a large portion of it in ruins, and another in 1824, which cost the lives of 4000 of the inhabitants, completed the wreck of its prosperity. It was, however, rebuilt, and had obtained a pop. of 40,000 (its pop. previous to 1812 having been almost 60,000), when a third and more terrible visitation of this destructive agent, in April 1853, laid almost the whole town again in ruins, and caused the death of 12,000 people. It has since been partially rebuilt in a somewhat inferior style, and its pop. is now estimated at 25,000. It is celebrated for the number and eminence of the scholars and poets to whom it has given birth; chief of these is Sibuyah, the first of Arab grammarians; Hafiz (q. v.), the 'Anacreon' of Persia, whose tomb is half a mile north-east of the Ispahan gate; and Saadi (q. v.), whose mausoleum is 22 miles to the north-east.—See *History of Persia*, by Clements Markham, 1874.

SHIRE (Sax. *sciran*, to divide), a term which seems to have originated in the 8th c., and is applied to the districts, otherwise called counties, into which Great Britain is divided. A considerable number of the counties of England, as Kent, Essex, Surrey, Norfolk, Suffolk, were formed out of the petty kingdoms of the Anglo-Saxons, which, with the advancing tide of centralization, were gradually becoming consolidated into one great kingdom. As early as 800, an entry in the Saxon Chronicle relates that kings had ceased to reign among the *Hwiccas* (the inhabitants of the district afterwards known as Worcestershire), and that they were governed by an ealdorman acting under Cynwulf, king of Mercia. This substitution of ealdorman (or earls) for kings marks the gradual organization of the counties. It was sometimes found convenient to split up a kingdom into several shires. The civil, military, and judicial head of the shire was the ealdorman, whose office was not necessarily hereditary, though it had sometimes a tendency to become so. Twice a year he held the shire-mote, in which he and the bishop presided with equal jurisdiction. Among other questions which would come before the shire-motes were those that related to the boundaries of the respective shires. As a border thane pushed his occupation towards the frontiers of the shire to which he belonged, and came into collision with the occupants of the neighboring shire, questions necessarily arose which could only be settled by a compromise arranged by the two shire-motes, and these compromises may account for the irregular jagged boundaries which separate shire from shire, and occasional isolation of particular portions. Yorkshire, Durham, Cheshire, and Worcestershire derived their name from their ancient bishoprics. Various shires which had once an existence in the north, as Norhamshire, Islandshire, Hexhamshire, Hallamshire, Bamboroughshire, have merged into others. The term shire is nearly synonymous with county, yet not quite so, as there are certain counties with whose names the affix 'shire' is never used.

One explanation which has been given of this usage is, that the object of the addition of the syllable 'shire' is to distinguish the county from the town of the same name, and that it is therefore only applicable to counties bearing the same name with their county town. Another explanation is, that shire being a word of Anglo-Saxon origin, is not properly applied to any of the English counties except those which formed part of the larger Anglo-Saxon kingdoms. Neither of these reasons are exactly correspondent with the actual usage, by which shire terminates the names of all the English counties except the following: Northumberland, Cumberland, Westmoreland, Durham, Norfolk, Suffolk, Essex, Sussex, Middlesex, Kent, Surrey, and Cornwall. In Cheshire, we drop the final syllable of the town of Chester. Berkshire, Shropshire, and Hampshire are never used in their simple form, though sometimes abbreviated into Berks, Salop, and Hants. Shire is applied to all the Welsh counties except Anglesea.

In Scotland, the English tendencies of the sovereigns from the time of Malcolm Canmore to the war of succession, and the tide of immigration from the south, brought in, among other innovations, the division into shires. Its introduction seems to have begun early in the 12th century. Twenty-five shires or counties are enumerated in a public ordinance of date 1305. Nearly all the counties of Scotland may receive the terminal addition of shire. It is not applied to the island county of Orkney, and seldom to the counties of Bute and Caithness. Kirkcudbright is neither a shire nor a county, but a Stewartry. See STEWARTRY. The Irish counties are not generally called shires.

In England, south of the Tees, there was a sub-division of the shires into *hundreds*, which originally, in theory at least, seem to have been districts inhabited by 100 or 120 families; and were in some localities called *wapentakes*, these hundreds or wapentakes being further subdivided into *tythings*, inhabited by ten free families; and it became incumbent on every one to be enrolled in a tything and hundred for the purposes of civil government. In some of the larger counties there was an intermediate division to which that into hundreds was subordinate. Yorkshire had and still has its *Ridings*, (q. v.), Kent had its *Lathes*, and Sussex its *Rapes*. The division into hundreds and tythings never penetrated into the four northern counties of England, or into Scotland, where the *ward* and *quarter* were the immediate subdivisions of the county.

England possessed three *counties palatine*—Cheshire, Lancashire, and Durham—of which the earls formerly possessed all the judicial and fiscal powers of the crown, all now annexed to the crown (see PALATINE). Similar privileges belonged to the earldom of Stratherne in Scotland.

SHIRÉ, a river of South-eastern Africa, has its source in Lake Nyassa, from which it issues in lat. 14° 28′ S., and after a southerly course of 250 miles, joins the Zambesi. It flows through a cotton and sugar producing country of vast extent, is 80 to 150 yards broad, 12 feet deep, and never varies more than 2 or 3 feet from the wet to the dry season. Its current travels at the rate of 2½ knots an hour. The navigation is obstructed by cataracts over a space of 35 miles, in which it falls 1200 feet.

SHIRWA, or TAMANDUA, a lake of South-east Africa, north end 30 miles south-east of Lake Nyassa, lat. of center 15° 10′ S., long. 35° 40′ E. It is of an oval shape, tapering to the south; length, 60; breadth, 10 to 23 miles; and 1800 feet above the sea-level. It is surrounded by elevated land. On the west, between the lake and the River Shiré, Mount Zomba rises to 7000 feet. Several small rivers enter the lake on the south and west.

SHI'SDRA, or JISDRA, a town of European Russia, in the government of Kaluga, and 80 miles south-west from Kaluga, on the Shisdra, a branch of the Oka. It has manufactures of woollen cloth, glass-works, iron-works, tanneries, oil-factories. Pop. (1880) 11,703.

SHI'SHAK (in hieroglyphs, Shashank, the Susak, or Susakim of the Septuagint, and the Shishak of the Hebrew version, the Sessonchosis or Sesonchis of Manetho), the name of several monarchs of the 22d, or Bubastite Egyptian dynasty, supposed to have descended from foreign settlers in Bubastis, and to have been of Shemitic origin. The kings of this name were S. I., the first monarch of the dynasty, whose name is found in the portico built by the Bubastite dynasty at the great temple of Karnak, and on several statues of the goddess Pasht, which probably came from Luxor. Jeroboam fled to S. from the pursuit of Solomon, who wished to kill him, and lived there during the lifetime of Solomon. On the death of this monarch, Jeroboam quitted Egypt, and contended with Rehoboam for the possession of the crown. This struggle caused the division of the kingdom of David into two states, that of Israel and Judah. In the fifth year of Rehoboam, S. marched to Jerusalem with an army of 12,000 chariots, 60,000 cavalry, and an innumerable number of infantry, composed of Troglodytes, Libyans, and Ethiopians. He took the city, the treasures of the temple, and all the gold bucklers which Solomon had made. The conquest of Jerusalem is found recorded on the monuments of Karnak, on which S. I. is represented dragging before the God Ammon three files of prisoners, inscribed with various names of places, amongst which are Judæa, Mageddo,

Ajalon, Mahanaim, and other towns taken by S. in his line of march.

SHI'TTIM-WOOD. It is not certain what kind of wood is meant by this name in the Old Testament. The Ark of the Covenant was made of it, and probably it was a kind of wood distinguished both for beauty and durability. It has generally been supposed to be the wood of the *Acacia Nilotica*, which, however, is deficient in both these qualities. Another supposition is, that the wood of a species of olive is meant, *Olea similis*, which possesses them both, and is particularly remarkable for its durability.

SHIVES, a name used by cork-cutters to designate the small bungs used to close wide-mouthed bottles, in contradistinction to the phial-corks used for narrow-necked bottles.

SHO'A, a kingdom of Africa, the most southern division of Abyssinia, in lat. 8° 30′—10° or 11° N., long. 38°—40° 30′ E. Its boundaries, however, are by no means fixed, that on the W., where S. is bordered by the Galla tribes, being specially variable. An extensive tract in the east of the kingdom, between the capital, Ankobar, and the river Hawash is called Efat. The character of the country, and the condition of the people, are described under ABYSSINIA (q. v.).

SHOCK, COLLAPSE, AND REACTION. It is well known that some forms of injury, as, for example, a blow on the pit of the stomach, may occasion death without leaving any visible trace of their operation in the body, and, indeed, life may occasionally be destroyed even by sudden and powerful mental emotions. In such cases as these, death is said to result from shock, the actual cause of death being the sudden arrest of the heart's action, consequent on the violent disturbance given to the nervous system. Instead of actual death, the condition known as *collapse* is more frequently induced, in which the patient lies in a state of utter prostration, and apparently on the verge of dissolution. The face, and even the lips, are pale and bloodless; the skin is cold and clammy, and drops of sweat are often seen on the forehead. The features are contracted, and there is great languor in the general expression. There is extreme muscular debility, and the sphincter muscles sometimes relax, so that there is involuntary discharge of the contents of the bowels and the bladder. The pulse is quick, and so feeble as often to be almost imperceptible, and the respiratory movements are short and weak, or panting and gasping. The patient is in some cases bewildered and incoherent, in others drowsy, and sometimes almost insensible. Nausea and vomiting, with hiccup, are not unfrequent symptoms; and in the case of children, convulsions are often present.

When a person recovers from a state of collapse, he passes into a condition termed *reaction*, which often lasts for several hours. The first symptoms of this favorable change are improvements in the state of the pulse and the respiratory actions, recovery of the power of swallowing, an increased temperature, and an inclination to move from the supine position to one side. A slight degree of feverishness then often ensues, after which the skin becomes moist, the patient falls asleep, and awakes convalescent. As a general rule, the longer the symptoms of reaction are delayed, the greater is the danger, and if several hours pass without any sign of the commencement of reaction, there is little hope of recovery. If the reaction is imperfectly developed, a condition may supervene which is known as 'prostration with excitement,' which may terminate either fatally or favorably, and into the symptoms of which our limited space will not allow us to enter further than to remark that a peculiar delirium, closely resembling *delirium tremens*, is most commonly present.

The principal causes of collapse (as given by Mr. Savory in his article 'Collapse, and the General Effects of Shock upon the System,' in Holmes's *System of Surgery*) are :

'Injuries sudden and severe, or extensive, as contused and lacerated wounds, involving a considerable amount of texture—the crushing of a limb, for instance. Burns present familiar and striking examples of extreme collapse, produced by this cause. Under this head, too, come capital operations. Injuries of very important organs, as the liver or other of the viscera, or of the joints, or other organs abundantly supplied with nerves. Pain alone, when intense and protracted has proved fatal in this way; and it appears in a case related by Sir A. Cooper, that sudden relief from great agony was attended by the same untoward result. Certain poisons operate in this manner, depressing the system so suddenly and severely as to produce a state of collapse; tobacco, for example, and drastic purgatives have in some cases induced a similar condition.'

The effects of shock are aggravated by loss of blood; and hæmorrhage alone, if sudden and profuse, will produce collapse. General debility and old age favor the influence of the shock, and much depends upon the idiosyncrasy of the patient; an injury which will produce no apparent effect on one man, often producing a serious and persistent impression on another.

The following are the most important points in regard to treatment: The patient should be kept in a horizontal position, with the head on the same level as the body, and he should not be raised till decided symptoms of reaction appear. The best stimulus is brandy, given in the form of hot brandy and water. 'Its effects,' says Mr. Savory, 'are most certain and decided,' and it suits the stomach best. It will remain when all other stimulants are rejected. The state of the circulation and the temperature are the guide to its use. If no effects are apparent after an ounce or two have been swallowed, it is very questionable if any advantage will be gained from a larger quantity.' At the same time, heat should be applied to the pit of the stomach and the extremities, by means of hot flannel, hot-water-tins, or, in their absence, bottles containing hot water, and other appliances. Nourishment, in the form of beef-tea, should closely follow the stimulants; the two may be combined with the greatest advantage, and as the system rallies, the latter may be entirely replaced by the former.

In those cases in which a patient is in a state of extreme collapse from an injury requiring a capital operation, such as the amputation of a limb, the operation should be performed as soon as his condition will admit of it; and although it should not be undertaken while the prostration is extreme, it is not necessary, or even advisable, in Mr. Savory's opinion, to wait for complete reaction; and this is the opinion of most of our best surgeons. Moreover, in these cases, the use of chloroform is not expedient; for, in the first place, it cannot be safely administered to a patient so depressed; and, secondly, the chief reason for its employment is wanting, for a person in a state of collapse is comparatively insensible to pain. For further information on this subject, the reader is referred to Travers *On Constitutional Irritation*, and to the excellent article of Mr. Savory, from which we have freely borrowed.

SHODDY formerly meant only the waste arising from the manufacture of wool; it now has a wider and much more important signification, and is almost wholly understood to mean the wool of woven fabrics reduced to the state in which it was before being spun and woven, and thus rendered available for remanufacture. Woollen rags, no matter how old and worn, are now a valuable commodity to the manufacturer; they are sorted into two special kinds, the rags of worsted goods and the rags of woollen goods, the former being made of *combing* or long staple-wools, and the latter of *carding* or short-staple wools. The former are those properly known as *shoddy*-rags, and the latter are called *mungo*. Both are treated in the same way; they are put into a machine called a *willey*, in which a cylinder covered with sharp hooks is revolving, and the rags are so torn by the hooks, that in a short time all traces of spinning and weaving are removed, and the material is again reduced to wool capable of being reworked. It was formerly used as a means of adulteration and cheapening woollen cloths, but it is now found of greater advantage in making a class of light cloths adapted for mild climates and other purposes. The name is derived from *shed*. See WOOLLEN MANUFACTURES.

SHOEBURYNESS, on the coast of Essex and at the mouth of the Thames, faces the Nore. Since 1842 a school of gunnery has been established here, with artillery barracks, batteries, targets, and other appliances for experimenting on cannon.

SHOEING OF HORSES. In olden times, horses generally went unshod, as they now do in many eastern countries; but our Macadamized roads and paved streets, our fast paces and heavy loads, would speedily wear away the stoutest hoofs, and a rim of iron has accordingly been long in use as a protection. In style and pattern, the horse's shoe varies almost as much as his master's boot, and like it, when badly made, or unskilfully fitted, produces serious inconvenience, and even leads to accidents and diseases. When the feet are strong and properly managed, nothing is better than a plain shoe of tolerably uniform breadth and thickness, carefully fashioned to the shape of the foot. But many good authorities prefer what is called a seated shoe, which has a level part for the crust to rest upon, and within that the inner half of the shoe towards the sole surface is bevelled off. This seated shoe is thus wider than the plain shoe, and hence affords greater protection for a weak or flat sole. For faulty or diseased feet, special forms of shoes are suitable. In all healthy feet, the shoe should be fitted to the foot, and not, as is commonly done, the foot cut to fit the shoe. Another frequent error of keeping the shoe short and spare at the heels must be avoided. For roadsters, the toe of the fore-shoes should be slightly turned up, which greatly obviates tripping. The hind-shoes are generally thickened, and sometimes turned down at the heels. The number of nails required must vary somewhat with the weight of the shoe and soundness of the horn; five is the minimum, nine the maximum. It is important, however, that the shoes be firmly held on by as few nails as possible.

In a saddle-horse with sound feet, three on the outside, and two on the inside, should suffice to hold a well-fitted shoe. Horses for heavy draught are generally shod in Scotland with tips and heels, which afford increased firmness of tread, and greater power, especially when dragging heavy loads. To preserve the foot in a

sound state, the shoes should be removed every month. When the shoe is carefully taken off, the sole-surface on which it has rested should be rasped, to remove any ragged edges and any portions of adhering nails. Having for a month been protected from the wear to which the exposed portions of the foot are subjected, it will probably have grown considerably, and, in a stout hoof, will require to be cut down with the drawing-knife, especially towards the toe. Except in very strong feet, and in farm-horses working on soft land, the surface of the sole uncovered by the shoe seldom requires to be cut. It is the natural protection of the internal delicate parts, and must be preferable to the leather and pads often artificially substituted for it. The bars must likewise remain untouched, for they are of great service in supporting weight; whilst the tough, elastic frog must be scrupulously preserved from the destructive attacks of the knife, and allowed uninjured to fulfil its functions as an insensible pad, obviating concussion, and supporting weight. When the shoe is put on, and the nails well driven home, they should be broken off about an eighth or even sixteenth of an inch from the crust, and hammered well down into it. This obviously gives the shoe a much firmer hold than the usual practice of twisting off the projecting nail close to the crust, and afterwards rasping down any asperities that still remain. When the shoe is firmly clinched, the rasp may be very lightly run round the lower margin of the crust just where it meets the shoe, to smooth down any irregularities, but all further use of the rasp must be interdicted. The clinched nails, if touched, will only have their firm hold weakened; nor must the upper portions of the crust, which blacksmiths are so fond of turning out rasped and whitened, be thus senselessly deprived of those external unctuous structures, which render the unrasped foot so tough and sound, and so free from sandcracks.

To prevent the hoof becoming too dry and hard, it is advisable, especially in roadsters, and in hot weather, to stop the feet several times a week with a mixture of equal weights of lard, tar, bees-wax, and honey, with about one-fourth part of glycerine, melted together, well stirred, and preserved in pots for use. Fuller details on this subject will be found in a little volume entitled *Notes on the Shoeing of Horses*, by Lieutenant-colonel Fitzwygram, 15th (the King's) Hussars; and in a paper on 'Horse-shoeing,' by Mr. Miles, published in the *Journal of the Royal Agricultural Society of England*, and reprinted in a separate form by Mr. Murray, Albemarle Street, London.

SHOES, SHOE-TRADE. Clothing for the feet, whether in the form of sandals or shoes, has been in use in every country aspiring to civilization in ancient and modern times. The rudimentary shoe is a sandal consisting of a sole, held to the foot by straps and thongs, as represented in fig. 1. Such were the common Egyptian and Greek shoes, to which the shoes of the peasantry of the Abruzzi, in the south of Italy, bear a close resemblance. In Egypt, however, the ordinary materials for shoes were strips of the papyrus interwoven like a mat; an example of a sole of this kind is given in fig. 2. As is seen from paint-

Fig. 1.

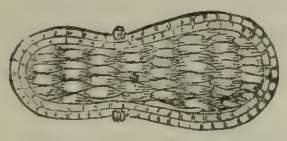

Fig. 2.

ings on the walls of Thebes, shoemaking formed a distinct trade in the reign of Thothmes III., 1495 B.C., or about the period of the flight of the Israelities. In the adjoining illustration, fig. 3, a sketch is presented from Thebes of two Egyptian shoemakers at work, with the tools of their profession beside them. The

Fig. 3.

streets of Rome were encumbered with the stalls of shoemakers in the reign of Domitian. The shoe of the ancient Hebrews was a species of sandal. For ladies, the sandal, translated 'shoe,' in the scriptures, was highly ornamental: 'How beautiful are thy feet with shoes, O prince's daughter' (Cant. vii. 1). Ornamented slippers are still a luxury in the East. The foot-coverings of the Romans were various in character, from the simple sandal and slipper to the boot, which extended up the leg. When the shoe covered the whole foot, it was termed *calceus;* the calceus of a particular form and of great strength worn by the Roman soldier was known as *caliga*.

Reference is made in Scripture to different symbolical usages in connection with sandals or shoes. The delivery of a shoe was used as a testimony in transferring a possession: 'A man plucked off his shoe, and gave it to his neighbor: and this was a testimony in Israel' (Ruth iv. 7). In cases of this kind, the throwing of a shoe on a property was a symbol of a new proprietorship or occupancy: 'Over Edom will I cast my shoe' (Psalm lx. 8). From these ancient practices, in which the shoe was symbolical of contract, perhaps comes the curious old custom in England and Scotland of throwing old shoes for good luck after a bride and bridegroom on departing for their new home.

St. Crispin and his brother Crispinian have long been regarded as the patron saints of shoemakers. According to medieval legend these personages were natives of Rome, and having become converts to Christianity, traveled into France and Britain to propagate the faith, everywhere supporting themselves by making shoes, which they sold to the poor at a very low price—one part of the legend being that an angel supplied them with leather. It is said that they suffered martyrdom in England towards the end of the 3d century. The memory of St. Crispin, of whom we chiefly hear has, from time immemorial, been kept up by processions and other festivities in his honor on October 25, which is known as 'St. Crispin's Day.' Under this saintly tutelage, shoemaking has attained to the distinctive appellation of the 'gentle craft;' and is noted for the number of individuals who have risen from it to eminence. See an amusing but scarce work, *Crispin Anecdotes;* and a trade newspaper called *St. Crispin*. The sedentary and solitary nature of the craft, as hitherto conducted, has possibly had some influence in producing a degree of thoughtfulness, while the act of hammering his leather is calculated, as some imagine, to stimulate the mental energy of the operative. If there be any real virtue in the sitting attitude of the shoemaker, a corresponding evil attends that method of carrying on his operations.

In every profession, sitting at work in a close atmosphere is particularly injurious to the health. Statistics assure us that out of 10,000 artisans who sit at their labor, 2577 fall sick, and 95 die annually; whilst as regards an equal number of those who alternately sit and stand, only 1713 sicken, and 61 die. To remedy this crying evil, a member of the profession, Mr. J. Sparkes Hall, London, has invented a simple and inexpensive work-bench, at which shoes may be made standing. Of this standing-bench, we offer a sketch in fig. 4. A few days' practice, we are told, renders

Fig. 4.

the workman as expert with the standing-bench as if he were seated according to the old plan, and he can execute closing with less fatigue and considerably more cleanliness. The only kinds of work in which sitting is more convenient are rounding the soles, lasting, and fitting. This standing-bench is, however, not much adopted by the men, who prefer old usages.

The fashion of shoes, as has occurred with other articles of dress, has undergone innumerable changes. At one time, shoes were pointed to an extravagant degree; and in last century, the high heels of ladies' shoes became a monstrosity. Shortly after the beginning of the present century, the most marked improvement was the making of shoes right and left; the substitution of latchets for buckles about the same period was also a step in advance. In our own day, the general disuse of the shoe proper, and the introduction of short ankle-boots, are the chief changes

of fashion. A proposal for a more perfect adaptation of shoes and boots to the shape of the foot, is noticed under FOOT.

The shoemaking trade, as at present conducted in Britain, is divided into two departments—the bespoke and the ready-made or sale business. The larger department hitherto has been that in which customers bespeak boots and shoes by having them made to measure; but it is generally giving way to the plan of buying articles ready-made. The cause of this is exceedingly obvious. The process of measuring is usually very imperfect, owing, among other reasons, to the want of lasts to suit every variety of feet as well as the too general indifference to meet individual peculiarities. On this account, and even at the risk of purchasing an inferior class of goods, the public are becoming daily more disposed to encourage the ready-made trade. Accordingly, large quantities of boots and shoes in innumerable varieties are now made and supplied wholesale by manufacturers for the retail dealers. Northampton, Stafford, and Leicester, are considerable seats of this manufacture in England; and from certain districts in France, there are increasing importations, chiefly of a cheap kind of ladies' shoes.

The plan of making boots and shoes by isolated workmen at their own homes, has been found quite incompatible with the modern necessities of trade. As in the case of the handloom weaver, the shoemaker of the old school has had to succumb to machinery. After an unsuccessful struggle to oppose the introduction of sewing-machines, these are now coming generally into use, and men are employed in large numbers together in what may be called shoe-factories. Northampton and Stafford, the two chief of the centers just named, have unquestionably benefited by the introduction of the sewing-machine, although it deranged the relations between the masters and men for a time. An instructive and valuable exhibition of the leather and shoe trades was held at Northampton in 1873, illustrating the high pitch of excellence which these trades have now attained.

This manufacture has long been a staple trade of Massachusetts, in which state the quantity of boots and shoes fabricated annually is numbered by millions of pairs. Recently, a machine has been introduced into the American shoe-trade for fixing the soles to the uppers by means of pegs, the inventor being a person in Salem, Massachusetts. A pair of boots or shoes can be pegged in two minutes. These pegged goods are disposed of wholesale in boxes, and may be seen in retail stores all over the United States. As evidence of the important character of the shoe-trade in Massachusetts, it may be mentioned that a few years ago there were as many as fifteen members of the 'gentle craft' in the legislature of that state. Ingenious machines have also been introduced for fastening the soles to the uppers by means of fine screws. They were shown at the International Exhibitions of 1862 and 1867, at work, uncoiling lengths of wire, making the end into a screw, cutting off a small piece, piercing a hole in the sole, and screwing the wire therein.

There are no means of determining the extent of this trade in England or the United Kingdom. All that can be done is to state the amount of imports and exports. The boots and shoes imported in 1876 were 109,906 doz. pairs, having a value of £328,540. These are entered among the customs tables as leather manufactures; but as very few boots and shoes are actually without leather, nearly all are probably included here. The exports in 1876 were 441,632 doz. pairs, value £1,403,466; in 1880, 420,189 doz. pairs, value £1,282,221 (of which nearly half were sent to Australia). The export trade varied as follows:

	Dozen pairs.	Value.
1865	439,283	£1,462,105
1867	274,036	952,804
1869	436,329	1,326,792
1871	510,648	1,513,665
1873	526,460	1,704,145
1875	462,104	1,509,639

SHO'LA, the white pith of the leguminous plant *Æschynomene aspera*, a native of the East Indies. With this substance, which is exceedingly light, the natives of India make a great variety of useful articles, especially hats, which being very light and cool, are in great request. Helmets made of Shola are much used by the British troops in India.

SHOOTING, with intent to wound, is felony in the law of England, and punishable with penal servitude for life. The offence consists in shooting at another, or drawing a trigger, or in any other manner attempting to discharge loaded arms. It is not, however, an offence unless there was a possibility of injuring some person; the intent must not only exist, but the relative situation of the parties must be such that serious injury might have ensued. The extent of the actual wound is immaterial.

SHORE. See SEA-SHORE.

SHORE, in Ship-building, is a strong prop or stanchion placed under the bottom or against the side of a ship, to keep her steady on the slip or in dock. Shores are also used to support or prop up a building during alterations.

SHOREDITCH. See TOWER HAMLETS.

SHO'REHAM, NEW, a seaport, and parliamentary borough of Sussex, on the left bank and at the mouth of the Adur, six miles west of Brighton. The town arose when the harbor of Old Shoreham, now a mile inland, became silted up. Pop. of the parish (1881) 3572. Ship-building is carried on here on an extensive scale, and the trade of the port is considerable, principally with France and the coast. In 1880, 802 vessels, of 90,721 tons, entered, and 817 vessels, of 91,683 tons, cleared the port. About 160 vessels belong to S., of which a large number are employed in the oyster-trade. The parliamentary borough, which includes the *Rape* (see SUSSEX) of Bramber, contains (1881) 42,442 inhabitants.

SHORTHAND. The problem which inventors of systems of shorthand have attempted to solve, is thus formulated by Peter Bales, a writing-master and stenographer who lived towards the end of the sixteenth century—'to write as fast as a man speaketh treatably.' 'This,' he says, 'may, in appearance, seem difficult; but it is, in effect, very easy, containing a many commodities under a few principles, the shortness whereof is attained by memory, and swiftness by practice, and sweetness by industry.' Although three hundred years have elapsed since this assertion was made, it has not yet been realized to the extent anticipated.

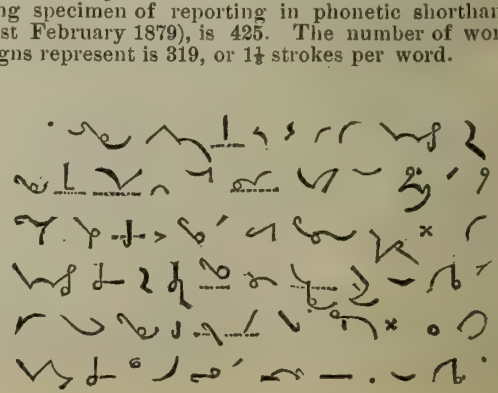
The publication, in 1837, of Mr. Isaac Pitman's system of shorthand, entitled 'Phonography,' in which the stenographic signs or letters represent the *sounds* of the English language, marks a new era in the art. The legibility which this principle secures has led to the very general use of shorthand in merchants' and lawyers' offices, and in railway and ordinary correspondence, it has also promoted the establishment, in England, of a dozen shorthand periodicals. A vigorous propagandism, and instruction books at low prices, have aided in giving to this system its well-merited distinction above all others in public estimation. At the end of the last century, the price of a treatise on shorthand was a guinea, and a course of lessons in the art was charged five or ten guineas. In contrast with this, Mr. Pitman's system is published in a compendious tabular form for a penny, and he has organized a Phonetic Society, extending throughout Great Britain and Ireland, whose members invite learners to send their lessons through the post for gratuitous correction.

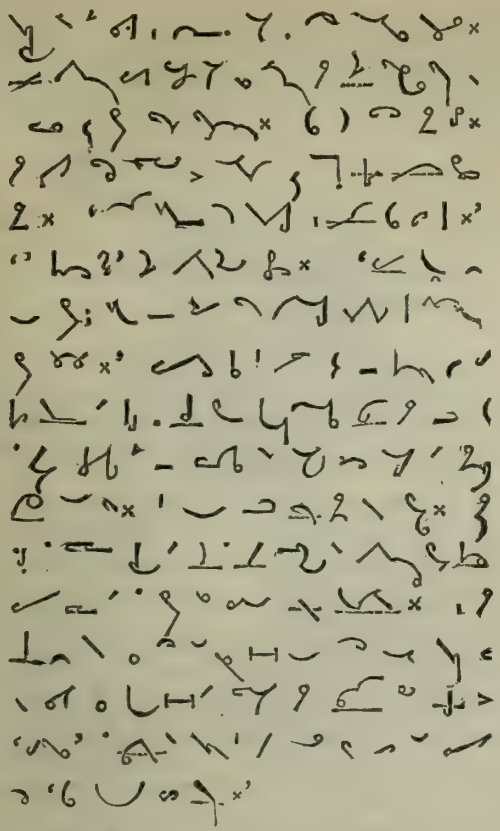
Before giving a brief description of this system of shorthand, we may note the conditions on which alone Peter Bales's reasonable anticipation of the future universal practice of shorthand can be realized, and then it may be seen if phonography fulfils these conditions.

Given a language, say the English, it is required to provide signs for its expression which may be written at the rate of speech in a public assembly, which ranges from a very slow utterance of 60 words in a minute, with frequent pauses, to a rapid flow of 180 words in a minute. The average of public speaking is a mean between these extremes—that is, 120 words a minute, or two words per second. A dexterous penman can make 180 separate simple strokes or dots in a minute. The required system of shorthand must, therefore, represent two words by three strokes (or dots), or by one and a half strokes per word. Let the reader try his hand upon such signs as

(the last two struck upward), and he will feel assured that there is no error in the conclusion to which he will be brought.

The number of pen strokes and dots or short vowel marks in the following specimen of reporting in phonetic shorthand (*Phon. Jour.*, 1st February 1879), is 425. The number of words which these signs represent is 319, or 1⅓ strokes per word.





Key.—An enterprising reporter had heard that the late Lord Palmerston was to be present at an archery meeting in a small country village in Hampshire, and he accordingly posted down to the place, and waited for something to turn up. Lord Palmerston's task was to distribute prizes to some half-dozen blushing young ladies, and the whole company present didn't number much above a score. His lordship performed the task with his usual grace and good humor, giving the young ladies a paternal pat on the head, but making only the most commonplace observations. Our reporter waited anxiously until, to his horror, he saw the proceedings brought to a close without a speech from the Premier. This was more than he could stand. He rushed from his corner to the noble lord, who was getting out of the room as fast as he could: 'My lord, I beg your pardon, but really this will not do.' 'What do you mean?' was the reply of the astonished statesman. 'Why, you've made no speech; I've come all the way from London to report it, and I must have a speech of some sort.' Whereupon it is on record that the good-tempered old gentleman turned back, and detained the audience for twenty minutes while he gave them a genial dissertation on the good qualities of English women in general, and Hampshire lasses in particular. On another occasion, however, he made up for this. He was attending an agricultural dinner, and saw a large gathering of reporters, for the times were critical, and a speech of his certain to be valuable. But he had made up his mind not to speak—no man knew better when to hold his tongue—and accordingly he slyly sent down to the 'gentleman of the press' a slip of paper, on which, in his bold round hand, were the words: 'This fish won't bite!'

We have seen that the pen can produce 1½ strokes per word uttered at the rate of 120 per minute. The pen is therefore ahead of the speaker, and in a burst of oratory could record 200 words in a minute. In this calculation the reporter has the further advantage, that this estimate is based on the number of *separate* strokes which the pen can make in a minute, whereas *joined* strokes can be written more rapidly than single ones; thus

take less time than

&c. In the above specimen only 130 words are written by single strokes, and the remaining 295 words or phrases (for several words are often linked together in one shorthand outline) are composed of from 2 to 4 strokes combined in one stenographic form.

Words can be recognized, either in longhand or shorthand, by their consonants alone; and the simple strokes employed in shorthand to represent the consonants may be placed in three positions, *above, on,* or *through* the real or imaginary line on which the writing is placed. The twelve simple or pure vowels and five diphthongs in the English language may be arranged in three classes, according to the nature of the sounds, as below. The vowel of any given word, or rather the class of vowels to which it belongs, may therefore be understood by the *position* which the consonant part of the word takes with respect to the line. The alphabet of phonography is:

CONSONANTS.

p b t d ch j k g

f v th th s z sh zh

(*thin*) (*then*)

l r (up) m n ng w y h

VOWELS.

Long. ah, eh, ee, aw, oh, oō

palm *pate* *peat* *pall* *bone* *pool*

Short. ă, ĕ, ĭ, ŏ, ŭ, o͝o

pat *pet* *pit* *poll* *bun* *pull*

DIPHTHONGS.

ei, eu, ou, ai, oi

pine *new* *now* *ay* (*yes*) *boy*

The vowel and diphthong signs are the dots, dashes, and small angular marks; the upright stroke to which they are placed (the shorthand letter *t*) is introduced to show the *position* in which the vowel sign is written with respect to *all* consonants. These 17 vowel-signs may be distributed into three classes, all the sounds in each class having a common characteristic; thus:

Class 1.—Ah, ă; au, ŏ; ei, ai, oi, = 7, in each of which, except *ei*, the broad sound of *ah* or *aw* is heard.

Class 2.—Eh, ĕ; oh, ŭ, = 4, intermediate sounds between *ah* and *ee*, and between *aw* and *oo*.

Class 3.—Ee, ĭ; ōō, o͝o; eu, ou, = 6, in each of which the close *ee*, or close *oo*, predominates.

By adding a hook or small circle to the consonants, by halving, and by lengthening, double and treble letters are produced, on the following plan:

Straight Lines.

p pl pr sp spr pf pn ps pns pt

Curves.

n nl nr sn nn ns nt ntr

This principle is applicable to all the consonants, and conduces to the brevity of the system.

The shorthand letters, both vowels and consonants, are employed first as component parts of words, and secondly each letter is made the representative of some common word in which the letter is prominently heard; thus \ *p* represents *up*, | *t* stands for *it*, / *ch* for *which*, — *k* for *come*, ∖ o͝o for *to*, &c.

The most frequently occurring words, *the, and, of, in, to,* &c., are selected for this distinction, and are called grammalogues, or letter-words; and the shorthand letters, when thus employed, are logograms or word-letters. In the 'learners' style' of phonography only 50 grammalogues are used; in the ordinary or 'corresponding style' there are 150 (which amount to one-half of the language, on common subjects); and in the 'reporting style' the number is largely increased, for every short word becomes a grammalogue on the principle of omitting its vowel and writing the consonant form *in position* with respect to the line, *above, on,* or *below,* to denote a vowel of the first, second, or third class.

Phonography is a growth of the age, and is the lineal descendant of the 200 different systems that have been published since the

appearance of the first system of modern shorthand in 1588. It carries out fully the principle which all previous systems acknowledge, but do not faithfully apply—namely, that of enlarging the ordinary 26-letter alphabet. Those systems add to the alphabet three signs for *ch*, *th*, and *sh*; but these are not all the consonants in which our alphabet is deficient. Two signs are required for *th*, as pronounced in *thin* and *then*, one for *ng* in *sing*, and one for *zh* in *pleasure* (plezhure). But the principal defect in the ordinary systems of shorthand is in their vowel notation. They contain but five signs for the five vowels *a*, *e*, *i*, *o*, *u*, which, single and combined, represent 17 different sounds. This disparity between the sounds of the language and the means of representing them made the reading of shorthand exceedingly difficult and uncertain.

In the last century three systems were published, by Tiffin, 1750; Lyle, 1762; and Holdsworth and Aldridge, 1768; and in the present century five systems have appeared, by Row, 1802; Towndrow, 1831; Pitman, 1837; De Staines, 1839; and Bell, 1857, based on the phonetic principle; but excepting phonography, they were wanting in all the main requisites of a shorthand system—simplicity of construction, facility in execution, and elegance in effect.

The shorthand of the Romans, practised by Tiro, first the slave and afterwards the freedman of Cicero, was really an abbreviated longhand. The Roman letters were shorn of their just proportions, initial letters often served for whole words, and terminations, in which Latin abounds, were either abbreviated or omitted. By systematizing these mutilations, Tiro constructed a system of swift writing, which served him, as Cicero's amanuensis, in good stead, and doubtless we owe to it much of what remains to us of the writings of Cicero.

The history of shorthand, properly so called, with an alphabet of simple signs as substitutes for the ordinary letters, dates from the reign of Elizabeth. Dr. Timothy Bright, a learned man, the author of several medical works, and the compiler of an abridgement of John Fox's *Book of Acts and Monuments of the Church*, in the year 1588 published 'Charactery; an Art of Short, Swift and Secret Writing by Character.' In this ingenious work Bright claims the invention of the art of shorthand. His claim may justly be disputed, for his system is not shorthand in the present sense of the word. It is not based on a shorthand alphabet, but is a system of arbitrary marks for words: thus *abound*, *about*, *accept*, *accuse*, *advance*, &c.

Two years after the appearance of this work, Peter Bales published *The Writing Schoolmaster*. This system also was composed of arbitrary characters.

In the year 1602, a little above threescore years before Wilkins published his celebrated 'Essay towards a Real Character and a Philosophical Language' (1668), appeared 'The Art of Stenography, or Short Writing, by Spelling Charactery, invented by John Willis, Bachelor in Divinity.' The author intimates in the title of the work the grand distinction between it and the previous attempts that have been made in the art, by describing it as '*spelling* charactery' the others having been *verbal* charactery. John Willis's alphabet is:

a b c d e f g h i j k l m n o

p q r s t u v w x y z

The inadequacy of this alphabet is proved by the fact that not one of its letters was used in the same sense by the inventors of systems in the following century, when shorthand began to be popular. Sixteen years after the publication of John Willis's system, Edmund Willis published 'An Abbreviation of Writing by Character' (1618). This system exhibits a considerable improvement in its alphabet, and fifteen of its letters were adopted by subsequent shorthand authors.

The next name on the roll of shorthand authors deserving of mention here is that of Rich, 1654—1669. His system was used by Dr. Doddridge, who reprinted it for the benefit of his theological students, and strongly recommended its adoption by young persons.

Mason followed in 1672—1707. The alphabet has now become much simplified. Mason's system was adopted by Thomas Gurney in 1740, and has since been known as Gurney's shorthand. In the earliest edition to which we have access (1753), there is no mention of Mason as the inventor of the system.

The principal shorthand authors in the eighteenth century were Macaulay, 1747; Angell, 1758; Byrom, 1767; Taylor, 1786; and Mavor, 1789; and in the present century, Clive, 1810; Lewis, 1815; Moat, 1833; Pitman, 1837; Fancutt, 1840; Bradley, 1843. Of these systems, except Pitman's phonography, the one that has obtained the greatest amount of popularity is Taylor's and a few private persons and reporters use it to the present day. Its alphabetic signs are well chosen, but, as we have already noticed, it fails to supply signs for three consonant sounds heard in the English language, and it makes no pretension to express all the vowel and dipthong sounds. The following is Taylor's alphabet:

b c d f g h j k l m n

p q r s t v w x y z

ch sh th

The reader who wishes to learn a good practical shorthand, is referred to Pitman's *Phonographic Teacher* and other publications, published by Fred. Pitman, 20 Paternoster Row, London.

SHORT-SIGHT. See SIGHT, DEFECTS OF.

SHOT is a term applied to all solid balls fired from any sort of firearms; those for cannon and carronades being of iron, those for small arms, of lead. The latter are known as bullets and small-shot. The shot used for guns at present vary from the 3-pounder, for boat and mountain artillery, to the 13-inch shot, which weighs about 300 lbs. as a shell, or 700 lbs. as an elongated bolt. Generally, shot are cast. There are simple practical rules for calculating the weight of *spherical* shot from the diameter, and *vice versâ*, which are often useful in reading of artillery actions. Given the diameter in inches, to find the weight in pounds: Cube the diameter, and multiply the result by 14; reject the two right-hand figures; those remaining give the weight in pounds.—Given the weight in pounds, to find the diameter in inches: Multiply the cube-root of the weight by 1·923, and the result is the diameter of the shot in inches.

Small-shot is of various sizes, from swan-shot, nearly as large as peas, to dust-shot. It is made by dropping molten lead through a colander in rapid motion from a considerable height into water. The lead falls in small globular drops. The holes in the colanders vary in size according to the denomination of the shot, No. 0 requiring holes $\frac{1}{10}$th inch in diameter, No. 9, $\frac{1}{160}$th inch. The colanders are iron hemispheres, 10 inches in diameter, and are coated within with the *cream* or scum which is taken off the molten metal. A small portion of arsenic is melted with the lead, and the fusion in the colanders is maintained by those vessels being surrounded by burning charcoal. The discovery of the advantage attending a long fall was made in England towards the end of last century. Previously the shot had dropped from the colanders at once into the water. The lead was then so soft that the shot were flattened by the water. The fall through the air enables the lead to cool and harden before taking its plunge. The smaller sizes require less fall than the larger—100 feet suffices for sizes Nos. 4 to 9—the larger sorts demand 150 feet. The highest shot tower is at Villach in Carinthia, where there is a fall of 249 feet. After cooling, shot is sifted in successive sieves to separate the sizes. Misshapen shot are found by their inability to roll: and finally, the whole are polished by rotary motion in small octagonal boxes, in which a little plumbago has been thrown. See also CASE-SHOT or CANISTER-SHOT, and GRAPE-SHOT.

SHOTTS, a small and ancient village of Lanarkshire, close to the Kirk of Shotts, about 16 miles east of Glasgow. About 3 miles to the south-east of the Kirk, modern S., or S. Proper, began to rise at the close of the last century, when the Shotts Iron Company erected their extensive iron works there. S. may be said to consist of three villages—viz., Stane, Shotts Iron-works, and Dykehead, of which the united population in 1881 was 2985. In the same year, the population of the civil parish of Shotts was 11,214. Valuable coal and ironstone, peculiarly suited for the manufacture of iron, abound in the district, and a large number of workmen are employed in iron-making and moulding. Until recently, there was no railway communication from and to S. for passengers; but since the opening of the Clelland and Midcalder branch of the Caledonian Railway, S. forms the half-way station between Edinburgh and Glasgow on that line.

SHOULDER-JOINT, THE, is a ball-and-socket joint. The bones entering into its composition are the humerus or arm-bone, and the scapula or shoulder-blade, the large globular head of the former being received into the shallow glenoid cavity of the latter, an arrangement by which extreme freedom of motion is obtained, while the apparent insecurity of the joint is guarded against by the strong ligaments and tendons which surround it, and above by the arched vault formed by the under surface of the acromion and coracoid processes. See SCAPULA. As in movable joints gener-

ally, the articular surfaces are covered with cartilage, and there is a synovial membrane which lines the interior of the joint.

The most important connecting medium between the two bones is the capsular ligament, which is a fibrinous expansion embracing the margin of the glenoid cavity above, while it is prolonged

Fig. 1.—The left Shoulder-Joint and its Connections.

1, the clavicle or collar bone; 2, the acromion process; 3, the coracoid process; 4, the capsular ligament; 5, the coracohumeral ligament; 6, the tendons of the biceps muscle; 7, the shaft of the humerus or arm-bone; 8, the greater tuberosity of the humerus; 9, the lesser tuberosity; 10, the neck of the scapula; 11, anterior surface of the scapula.

upon the tuberosities of the humerus below. From its relations with the surrounding muscles, the ligament derives much of its strength. Accordingly, in paralysis of the arm, one or two fingers can often be pressed into the joint towards the head of the glenoid cavity, from which the head of the humerus is now separated.

The shoulder-joint exhibits the following varieties of motion: 1. Flexion, to a great extent; 2. Extension, in a much more limited degree; 3. Adduction, in an oblique direction, forwards and inwards; 4. Abduction very freely; 5. Circumduction; and 6. Rotation slightly.

The morbid affections of the shoulder-joint may be divided into (1) those arising from disease, and (2) those dependent on an accident. The most common diseases are acute and chronic inflammation of the joint, which often terminate in its anchylosis or immobility. The principal accidents are fractures and dislocations. There may be fracture (1) of the acromion process, or (2) of the coracoid process, or (3) of the neck of the scapula, or (4) of the superior extremity of the humerus; or two or more of these accidents may be associated. Again, the head of the humerus may be dislocated from the glenoid cavity as the result of accident in three different directions—viz. (1), Downwards and inwards into the axilla, which is by far the most common form; (2) Forwards and inwards; and (3) Backwards on the infra-

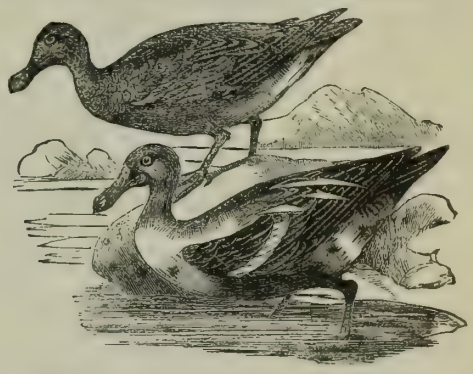
Fig. 2.—Dislocation of the Shoulder-Joint downwards.

1, the clavicle; 2, the acromion process; 3, the coracoid process; 4, the glenoid cavity; 5, the head of the humerus lying in the axilla.

spinous fossa, or the dorsum of the scapula. The first of these varieties is of such common occurrence, that persons of ordinary intelligence should know how to recognize, and even (in an emergency) to treat it.

The bones are in the position shown in the figure; and the following are the most prominent symptoms: 'The arm is lengthened; a hollow may be felt under the acromion, where the head of the bone ought to be; the shoulder seems flattened; the elbow sticks out from the side, and cannot be made to touch the ribs; and the head of the bone can be felt if the limb be raised, although such an attempt causes great pain and weakness, from the pressure exerted on the axillary plexus of nerves.'—Druitt's *Surgeon's Vademecum*, 8th ed. p. 282. There are at least five methods of treating this form of dislocation. It is sufficient to notice two of them. 1. Reduction by the heel in the axilla. The patient lies on a couch, and the operator sits at the edge, and puts his heel (the shoe or boot being previously removed) into the axilla, to press the head of the bone upwards and outwards, and at the same time pulls the limb downward by means of a towel fastened above the elbow. There is a figure of this operation in the article DISLOCATIONS. 2. Reduction by the knee in the axilla. The patient being seated in a chair, the surgeon places one of his knees in the axilla, resting his foot on the chair. He then puts one hand on the shoulder, to fix the scapula, and with the other depresses the elbow over his knee.—For a description of the symptoms and mode of treatment of the other forms of dislocation, and of the different varieties of practice, we must refer the reader to any systematic treatise on Surgery.

SHO'VELLER (*Rhynchaspis*), a genus of ducks of the section having no lobe or pendent membrane on the hind toe, and remarkable for the expansion of the end of the mandibles in adult birds, particularly of the upper mandible. The lamellæ of the man-



Shoveller, female and male (*Rhynchaspis clypeata*).

dibles are long and very delicate. The legs are placed near the center of the body, so that these birds walk much more easily than many of the ducks. The Common S. (*R. clypeata*) is smaller than the wild duck, but rather larger than the widgeon. The S. is a winter visitant of Britain, but not very common. A few remain all the year. It is widely distributed over Europe, Asia, and North America. Its flesh is very highly esteemed. A species of S. is found in Australia.

SHOWERS OF FISHES have occasionally fallen in different parts of the world, exciting great astonishment. Instances of this kind have occurred in Britain. A few years since, a shower of small three-spined sticklebacks fell near Merthyr-Tydvil in Wales, sprinkling the ground and house-tops over an area of at least several square miles. They were alive when they fell; yet if caught up by a whirlwind from any of the brackish ponds near the sea in which this species of fish abounds, they must have been conveyed through the air a distance of almost thirty miles. Another similar instance occurred at Torrens, in the isle of Mull, in which herrings were found strewed on a hill five hundred yards from the sea, and one hundred feet above it.

Showers of fishes occur much more frequently in those tropical countries where violent storms, sudden gusts of wind, and whirlwinds are most common. In India, a shower of fishes varying from a pound and a half to three pounds in weight has been known to fall. Sometimes the fishes are living, more frequently they are dead, and sometimes dry or putrefying. They are always of kinds abundant in the sea or fresh waters of the neighborhood; and it cannot be doubted that they are carried up into the air by violent winds or whirlwinds; although they sometimes fall at a considerable distance from any water which could supply them. The sudden reappearance of fresh-water fishes in ponds which have been dried up for months in tropical countries, is often popularly ascribed to their falling from the clouds; but the truth is, that they have been buried in the mud below, existing probably in a state analogous to that of animals in cold climates during hybernation. A pool, the bottom of which has long been dry, and on which grass has grown and cattle have walked, is again filled with fishes in a few hours after it is filled with water.

SHRA'PNELL SHELL. See SHELLS.

SHREW (*Sorex*), a genus of small quadrupeds of the family *Soricidæ*. They are often popularly confounded with mice and rats, but are really very different, having insectivorous and not rodent teeth. The head is very long; the snout elongated, attenuated, and capable of being moved about; the eyes small; the tail long; both body and tail covered with fine short hair; the feet have a broad sole and 5 toes. The genus has recently been subdivided, and the British species belong to more than one of the subdivisions. The COMMON S. of Britain (*S.* or *Corsira vulgaris*) was, until recently, confounded with *S. araneus*, a species common in continental Europe. It is nearly 2¾ inches in length from the snout to the root of the tail, the length of which is about

Common Shrew (*Sorex vulgaris*).

1¾ inches. It abounds in dry fields, gardens, and hedge-banks; feeding chiefly on insects and worms, for which it grubs with its long snout amongst the roots of the herbage. It burrows, and makes long *runs* just under the surface of the ground. It is an excessively pugnacious little animal, and the males have fierce combats in spring, in which many are killed. Cats kill the S., but do not often eat it, probably on account of its strong musky smell; but it is the prey of weasels, hawks, owls, and shrikes. Harmless and inoffensive as it is, it has long been very generally regarded with dread and aversion by the vulgar. (See White's *Natural History of Selborne*.)—Another and even smaller species, *S. pygmæus*, is found in Ireland, where it is called the Shrew Mole.—The WATER S. (*S. fodiens* or *Crossopus fodiens*) is larger than the Common S., being fully 3 inches long, and the tail 2 inches. It is of a blackish-brown color, gray or white on the underparts. It burrows in the banks of streams, and is very aquatic in its habits. It is found in many parts of Britain.—Some of the Indian species of S. attain a much larger size, as that called the Musk Rat (q. v.). There is an Italian species which is the smallest of all known Mammalia. It is only about 1½ inch in length, exclusive of the tail, which measures about 1 inch.

SHREW MOLE (*Scalops*), a genus of insectivorous Mammalia, of the family *Talpidæ*, and very nearly allied to the moles. There are 6 incisors, 2 canine teeth, 8 false molars, and 6 true molars in each jaw. The ear is destitute of auricle; the eyes are very small, and much concealed; the feet are 5-toed, the fore-feet large, as in the mole. The whole figure, and also the habits, resemble those of the mole.—There are several species, all natives of North America.

SHREW'SBURY, a parliamentary and municipal borough and market-town, the capital of Shropshire, stands on the Severn, by which it is nearly surrounded, 163 miles north-north-west of London by the London and North-western Railway. It is irregular in plan, contains many inferior houses, partly built of timber, but often of very picturesque appearance. In the modern quarters, the houses are handsome and regular. Two bridges, the 'English' and the 'Welsh,' cross the Severn, and connect the town with the suburbs of Abbey-Foregate and Coleham on the east, and Frankwell on the west. To the north, is the other suburb of Castle-Foregate. The town contains interesting remains of the ancient walls, the castle, two monasteries, and a Benedictine abbey. The remains of the Abbey Church now form the church of Holy Cross. There are other ecclesiastical edifices, a Free School, with an income from endowment of £3100 a year, and 22 exhibitions to the universities; a number of other important schools, institutes, hospitals, &c. The Town and County Hall, the Public Rooms, a handsome Greek structure, and the Market-hall, erected in 1867—1868, in the Italian style, are worthy of mention. S. carries on manufactures of linen-thread, canvas, and iron-wares, and there is a salmon-fishery on the Severn. The Brawn and 'Shrewsbury Cakes' made here have long been held in esteem. The borough returns two members to the House of Commons. Pop. (1871) 23,406; (1881) 26,478.

S., called by the Welsh Pengwern, was named by the Anglo-Saxons *Scrobbes-Byrig*, and of this the modern name is a corruption. The town connects itself intimately with the history of the country from the 12th to the 17th century. It was taken by Llewellyn the Great, Prince of North Wales, in 1215, during the disturbances between King John and the barons; and in 1403, Henry IV. here defeated the insurgent Percies and their allies with great slaughter. It was taken by the Parliamentarians in 1644.

SHRIKE or BUTCHER-BIRD (*Lanius*), a genus of birds of the family *Laniadæ* (q. v.), approaching more nearly in character to the *Falconidæ* than any other of that family; having a short, thick, and compressed bill, the upper mandible curved, hooked at the tip, and furnished with a prominent tooth, the base of the

Great Gray Shrike (*Lanius excubitor*).

bill beset with hairs, which point forwards. The species are numerous, most of them natives of warm climates, although some occur in the more northern parts of the world. They prey on insects and small birds, and have a remarkable habit of impaling their prey on thorns; so that the nest of a S. may be discovered by the numerous insects impaled in the neighborhood of it. Shrikes kill and impale many insects which they never eat, leaving them to dry in the sun; and in confinement they make use for this purpose of a nail, if provided with it, or stick portions of their food between the wires of the cage. They can imitate in some degree the notes of many birds, particularly those which are the utterance of distress, and they seem to make use of this power in order to attract birds within their reach. The most common British species, rarely seen, however, except in the south of England, is the RED-BACKED S. (*L. Collurio*), a bird only about 7¼ inches in length, about a third of the length being formed by the tail, which is square at the end. Insects are the chief food of this bird, but it also preys on small birds, young frogs, and even young pheasants.

The GREAT GRAY S., or SENTINEL S. (*L. excubitor*), is about the size of a thrush. It is a rare bird in Britain, but common in some parts of Europe, and is found also in Asia and North America. It was formerly used by falconers in catching hawks, of which it is greatly afraid, screaming loudly on their approach: the falconer waited in concealment, after fastening some pigeons and a S. to the ground, until the scream of the S. gave him notice to pull the string of his net.

SHRIMP (*Crangon*), a genus of crustaceans, of the order *Decapoda*, suborder *Macroura*, and family *Crangonidæ*, allied to lobsters, crayfish, and prawns. The form is elongated, tapering, and arched as if hunch-backed. The claws are not large, the fixed finger merely a small tooth, the movable finger hook-shaped. The beak is very short, affording a ready distinction from prawns. The whole structure is very delicate, almost translucent; and the colors are such that the creature may really escape observation, whether resting on a sandy bottom, or swimming through the water. The quick darting movements of shrimps, like short leaps, however, betray them to any one who looks attentively into a pool left by the retiring tide on a sandy shore. When alarmed, they bury themselves in the sand, by a peculiar movement of their fanlike tail fin.—The COMMON S. (*C. vulgaris*) is very abundant on the British coasts, and very generally elsewhere on those of Europe, wherever the shore is sandy. It is about two inches long, of a greenish-gray color, dotted with brown. It is in great esteem as an article of food, and is generally taken by nets in the form of a wide-mouthed bag, stretched by means of a short cross-beam at the end of a pole, and pushed along by the shrimper wading to the knees. Sometimes a net of larger size is dragged along by two boats. The supply of the market with shrimps affords employment to a great number of people.—The other species of S. seem to be equally fit for the table. Several are occasionally taken on the British coasts, but belong rather to more southern climates. Shrimps are very interesting inmates of the aquarium.

SHRO'PSHIRE, or SA'LOP, a frontier county in the west of England, bounded W. by North Wales, and E. by Stafford and Worcester. Area, 841,167 acres; pop. (1871) 248,111; (1881) 247,993. The Severn, the principal river, enters the county from Montgomeryshire, about 12 miles west of Shrewsbury. It pursues a generally south-east course of 70 miles across the county, is navigable throughout, and is joined by two considerable trib-

utaries, the Tern and Teme. To the north and north-east of the Severn, the country is generally level, and is under tillage; to the south and south-east, it is hilly and mountainous, and here cattle-breeding is extensively carried on. A breed of horned sheep is peculiar to this county. More than three-fourths of the whole acreage are arable, or in pasture and meadow. The soil is generally fertile and well cultivated, though there are still extensive tracts of waste land. S. is remarkable for its mineral wealth. The coal, iron, copper, and lead fields of Coalbrookdale, Snedshill, Ketly, &c., are very productive. Several thousand persons are employed in raising coal, iron, stone, and lime, and in the iron manufacture. The county returns four members to the House of Commons. Capital, Shrewsbury.

SHROUDS are very strong ropes passing from the heads of the lower masts in a ship to the chains or channels on her sides, for the purpose of affording lateral support. They are crossed by thinner ropes, called ratlines, to form steps or ladders. The top-mast shrouds in ship-rigged vessels are similar, except that they terminate in a row of dead-eyes on the outside of the tops.

SHRO'VETIDE (Anglo-Saxon *scrifan*, to shrive, to confess) literally means 'confession-time,' and is the name given to the days immediately preceding Ash-Wednesday, which, as indeed the whole period after Septuagesima Sunday appears to have been, were anciently days of preparation for the penitential time of Lent; the chief part of which preparation consisted in receiving the sacrament of penance, i. e., in 'being shriven,' or confessing. In the modern discipline of the Roman Catholic Church a trace of this is still preserved, as, in many countries, the time of the confession, which precedes the paschal or Easter communion, commences from Shrovetide. These days were sometimes called Fasting-tide or Fast-mass, names which are still retained among the population in some parts of great Britain. The name of S. was retained in England after the Reformation, although the practice of 'shriving,' in which it had its origin, was abandoned. The precept of 'shriving' having been fulfilled, the faithful, upon the eve of entering upon the Lent, were indulged with permission to give themselves up to amusements, and to festive celebrations, of which the counterpart is still seen in the continental carnival. In England, the pastimes of football, cock-fighting, bull-baiting, &c., were, down to a late period, recognized usages of S.; and the festive banquets of the day are still represented by the pancakes and fritters from which Pancake Tuesday took its name, and by the 'collops' which gave its title to Collop Monday. These usages are gradually disappearing.

SHRUB (see SYRUP), a kind of liqueur made chiefly in the West Indies. It consists of lime or lemon-juice and syrup, to which a small portion of rum is added; other flavoring materials are used occasionally.

SHRUBS are plants with woody stem and branches like trees, but of smaller size, not generally exceeding 20 feet in height, and branching near the root, so as to have no main stem of considerable height. When a shrub is of small size and much branched, it is often called a *bush*. There is no more important botanical distinction between trees and shrubs, and the same genus very often includes species of both kinds. Many shrubs, as honeysuckle, are climbers.

In point of Law, whoever plants a shrub thereby makes it part of the soil, and it becomes a kind of fixture, incapable of being removed by tenants. But if the tenant is a nurseryman, who makes a business of planting and removing shrubs, it is otherwise. Whoever unlawfully and maliciously cuts, breaks, barks, or roots up a shrub growing in a pleasure-ground, garden, or ground adjoining a dwelling-house, if the injury exceed one pound in value, is guilty of felony, and liable to penal servitude for three years; and wherever the shrub is situated, if the damage amount to one shilling, the person is liable to be imprisoned or fined by a justice of the peace.

SHUGSHU'T, a small town of Turkey in Asia, in Anatolia, on the left bank of the Sakaria, 95 miles in direct line south-east of Constantinople. On an adjacent hill is the tomb of Othman (q. v.), founder of the Ottoman dynasty. The tomb, resembling the handsomest and most ancient of the Turkish sepulchres at Constantinople, stands amid a grove of cypresses and evergreen oaks. Pop. estimated at about 8000.

SHUMALA'RI. See HIMALAYA.

SHU'MLA, a city of Bulgaria, about half-way along the line of railway which connects Rustchuck and Varna, and 60 miles S. S.W. of Silistria. It is bounded on the north and west by mountains, and on the south and east by an undulating plain furrowed by valleys that extend north to the Danube. Its situation is pleasing, and the character and distribntion of its buildings give it a picturesque appearance. The roads from the former Turkish fortresses on the Lower Danube and in the Dobrudscha on the north, and from the passes of the Eastern Balkan on the south, converge upon S., and for this reason it is an important strategic position. Under the Turkish sway, S. was one of their most important strongholds, with very strong and extensive fortifications, and possessed a citadel, arsenal, capacious magazines, large and numerous barracks, and a military hospital. The plain around was also studded with detached forts. In S. are nearly 40 mosques. Wine and silk are largely produced; there are manufactures of copper, tin, and leather. The inhabitants during the Turkish supremacy were estimated at about 20,000, and were for the most part Turks or Mohammedans. S. was attacked in vain by the Russians in 1774, in 1810, and in 1828. The Congress of Berlin, which established Bulgaria as an autonomous principality in 1878, resolved that the fortifications of S. and other Bulgarian towns should be destroyed.

SHUNT SYSTEM OF RIFLING is a very ingenious arrangement for securing the accurate centering of a projectile discharged from a rifled cannon. To obtain precision of aim and range, it is absolutely essential that the axis of a projectile should, at the moment of discharge, coincide exactly with the axis of the bore. This can scarcely be obtained unless the shot fits with extreme tightness into the gun; and if it does so, and the gun is a muzzle-loader, it is scarcely possible to load it. The ordinary principle has the projectile smaller than the bore, so as to pass readily into the gun, resting, of course, on the bottom of the bore. The projectile is covered with a soft metal, as lead, which expands with

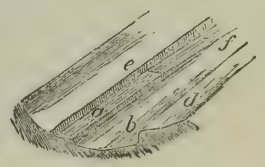


Fig. 1.

the pressure behind, and fits the shot tight into the grooves; but from the fact that it rested (at the commencement of the expansion) on the bottom of the bore, the axis of the shot is always below the axis of the bore. To obviate this, Sir William Arm-

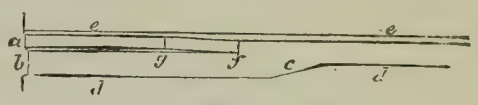

Fig. 2.

strong designed the 'shunt' system, which in some respects was found admirably effective. In rifling the gun, the groove for 14 inches from the muzzle consists of a wide, deep indentation (*b* in figs. 1 and 2), and at the side of it a narrow indentation of less

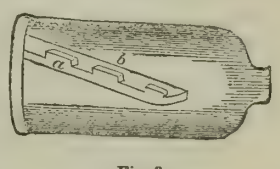

Fig. 3.

depth, *a*; from 14 inches to 22 inches from the muzzle, this narrow groove gradually deepens, till it attains the level of the broad groove, after which they run together for a short distance, until a shunt at *c*, fig. 2, narrows the whole groove on the same side as *a* to the original width of *b*. Projecting from the shell (fig. 3) is an iron flange *a*, too high to pass the narrow groove, and still higher, by its side, a narrow band of zinc or of brass studs, *b*. Each of these passes freely along the broad deep groove of the bore.

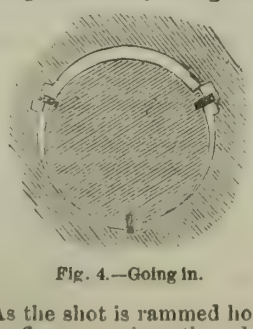

Fig. 4.—Going in.

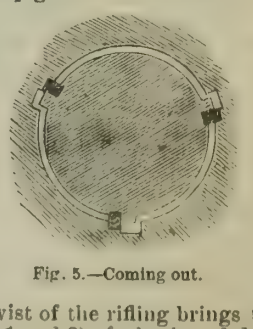

Fig. 5.—Coming out.

As the shot is rammed home, the twist of the rifling brings the iron flange against the edge *d* (figs. 1 and 2) of the broad deep groove, which enables both the flange and zinc band to pass freely until past *f* (fig. 2), where the inclined plane ends. At *c*, however, where the groove becomes narrowed to only the width of the flange and band together, the shot is shunted over to the left. In this position it is rammed home. In coming out, of course, the

pressure of the twist is reversed, and the zinc band presses against the straight edge *e*; on reaching *f*, the force of the exploded powder behind drives the shot on, while the inclined groove from *f* to *g* flattens down the zinc band, so that the projectile ceases to lie on the bottom of the bore, and is firmly centered by its several bands on the shallow grooves (whatever their number may be) round the bore's circumference. The lead fitting at the back of the shot has been meanwhile driven by the explosion into the deep wide grooves, so as to stop windage.

The sections of the muzzle in this article, figs. 4 and 5, are necessarily exaggerated in regard to the position of the shot, to show the principle. In reality, there is only a minute difference between the diameters of bore and projectile.

The shunt system having been found to be complicated, and liable to damage projectile and gun, was superseded in 1865 by the Woolwich system, a modified form of the French rifling (for which see RIFLED ARMS).

SHU'SHA, or SCHUSCHA, a fortified town of Russian Transcaucasia, in the government of Elisabetpol, and 120 miles south-west of the town of Schemacha. It was founded by Nadir Shah, and occupies a strong position on a mountain, accessible only on one side. Pop. (1880) 24,500.

SHU'STER, a city of Persia, in Khuzistan, on the Karun, 30 miles east-south-east of Dizful, at the foot of a range of sandstone hills. In the early part of the present century, it was an important town and the capital of the province; but it was nearly depopulated by an epidemic in 1832, and was much damaged by an inundation in 1840. On a height stands the castle, commanded, however, by a loftier elevation. The walls have been allowed to fall, and a fourth part of the town is in ruins. Customs are collected here, but the trade is not extensive. Pop. about 8000.

SHUTTLE, the instrument used to carry the weft-thread in weaving. See LOOM.

SIA'LOGOGUES are substances which, by local stimulating action, increase the secretion of saliva. Amongst the substances which thus act as direct stimulants to the Salivary Glands (q. v.), we may especially mention Horse-radish root, Mezereon bark, and Pellitory-root. Horse-radish root when chewed, produces a copious flow of saliva, and has been found useful in aiding deglutition in cases of paralysis of the tongue. If Mezereon bark is used in the same way, the saliva should be frequently ejected, in consequence of the acrid properties which it absorbs from the drug. Pellitory root is the best of this class of remedies. Fragments weighing from half a drachm to a drachm may be frequently chewed when we wish to increase the flow of saliva in cases of facial neuralgia, rheumatism of the muscles of mastication, and paralysis of the tongue.

SIA'M (native name *Thái* = the Free, or *Muang Thái* = the Kingdom of the Free), the chief state of Indo-China, is bounded on the S. by the Gulf of Siam and the Malay Peninsula. On the W., N., and E., the frontier line is ill defined and fluctuating, owing to many tribes being only partially under subjection, and to the constant wars of aggrandizement between S. and the Malayan and Burmese races on the west, and the Cambodian and Cochin-Chinese races on the east. According to a recent account, the country lies in lat. 4°—21° N., long. 96°—102° E.; is 1200 miles in length, and about 350 miles in extreme breadth. Area estimated at from 190,000 to 290,000 sq. m.; pop. stated at from 6,000,000 to 10,000,000. The kingdom consists of 41 provinces, each governed by a Phraya or functionary of the highest rank. There are numerous districts beyond the limits of the kingdom proper, as the Layos, Malayan, and Cambodian dependencies, which are more or less under subjection to S., and pay tribute generally once in three years. S. itself pays tribute to China, but only as a matter of usage and convenience, for it receives from that country more than a return, in the remission of duties upon Siamese vessels bound to Chinese ports. Cambodia is situated between S. on the west and Cochin-China, and as sovereignty over it is claimed by both these countries, and as it is too feeble to resist the claims, it pays tribute to both.

Surface, Hydrography, Coast-line, Soil, and Climate. — The mountains which cover the northern districts of the country, and form natural barriers along its east and west frontiers, are branches of the great system of the Himalaya. Though the northern dependencies of S. are mountainous, the kingdom proper is a vast plain, which only becomes hilly on its northern frontier. The great river of the country, the Nile of S., is called by foreigners Menam, or more commonly Meinam; but the Siamese call all rivers by this name, and distinguish the river by adding to the name Menam the name of the chief town or village on its banks; thus, Menam Bangkok is the river of Bangkok, that is, the great river of the country, which Europeans and other foreigners have agreed to call Meinam. This river, the great life-sustaining artery of the country, rises among the mountains of the Chinese province of Yunnan, whence it flows south, and after a course of more than 800 miles in this direction, throws itself by three mouths, which are from 6 to 8 fathoms deep, into the Gulf of Siam, about 30 miles (18 miles in direct line) below Bangkok. It receives a number of important affluents, notably the river Phitsalok, which joins it in lat. about 17° 35′ N. The annual inundation of the Meinam, the occasional non-occurrence of which entails failure on a great portion of the rice-crops, commences in June, and ends in November. Impregnated with the rich soil which it brings from the interior, its waters, in August, overflow the banks to a height sometimes exceeding six feet above the ordinary level. The tract of country within the direct influence of the inundations is estimated at 12,000 sq. m.; but, properly speaking, the actual valley of the Meinam, commencing 450 miles above the mouth of that river, and with an average breadth of 50 miles, has an area of upwards of 22,000 sq. m., and forms a tract of country the fertility of which is not exceeded in any other quarter of the globe. Of the other great rivers, the chief is the Mei-kong, which flows through the eastern districts of the empire, and is said to be 1600 miles long. The coast-line, fringing the edge of the Gulf of Siam, may be roughly estimated at 1100 miles, exclusive of minor windings.

The principal ports on the coast-line are Paknam (pop. 6500), defended by three forts; Paklat, a few miles above Paknam (pop. 7000), defended by a fort on each side of the river; Meklong, at the mouth of the river of the same name, long. 100° 10′ E., a beautiful city, with floating bazaars, fine pagodas and gardens, and a pop. of 10,000; Chantaburi, long. about 103° E., near the mouth of a river which, though short, fertilizes with its inundations a considerable district, a place of active trade with China and Cochin-China, with a pop. of 6000; and Bangplasoi, 27 miles east-south-east of Paknam, engaged in a profitable fishery and in agriculture, pop. 6000. The breadth of the Malayan Peninsula, in lat. 11° N., is only 50 miles, and here two streams, the one flowing west to the Bay of Bengal, and the other east of the Gulf of Siam, offer great facilities for the construction of a ship-canal, for their sources being near each other, a few miles of canalization are all that would be required to connect them, and thus form a sea-way across the peninsula, which would shorten the voyage between India and Eastern Asia by many days, and often by weeks.—The climate of S. is, for a tropical region, salubrious; the resident missionaries speak highly in its favor. The mean temperature at Bangkok, for a series of eight years, was 81° 14′; the maximum heat, within the same space, was 97°, and the minimum 54°. Hurricanes and typhoons are almost unknown in S., though it is visited every year by the south-west and north-east monsoons —the former bringing clouds, thunder-storms, and rain, the latter bringing refreshing weather.

Agriculture, Flora, and Fauna.—In S., few of the instruments in use in scientific agriculture are known, and in many parts of the country, in 1855, the ground was prepared for the seed by turning herds of buffaloes into the fields to trample down the weeds and move the soil, and afterwards by harrowing the ground with thorny shrubs. But the soil here is so rich that the smallest outlay of capital and labor is awarded by abundant harvests. A much more advanced system of agriculture, however, has been introduced within recent years, and the quantity of agricultural products exported has greatly increased. Rice and sugar are the principal crops. Of the other products, the chief are *Aquila*, or eagle-wood, renowned for its perfume, and extensively used on that account at funerals, marriages, and other ceremonies in Eastern Asia; gutta-percha; cardamons; gamboge; bamboo; the rattan; valuable palms; the guava; mango; daurien, esteemed the king of fruits in S.; the mangosteen, and many other fruit and other trees, including teak and a variety of valuable ship and house timbers. Among the animals, the most famous is the elephant, which abounds in the forests. It is against the law of S. to kill elephants, as these animals are considered the property of the king; but many of them are nevertheless slain for the sake of their tusks. A variety of this animal, said to be pecular to S., is the white elephant, which is not really white, but of a light mahogany color. This animal is held in the highest veneration, the cause of which is, that he is 'supposed to be the incarnation of some future Buddha, and will therefore bring blessings on the country which possesses so great a treasure.' He is fed upon fresh grass, and sugar-canes and plantains, served in rich dishes, is covered with ornaments, inhabits a building attached to the palace, enjoys the rank of nobility, and is tended by a staff of officers, guards, valets, &c.

Tigers abound, especially in the Laos country in the north; tiger-cats, rhinoceroses, boars, wild pigs, elks, and deer of many kinds, tenant the woods. Crocodiles, lizards, and serpents of various kinds are numerous. Excellent fish are found on the coasts and in the rivers.

Minerals.—Gold is found among the mountains, and silver in combination with other metals; copper, tin, lead, and iron are abundant, and are extensively worked by the Chinese. Precious stones are found in great number and variety.

Manufactures.—Vases, urns, and other vessels, in the manufacture of which gold is embossed upon silver, are made here in great numbers, and have an oriental celebrity. Gold-beating, iron-founding, and manufactures of fine cloth, glass-wares, and pottery are carried on.

Commerce, Exports, and Imports.—In former times, Bangkok (q. v.), the capital, was the most commercial city east of the Cape of Good Hope, after Calcutta and Canton, and 60 British ships were engaged in trade with the river Meinam. But in 1855, such had been the influence of bad legislation, and such the destructive progress of monopoly, that the foreign trade had become reduced almost to nothing. Sir John Bowring, Her Majesty's Plenipotentiary, arriving in S., negotiated a treaty of friendship and commerce with the Siamese rulers (signed at Bangkok, April 1855), which provides that British subjects are permitted to trade freely in all the seaports of S., may purchase lands, houses, &c., and may profess the Christian religion undisturbed. By this treaty, all monopolies are rescinded, British traders purchasing directly from the producer, and selling directly to the purchaser, without the interference of any third party. Export duties are levied upon all goods that leave the country, but they pay one impost only, whether this be levied under the name of inland-tax, transit-duty, or duty on exportation.

Prior to 1856, the British arrivals amounted to only 12 per annum; in 1858, they amounted to 81 vessels; and in 1881, the entries at the port of Bangkok, which is the center of the foreign trade of S., included 268 British vessels (of a total of 524 vessels) of 110,625 tons. In the years 1876–80, the total exports had an annual value of from £1,600,000 to £2,200,000; the imports from £1,000,000 to £1,300,000. The trade with Britain fluctuates in an extraordinary manner. Exports to Britain vary from £20,000 to £340,000; imports from Britain, from £15,000 to £30,000. The chief articles exported were rice and sugar, and the principal imports of British goods were iron and machinery. These statistics are for the port of Bangkok alone. The public revenue is variously estimated at from £1,000,000 to £3,000,000; but in any case the tax collectors, who have only a nominal salary, appropriate fraudulently a large proportion of the total.

Inhabitants and Government.—The Siamese proper, that is, the Thái race, form about a third of the entire population. 'They are gentle, timid, careless, and almost passionless.' They differ in several respects from many eastern nations. Lying, though frequently resorted to as a protection against injustice and oppression, is not a national characteristic. The Siamese are inclined to be idle, inconstant, and exacting; but they are sincere, very affectionate in their domestic relations, witty in conversation, and, like the Chinese, expert in mimicry. About a third of the whole population are Chinese, who are great emigrants, but who, wherever they go, preserve their own language, customs, costume, habits, and social organization. There are, it is estimated, 1,500,000 Chinese in S.; in Bangkok alone there are 200,000. All the active business of the country is in their hands. The Laos people (see SHAN STATES) are also very numerous in the country, and there are considerable numbers of Malays and Cambodians.

The religion of the Siamese is Buddhism (q. v.), which inculcates the highest veneration for life in whatever form. A Siamese will not kill vermin or serpents; and the tameness of many creatures that in Europe flee from the presence of man, is observed by all strangers. The use of Betel (q. v.) is almost universal in Siam. All the *belles* of S. stain their teeth black. The Siamese are extremely ceremonious in their intercourse one with another. An inferior crouches and crawls on the ground before a dignitary, and speaks of himself as 'your slave—a hair—a little beast.' They are a small well-proportioned race, with olive-colored skin, and black hair, of which all that they allow to grow is a tuft about two inches long on the top of the head—the rest being shaven off. They are remarkably fond of jewelry and ornaments, and the dresses of the higher functionaries and nobles is splendid and beautiful. They are fond of music; have a number of good native instruments, as well as the common European ones, and are skilful performers.

The government is an absolute and hereditary monarchy, and there are two kings. The First King is the actual monarch; the Second King, who receives about one-third of the revenue, and has an army of 2000 men, seems to occupy the place of first counsellor, and is invariably consulted by the First King before any decisive step in the administration of affairs is taken. The present first king Phrabat Somdetja Phra Paramínthara, was born in 1823, and ascended the throne on his father's death, October 1, 1868. The second king, Kromam Bawarawichai Chau, son of the last named, succeeded his father in 1868. Since a decree of 1874 the king shares the legislative power with the Supreme Council of State and with his cabinet or Senabodi.

History.—The annals of the Siamese begin about five centuries B.C. But nothing authentic is known of the history of the country till 1350, in which year Ayuthia, the former capital, was founded. Cambodia was first conquered in 1532, and in this century the Siamese dominion extended to Singapore. The present dynasty ascended the throne in 1782. There have been numbers of Protestant and Catholic missionaries in S. since the year 1828, but so far as the Siamese are concerned, their labors have been almost if not altogether fruitless.—For further information on this most interesting country and people, see Bowring's *Siam* (Lond. 1857).

SIAM, GULF OF, an important arm of the Chinese Sea, is bounded on the N. and W. by Siam, on the S.-W. by the Malay peninsula, and on the N.-E. by Cambodia. At its entrance between Cambodia Point and the peninsula of Patani on the Malay Peninsula, it is 235 miles wide, and from the line drawn between these two points it extends inland in a north-west direction to the mouth of the Meinam, a distance of 450 miles. Four great rivers, navigable to a considerable distance from their mouths, and the chief of which is the Meinam (see SIAM), fall into the gulf. It is unvisited by hurricanes of any kind, and shipwrecks here are very rare.

SI'AMESE TWINS, a name given to two youths, Eng and Chang, born of Chinese parents in Siam, in 1811, having their bodies united by a band of flesh, stretching from the end of one breast-bone to the same place in the opposite twin. The survival to advanced life of such a *lusus naturæ* makes this one of the most remarkable cases on record. A union of the bodies of twins by various parts is not an unusual occurrence (see MONSTROSITY). Ambrose Paré has depicted instances of union by the back, belly, and forehead. The last occurred in two girls, who lived to the age of ten years, when one of them dying, a separation was made: the wound of the living girl assumed a bad character, and soon proved fatal. The Hungarian sisters, who lived about a century since, were united by the back, had one passage from the intestines, and each had one from the urinary organs. They died when they were 22 years of age. The Siamese twins were purchased of their mother at Meklong, a city of Siam, and were brought to America by Captain Coffin and Mr. Hunter in 1829. On examination, the connecting band seemed to have united them at first face to face, but constant traction had so changed its direction, that they stood partially side by side. Its length above was about two inches; below, nearly four; from above, downwards, it measured three inches; and its greatest thickness was one and a half inch. It was covered with skin, and when the center was touched, both felt it; but on touching either side of the median line, only the nearest individual was sensible of it. The connection between the Siamese twins presented many interesting points in regard to physiology and pathology, for although they formed two perfectly distinct beings, they appeared most frequently to think, act, and move as one individual.

After realizing a competence by the exhibition of themselves in the various countries of Europe, the Siamese twins settled in one of the southern states of America, where they were married to two sisters and had offspring. Owing to domestic quarrels, however, two houses were found necessary, each living with his wife a week at a time alternately. Ruined by the civil war in America, the Siamese twins again made the tour of Europe, and exhibited themselves to the public. They died in 1874, the one surviving the other an hour or two only.

For a full account of the structural peculiarities of such cases, see St. Hilaire's *Histoire des Anomalies de l'Organisation d'Homme et des Animaux.*

SIARA, properly, CEARA (q. v.).

SIBBALD, SIR ROBERT, an eminent Scottish naturalist, born at Edinburgh, 15th April 1641, of a good family (the Sibbalds of Balgonie, in Fife), studied at the High School and university of Edinburgh, and afterwards pursued his medical studies at Leyden, Paris, and Angers; settled as a physician in Edinburgh in 1662, devoted much time to botany and zoology, and aided Sir Andrew Balfour in establishing a botanic garden in Edinburgh. Having inherited an estate, he retired from medical practice, but continued his scientific pursuits; was appointed by Charles II. his Majesty's Geographer for Scotland, and was encouraged to prepare a work on the geography and natural history of his native country. His death is supposed to have taken place in 1722. He published many pamphlets on medical subjects, natural history, Scottish history, antiquities, &c. The work for which he is now chiefly remembered is his *Scotia Illustrata, sive Prodromus Historiæ Naturalis*, &c. (fol. Edin. 1684), a work of great merit for its time, but his *Collection of Several Treatises in Folio concerning Scotland, as it was of Old, and also in Later Times* (Edin. 1739), is not without value.

SIBE'RIA, a vast territory in Northern Asia, belonging to Russia. In England the name is generally applied to all the Russian possessions in Asia, with the exception of the Transcaucasian and Armenian provinces. Siberia so defined is bounded on the N. by the Arctic Ocean; on the E. by the seas of Kamtchatka, Okhotsk, and Japan, all of them arms of the Pacific

Ocean; on the W. by the Ural Mountains, Ural River, and Caspian Sea. The southern boundary is made to include the recent Russian acquisitions in Turkestan, runs from Lake Issyk Kul N. N. E., then eastwards by Kiahta to the Argun river, which it follows to the Amur; the latter it follows to long. 135° E., where it trends in a S. S. W. direction, ascending the Usuri tributary for 200 miles, and then runs straight to the sea at the northern frontier of Corea. In the official language of Russia, however, Siberia is not of so wide extent. The Russian possessions in Turkestan form a separate division under the name of CENTRAL ASIA, and to this portion of the empire the governments of Akmollinsk, Semipalatinsk, Turgai, and Uralsk are now attached. Geographically speaking, these governments belong to Siberia; as do also considerable areas east of the Ural Mountains, which for administrative purposes form part of the European governments of Perm and Orenburg. The following article deals mainly with the region officially termed Siberia; for the Russian possessions in the Turkestan territory, see ASIA, CENTRAL.

The following are the subdivisions or governments of Siberia:

Divisions and Provinces.	Surface in Eng. Sq. Miles.	(Pop. 1870).
1. The Eastern Seaboard	708,253	43,320
2. Amur-land	107,514	22,297
3. Yakutsk	1,500,141	231,977
4. Transbaikalia	210,799	430,780
5. Irkutsk	279,963	378,244
6. Yeneseisk	958,042	372,862
7. Tomsk	329,783	838,756
8. Tobolsk	565,920	1,086,848
Total	4,660,415	3,405,084

(With Central Asia, but excluding the Caucasus, the total area of Russian Asia is nearly 6,000,000 sq. miles, and the pop. 8,500,000). It thus appears that in Siberia Proper there are about three inhabitants to every four English sq. miles. The northern and eastern shores are very irregular in form, jutting out frequently into bold peninsulas and promontories, and being indented with numerous immense inlets, chief of which are the estuaries of the Obi (575 miles in length) and of the Yenesei; the Gulf of Anadir, and the Sea of Okhotsk. All the island groups to the north of S., and since 1875 the whole of Sakhalin or Saghalien on the east coast belong to Siberia; whereas, since 1875, all the Kurile Islands are Japanese. The Liakhoff group, near the mouth of the Lena, consists of three islands, from 60 to 100 miles long by 20 to 40 broad, and of numberless islets: they are completely barren, and present in their soil and subsoil alternate layers of sand and ice, in which are imbedded the remains of animals.

The northernmost point of Siberia and of the old world is Cape Chelyuskin, or North-east Cape. Professor Nordenskiöld, who in 1878—79 sailed along the whole coast of S. from east to west, found Cape Chelyuskin to be in lat. 77° 41′ N. A country of such vast extent as S. (greatly larger than Europe) must necessarily exhibit great varieties of climate; and we accordingly find in the northern regions, much of which lie far within the Arctic Circle, an extensive tract bordering on the ocean, composed of swamp, moorland, and mossy flats, covered with snow and ice for one half of the year, and even during the greatest heats of summer, released from its icy bonds only to the depth of a few inches below the surface of the soil. The ocean, its northern boundary, is frozen for miles seaward during more than half the year, and during the remaining months, the numberless icebergs and floes which crowd the sea, and continually come into collision, render the navigation so dangerous that no complete hydrographic survey of the coast has yet been made. On the southern boundary of this semi-barren zone, stunted misshapen bushes and trees are found; and as we advance southwards, vegetation appears in the form of extensive forests of birch, fir, and larch, which clothe the plains and hill-sides, and are interspersed with stretches of pasture of moderate quality. After crossing the parallel of lat. 64° N. in West S., and that of lat 61° N. in East S., the more hardy cereals, barley, oats, and rye, begin to appear, and the soil increases in fertility, sometimes to an extraordinary extent, thick woods of Siberian cedar and other trees clothe the mountain sides, and the valleys, especially along the banks of rivers, are in a state of continuous cultivation.

The whole of Western S. is one great plain, sloping from its southern boundary, where the average elevation is 2000 feet, northwards to the Arctic Ocean; with the exception of the small corner in the south-west, which is drained into the Caspian and Aral Seas. The fertility of a great portion of the governments of Tobolsk and Tomsk, especially of the *Baraba* and *Ishim* steppes, is proverbial, and they are the great granaries of Russia and Northern Europe. But the warmest and perhaps most fertile part of Western S. is the valley of the Yenesei, north of the Sayansk Mountains. Eastern S. is more hilly and less fertile than the western portion, but the valleys and hill-sides afford good pasture. Four-fifths of S. is drained by the three immense rivers Obi (q. v.), Yenisei (q. v.), and Lena (q. v.), and by a number of smaller rivers, all of which flow to the Arctic Ocean. S. has a large number of lakes, some of which are little else than salt marshes; the largest of them are Lake Baikal (q. v.) and Lake Balkash (q. v.). The chief mountain-range of S. is the Altai chain, which forms the southern boundary towards Mongolia, and ramifies eastwards and northwards from the region of Lake Baikal, covering a large portion of the surface of Eastern Siberia. East of Baikal, the continuation of the Altai is rather a lofty tableland, running to Behring Straits, with many nearly parallel ridges; this plateau is the 'Great Divide' between the Lena and the Amur. The best defined and loftiest range is the Yablonovoi Mountains, or section of the Stanovoi Mountains, culminating on the frontier in a peak 8370 feet high. Farther east is the Stanovoi proper. Lofty mountain-chains traverse the island of Saghalien and the peninsula of Kamtchatka, in which there are 21 active volcanoes, the loftiest of which is Kliutshewsker: elevation, 15,000 feet.

Among the wild animals of S. are the reindeer in the northern flats, and on the high mountains of the south; the arctic or black fox, and white bear in the north; the sable, ermine, marmot, marten, squirrel, Caspian antelope, and wild sheep—all in the south; and the lynx, wolf, wild-boar, and glutton are generally diffused. Camels are found among the Kirghiz, along with the broad-tailed sheep, the Russian sheep being also domesticated in S.; and horses of good quality, an inferior sort of cattle of the Russian breed, and a large wolfish-looking dog, used chiefly to draw sledges, complete the list of domestic animals. Fresh and salt water fish abound, and feathered game is plentiful in the south. The mineral wealth of S. is great: gold, silver, copper, and lead are found in all the mountainous districts on the west and south; platinum, iron, and precious stones, including diamonds, are found on the eastern slopes of the Ural; zinc, antimony, arsenic, plumbago, and valuable emerald and topaz mines are worked in the districts north of the Amur; and porphyry, malachite, jasper, and salt (from the steppes) are common. The great majority of the inhabitants of the central and western provinces are Russians and Poles, or of Russian and Polish descent, and these have been sent to the country either as exiles, on account of political or criminal offences, or as government colonies. The most abandoned class of exiles are kept to hard labor in the mines; others are put to less laborious, but still compulsory work; and a third portion are settled in specified districts, under surveillance of the police, and allowed to employ themselves as they choose. This last class chiefly employs itself in trapping those animals whose skins and furs form valuable articles of trade.

In the north-west are found the Samoieds, and adjoining them the Ostiaks, both of whom live by hunting and fishing alone. In the south are the nomad tribes of the Kirghiz (q. v.) and Kalmucks (q. v.), both cattle-breeding peoples, though the latter have now partially adopted a settled mode of life, and manufacture iron and gunpowder. Next to them, on the borders of Manchuria, are the Buriats, a people of Mongol origin, and the most numerous tribe in S.; to the north of whom are the Yakuts and Tunguses, of Tartar origin, who are spread over the whole of Eastern S., from the town of Irkutsk to the Stanovoi range; and live mostly by hunting. The Tchuktchis, an Esquimaux race, and the Koriaks inhabit the north-east corner, and the Manchus are the population of the Amur territory. Manufactures are unimportant, and are confined to the principal towns; the barter trade in European goods is carried on at Obdorsk, Ostrovnoe, Yakutsk, and Petropavlovsk; and the transit-trade with China through Kiahta (q. v.), the imports from China being tea of the finest quality, sugar, silk, cotton, wool, grain, fruits, &c.; and the exports to that country, cotton and woollen cloths, linen, furs and skins, leather, and articles of gold and silver. The exports to Russia are the natural produce of the country, and are transported westward to the frontier by alternate land and river carriage, to Tobolsk, thence over the Ural Mountains to Perm. Reindeer sledges are the usual means of transport in winter. Fairs are held at stated periods in certain localities, and much of the trade of the country is there transacted.

The chief towns in Siberia Proper are Tobolsk, pop. 20,000; Tjumen, 13,000; Tomsk, 24,000; Irkutsk, 27,000. S. seems to have been first made known to the Russians by a merchant named Anika Stroganoff; and soon after, the conquest of Western S. was effected by the Cossack Vassili Yermak, an absconded criminal, at the head of a numerous band of wild followers. After Yermak's death in 1584, the Russians pursued their conquests eastward, founding Tomsk in 1604, and though they often experienced serious reverses, their progress was rapid, the Sea of Okhotsk being reached in 1639, and Irkutsk founded in 1661. Frequent disturbances have occurred between the Russians and the Chinese and Tartars, which have resulted in the extension southward of the Siberian boundary into Manchuria and Turkestan (q. v.). In 1845 the left bank of the Amur became Russian.

In 1858 the frontier was extended along the sea-board south of the river to the frontier of Corea. The Russians have now a large number of steam-vessels on the Amur. Recent voyages of exploration point to the practicability of opening direct and extensive commerce between Archangel and the rivers Obi and Yenesei. The Lena is also navigable for a great distance from its mouth. During the last 250 years, above 1,000,000 exiles have gone to S., if we include women and children accompanying their banished relatives. The yearly average is 8000 or 9000. Accounts as to their treatment vary greatly; some affirming that all are fairly used; some, that they, even political exiles, are very harshly dealt with. The manufacturing industries of S. are developing slowly; its mines are extensively wrought; but agriculture is practised only by the Russian settlers.—See Atkinson's *Siberia* (1858); Eden's *Frozen Asia* (1880); Lansdell's *Through Siberia* (1882); 'Asia' in *Stanford's Compendium* (1882).

SI'BYL (Gr. *Sibulla;* etymology doubtful), the name anciently given to several prophetic women, whose history has come down to us in a wholly mythical form. Their number is differently given; some writers (Ælian, for example) mention only four—the Erythræan, the Samian, the Egyptian, and the Sardian; but in general ten are reckoned, viz., the Babylonian, the Libyan, the Delphian, the Cimmerian, the Erythræan, the Samian, the Cumæan, the Trojan or Hellespontian, the Phrygian, and the Tiburtine. Of these, by far the most celebrated is the Cumæan, identified by Aristotle with the Erythræan, and personally known by the names of Herophile, Demo, Phemonoë, Deiphobe, Demophile and Amalthæa. She figures prominently in the 6th book of Virgil's *Æneid*, as the conductor of the poet into the realm of the shades. The Roman legend concerning her (as recorded by Livy) is, that she came from the east, and appearing before King Tarquin the Proud, offered him nine books for sale. The price demanded appeared to the monarch exorbitant, and he refused to purchase them. She then went away, destroyed three, and returning, asked as much for the remaining six as for the nine. This was again refused, whereupon she destroyed other three, and once more offered to sell him the rest, but without any abatement of the original price.

Tarquin was struck by her pertinacity, and bought the books, which were found to contain advices regarding the religion and policy of the Romans. They were preserved in a subterranean chamber of the temple of Jupiter on the Capitoline, and were originally intrusted to two officials (*duumviri sacrorum*), appointed by the senate, who alone had the right to inspect them. The number of keepers was afterwards increased to 10 (*decemviri*), and finally, by Sulla, to 15 (*quindecemviri*). In the year 84 B.C., the temple of Jupiter having been consumed by fire, the original Sibylline books or leaves were destroyed, whereupon a special embassy was despatched by the senate to all the cities of Greece, Italy, and Asia Minor, to collect such as were current in these regions. This being done, the new collection was deposited in the temple of Jupiter after it had been rebuilt. Spurious Sibylline prophecies—or what were regarded as such—accumulated greatly in private hands towards the close of the Republic; and Augustus, fearing, perhaps, that they might be turned to political uses, ordered them all to be given up to the city-prætor, and burned them. More than 2000 were destroyed on this occasion. The remainder were kept in the temple of Apollo, on the Palatine, under lock and key; but the whole perished during the burning of Rome in the time of Nero. Other collections were made; and as late as the 6th c., when the city was besieged by the Goths, there were not wanting some who pretended to predict the issue from a consultation of these venerable oracles. It is, however, beyond doubt, that as early, at least, as the 2d c. A.D., when enthusiastic men sprung up in the Christian church, prophesying in a poetic-oracular style (whence they were sometimes called *Sibyllists*), the Sibylline books were much interpolated and falsified to assist the progress of the new faith. The utterances of these Christian Sibyllists form a special department of early ecclesiastical literature, and are a mixture of Jewish, Pagan, and Christian ingredients. The collections of them also bear the name of 'Sibylline Books.' An edition of the *Oracula Sibyllina* was published by Gallæus in 1689.—See works on the Sibylline Books by Bleek (1819), Volkmann (1853), Ewald (1858).

SICI'LIAN VE'SPERS, the name given to the massacre of the French in Sicily, on the day after Easter (March 30) 1282, the signal for the commencement of which was to be the first stroke of the vesper-bell. In the articles NAPLES, KONRADIN, MANFRED, &c., it is related how Charles of Anjou, the brother of Louis IX. of France, had deprived the Hohenstaufen dynasty of Naples and Sicily, and parcelled out these kingdoms into domains for his French followers; but his cruelty towards the adherents of the dispossessed race, his tyranny, oppressive taxation, and the brutality of his followers, excited among the vindictive Sicilians the deadliest animosity. The aged Giovanni da Procida, a steady partisan of the Hohenstaufen family, took the lead in directing and systematizing a conspiracy against Charles and his followers; and after a visit to Pedro of Aragon (the husband of Constance the cousin of Konradin, and the next heir to Naples and Sicily), whom he found willing to undertake the conquest of Sicily, he returned to his self-imposed duty in the island. On the evening of Easter-Monday, the inhabitants of Palermo, enraged (according to the common story) at a gross outrage which was perpetrated by a French soldier on a young Sicilian bride, precipitated the accomplishment of the scheme by suddenly rising upon their oppressors, putting to the sword every man, woman, and child of them, not sparing even those Italians and Sicilians who had married Frenchmen. This example was followed, after a brief interval, by Messina and the other towns, and the massacre soon became general over the island; the French were hunted like wild beasts, and dragged even from the churches, where they vainly thought themselves secure. More than 8000 of them were slain by the Palermitans alone.

Only one instance of mercy shown to a Frenchman is on record. The governor of Messina also succeeded in passing the strait with his garrison before it was too late. The 600th anniversary of the Sicilian Vespers was celebrated with much enthusiasm in 1882, Garibaldi (shortly before his death) having come to Palermo on purpose to be present. He was, however, too feeble to take part in the ceremonies.—See Amari, *La Guerra del Vespro Siciliano.*

SICILIA'NA, in Music, a name given to a slow, soothing, pastoral description of air, in $\frac{6}{8}$ time; so called because the dance peculiar to the peasantry of Sicily possesses this character.

SI'CILY, the largest, most fertile, and most populous island in the Mediterranean Sea, lies between lat. 36° 38′—38° 18′ N., and between long. 12° 25′—15° 40′ E., and is separated from the mainland of Italy by the Strait of Messina. Its shape roughly resembles a triangle (whence the early Greek navigators gave it the name of *Trinacria*, the ('Three-cornered')—the eastern coast, from Capo del Faro in the north to Capo Passaro in the south, forming the base; and the northern and south-western coasts the sides which gradually approach each other towards the north-west. The length of the base is 145 miles; of the northern side, 215 miles; and of the south-western, 190 miles: the circumference of the island, including the sinuosities of the coast, is estimated at 624 miles. Area about 10,000 sq. miles. Pop., at the census of 1871, 2,584,099; of 1881, 2,928,840. Capo Passaro, at the south-eastern extremity, is only 56 miles from Malta; and Capo Boco, near Marsala, at the north-western, only 80 miles from Cape Bon on the African coast.

Physical Geography.—The island of S., like the mainland of Italy, is traversed throughout its entire length by a chain of mountains, which may be looked upon as a continuation of the Apennines (q. v.). This chain, beginning at Capo del Faro on the Strait of Messina, runs in a south-south-western direction as far as Taormina, where it turns off to the west, and stretches across the whole island, keeping, however, much nearer to the northern than to the south-western coast. The first part of the chain, from Capo del Faro to Taormina, is called the Peloric range (anc. *Neptunius Mons*), which in Monte Dinnamare attains the height of 3260 feet; the second and much the longer part is called the Madonian range (anc. *Nebrodes Montes*), which, in the Pizzo di Palermo, rises to an elevation of 6328 feet. It forms the great watershed of the island. Towards the north-western coast, the chain breaks up into irregular and often detached masses, such as Monte Pellegrino (1963 feet) and Monte San Giuliano (2184 feet). About the center of the chain, a range branches off through the heart of the island to the south-east; at first wild and rugged, but afterwards smoothing down into table-lands, which in turn slope away tamely to the sea. There are innumerable other spurs to the south from the great Madonian chain, of inferior length and elevation, but none of these require special mention.

The volcano of Etna, which rises in solitary grandeur on the eastern coast, is separately described. See ETNA. S. is not, on the whole, a well-wooded country, but forests of considerable size are found here and there—as, for example, the royal forests near Caronia and Mezzojuso, the forest-zone of Etna, &c.—In the interior of the island there is not much level land, but on several parts of the coast there are extensive plains, generally of great fertility. The principal of these are the great plain of Catania (anc. *Campi Leontini*) out of which rises Etna; the plains of Palermo, termed the *Conca d'Oro*, or 'Golden Shell,' of Castellamare, of Licata and Terranova.—Although rivers are numerous, none are navigable. The largest are the Simeto or Giarretta, the Cantara, the Salso, the Platani, and the Belici.

Climate.—The climate of S. is very warm, but salubrious, except in low-lying places, where there is a mephitic atmosphere. The best health is enjoyed in the lower region of Etna, which is very densely peopled, although exposed to eruptions and violent earthquakes. The heat is intense in summer when the sirocco blows. After the autumnal equinox, violent winds are prevalent, torrents of rain fall, and all along the coasts the atmosphere is

charged with moisture and fogs. The earthquakes begin about the end of winter, and do great damage. Snow and ice are rarely to be seen except on Etna.

Geology and Mineralogy.—The primary rocks in the mountainous districts are chiefly quartz, granite, and mica. In some parts these are overlaid by limestone rocks. Most of the lower ranges of hills are of calcareous formation, and are rich in metallic ores. Sulphur forms the chief mineral wealth of Sicily. Immense beds of it are found in the central and northern parts of the island. The English export about 42,000 tons of it per annum, and the mines are worked by Cornish miners and their descendants.

Soil, Agriculture, &c.—The soil of the island is so fertile that very little labor is required to raise the crops. In many valleys there is rich soil to the depth even of 40 feet. In Catania, decomposed lava is spread over the ground, greatly increasing its fertility. The crops of grain are large, and might be prodigious if agriculture were better understood; the harvests are such that they recall to mind the words of Livy, in speaking of S.: 'Populoque Romano, pace ac bello, fidissimum annonæ subsidium' (lib. xxvii. 5). In the most ancient times, agriculture was sedulously prosecuted, but it began to decline when the island was deprived of its independence by the Carthaginians. In more recent times, the restrictions on the exportation of grain served not only to keep agriculture from making any progress, but also to put a drag upon the commerce of the country, which, on every attempt made to raise itself, was met by fresh obstacles in the shape of new taxes. The Italian government has greatly alleviated the obstacles to agriculture, and the salutary effects of the change of system are already apparent. The soil produces corn, maize, flax, hemp; excellent cotton near Mazzara and in Catania; sugar, equal to that of the East Indies, along the southern coast; grapes (350,000 acres), olives (125,000 acres, with an annual yield in oil of 15,000 tons), saffron, oranges, lemons, citrons, pomegranates, figs, pistachios, dates, castor-oil, mulberry, sumach, tobacco, and manna. The vine has been cultivated with the greatest care at Marsala since 1789, when an English firm settled there began to export it. Now, upwards of 5,000,000 gallons are annually exported to England, America, and India.—S. possesses the best tunny-fisheries in the Mediterranean. The fisheries for coral at different places on the coast are also industriously carried on, and on an average, about 2100 lbs. are annually obtained.

Manufactures, Commerce, &c.—The manufactures of S. are insignificant, and are nearly altogether confined to silk, cotton, and leather.—The most important articles of export are sulphur, sumach, fruits, and wine; of import, cottons, woollens, silks, linens, earthenware, hardware. Great Britian, France, and the United States are the countries with which the Sicilians chiefly carry on commerce. The statistics of exports and imports are untrustworthy; but the latter considerably exceed the former. More than 200 miles of railways have recently been constructed.

Religion, Education, &c.—With the exception of about 58,000 Greeks, and a few thousand Jews, the inhabitants are all Roman Catholics; but though equally ignorant, they are not so superstitious as the Neapolitans; at least their superstition has not destroyed their love of political freedom, as has repeatedly been evinced in their history—most recently in the ardor with which they responded to the summons of Garibaldi to liberate themselves from the tyranny of the Bourbons. There are three universities—at Palermo, Catania, and Messina; and also a Collegio de' Nobilé at Palermo.

Political Divisions.—S. is divided into 7 provinces or prefectures—viz., Palermo, Messina, Catania, Noto or Siracusa, Caltanisetta, Girgenti, and Trapani. Each province is subdivided into 3 or 4 districts, and these again into numerous *communi* or 'townships.' Over the province is placed an *intendente*, or, as he is now called, a 'prefect;' over the district, a sub-prefect; and over the commune a *sindaco* ('syndic,' or 'mayor'). The prefect presides over every department of the provincial administration, and also over the provincial council—a body composed of from 15 to 20 landholders, who meet once a year, and sit for 20 days, examining the accounts of the province, and framing the provincial budget. The two surbodinate divisions have also their 'councils;' and the members of all three are appointed either by the king or by the prefect. Of course, this insular self-government does not supersede the necessity of sending Sicilian deputies to the national parliament at Rome.

History.—S. was inhabited, in pre-historic times, by a people who bore the name of *Siculi* or *Sicani*, and who—according to a universally received tradition—crossed over into the island from the southern extremity of the mainland. Their names and every fact that we can ascertain about them, lead to the supposition that they were members of the great Latino-Italian family that, entering Italy from the north, gradually pushed its way across the Apennines to the peninsula of Bruttium (see article Rome). Beyond this rational conjecture, however, we cannot proceed, and the actual history of S. only begins to emerge out of utter darkness with the establishment of Greek and Phœnician colonies.

The earliest Greek colony, that of Naxos, was founded 735 B.C.; the latest that of Agrigentum, 580 B.C. During the intervening century and a half, numerous important colonies were established (either directly from Greece or as offshoots from the older Greek settlements in the island); Syracuse (734 B.C.), Leontini and Catana (730 B.C.), Megara Hyblæa (728 B.C.), Gela (690 B.C.), Zancle, later Messana (date of origin uncertain), Acræ (664 B.C.), Himera (648 B.C.), Mylæ (date of origin uncertain), Casmenæ (644 B.C.), Selinus (628 B.C.), Camarina (599 B.C.), Agrigentum (580 B.C.). The earlier history of these cities is almost unknown. What is recorded is vague and general. We read that they attained great commercial prosperity, that they subjugated or wrested from the Siculi, Elymi, and other 'native' tribes large portions of neighboring territory; and that their governments (like those of the republics in the mother-country) were at first oligarchical, and latterly democracies or 'tyrannies;' but it is not till the period of the 'despots' that we have detailed accounts. Then the cities of Agrigentum and Gela acquire prominence — the former under the rule of Phalaris (q. v.), becoming for a short time, probably the most powerful state in Sicily; and the latter, under a succession of able tyrants, Cleander, Hippocrates, and Gelon (q. v.), forcing into subjection most of the other Greek cities. Gelon, however, transferred his government to Syracuse (one of his conquests), which now became the principal Greek city of Sicily—a dignity it ever after retained.

Contemporary with Gelon, and possessed of the same high capacity for governing, were Theron, 'tyrant' of Agrigentum, and Anaxilaus, tyrant of Rhegium, and conqueror of Zancle, to which he gave the name of Messana. Meanwhile, the Carthaginians—a people wholly different from the Greeks in language, religion, origin, and civilization—had obtained possession of the Phœnician settlements in Sicily. The first appearance of the Carthaginians in the island dates from 536 B.C.; but the steady growth of the Greek cities in wealth and power, long confined their rivals to the north-western part, where their principal colonies were Panormus, Motya, and Soloeis. The first open trial of strength took place in the great battle of Himera, where the Carthaginian army was utterly routed by Gelon, and its leader, Hamilcar, slain. The Gelonian dynasty at Syracuse fell 466 B.C., after experiencing various fortunes. During the next fifty years, the island had peace. In 410 B.C., however, the war between the Carthaginians and Greeks for the possession of the island was renewed. The successes of the former were great and permanent. Selinus, Himera, Agrigentum, Gela, and Camarina, fell into their hands in less than five years; and it was not till Syracuse had got a new 'tyrant,' the famous Dionysius (q. v.) the Elder, that fortune again began to smile on the Greeks. Even he, however, could not wrest from the Carthaginians what they had already won; and after the war of 383 B.C., a peace was concluded, which left Dionysius in possession of the eastern, and the Carthaginians of the western, half of the island.

The dissensions and tumults that followed the decease of Dionysius, illustrate forcibly the peculiar dangers to which the Greek republics, either at home or abroad, were prone; but we can only afford to notice the triumph of the popular party under Timoleon (343 B.C.), and the splendid victory of the latter over the Carthaginian generals, Hasdrubal and Hamilcar, at the river Crimisus, 340 B.C. Once more Greek influence was in the ascendant, but the rule of the bold and ambitious tyrant Agathocles (317—289 B.C.) proved in the main disastrous to Greek supremacy. After his death, Syracuse lost her hold over many of the Greek cities, which established a weak and perilous independence, that only rendered the preponderance of the Carthaginians more certain. Finally, Pyrrhus (q. v.), king of Epirus, was invited over to help his countrymen, and in 278 B.C. he landed in the island. The brilliant adventurer—one of the most romantic figures in classic history—for a time swept everything before him. Panormus, Ercte, and Eryx were captured; and though he failed to make himself master of Lilybæum, he might probably have forced the Carthaginians to surrender it, had he not been thwarted in his designs by the miserable discords and jealousies of the people whom he came to save. As it was, Pyrrhus left Sicily in about two years; and in all likelihood the island would have sunk into a Carthaginian possession, had not a new power appeared on the stage—viz., the Roman.

The struggle for supremacy between Rome and Carthage—the most tremendous struggle in ancient history—is sketched in the article Rome, and in the biographies of the leading generals, and therefore need not be narrated here. Suffice it to say, that in 246 B.C., Carthaginian S., and in 210 B.C., the whole island became a Roman 'province'—the first Rome ever held. Henceforth it shared the fortunes of the great state to which it was annexed, and its special history need only be rapidly glanced at. In 135—132 B.C., and again in 103—100 B.C., it was the scene of two formidable slave-insurrections, during which it was frightfully devastated. Its fertility, and the wealth of its citizens and landholders, were also powerful temptations to greedy and unscrupulous gov-

ernors, of whom we have a specimen in Verres (prætor 73—70 B.C.), 'damned to everlasting fame' in the Orations of Cicero. Augustus visited S., after the close of the civil wars, and established some colonies; but it does not seem to have prospered under the empire; and in 440 A.D. it was conquered by the Vandals under Genseric. The Vandals, in their turn, were compelled to cede it (480 A.D.) to Theodoric, king of the Ostrogoths, in whose hands it remained till 535 A.D., when Belisarius conquered and annexed it to the Byzantine empire. In this condition it remained till 827, when the Saracens invaded the island, and after a protracted struggle, lasting for 114 years, expelled the Byzantine Greeks, and made themselves masters of Sicily. They kept possession of it for upwards of a century, but after a contest of 30 years, were driven out by Robert Guiscard (q. v.) and Roger de Hauteville, at the head of a body of Normans, aided by the 'native' inhabitants, whom we conjecture to have been much the same as they were in the old classic times—for the successive waves of barbaric and Saracenic invasion that swept over the island, appear to have left little trace of their action.

Even to this day, it is highly probable that the people of S. are largely the descendants of the early Siculi. The Normans held rule in the island from 1072 to 1194; and the Norman 'Kingdom of Sicily and Naples,' or 'Kingdom of the Two Sicilies,' dates from 1130, when Roger II. obtaining possession of most of the continental dominions of his uncle, Robert Guiscard, assumed the title of king. During the rule of the Swabian dynasty (see HOHENSTAUFEN, HOUSE OF), 1194—1258, the political history of S. is the same as that of Naples; but in 1282, after the dreadful massacre of the French, known as the Sicilian Vespers (q. v.), it again became independent, chose for its king Pedro III. of Aragon, who was the sole representative by marriage of the House of Hohenstaufen, and remained in the possession of the Aragonese sovereigns till 1505, when the union of the crowns of Castile and Aragon—in other words, the rise of the Spanish monarchy in the persons of Ferdinand and Isabella, placed it under the dominion of Spain. The fortune of war also gave Ferdinand the possession of Naples; and the Spanish kings retained both countries until the war of the Spanish Succession, 1700—1713 (see SUCCESSION WARS). By the treaty of Utrecht (1713), S. was separated from Naples; and handed over to Victor Amadeus, Duke of Savoy, who, however, restored it to the crown of Naples by the treaty of Paris, seven years after, receiving in exchange the island of Sardinia. From 1720, the two countries continued under the same dynasty, the House of Austria, 1720—1734; and the Spanish Bourbons, 1734—1860 (if we except the brief rule of the French in Naples, 1806—1815, when Joseph Bonaparte, and afterwards Joachim Murat, were kings), down to the period of Garibaldi's invasion (see ITALY, and GARIBALDI), which resulted in the annexation of both to the new kingdom of Italy under Victor Emmanuel.

SICULIA'NA, a city of Sicily, province of Girgenti, and 8 miles west-north-west of the city of that name. It stands on the sea, and has a small, badly-situated harbor. Pop. 5764.

SI'CYON, the principal city of a very small but exceedingly fertile state of ancient Greece, Sicyonia, situated in the north of the Peloponnesus, having the Corinthian Gulf for its northern boundary, with Achaia on the W., Phlius on the S., and Corinth on the E. The territory was level towards the sea, somewhat mountainous in the interior, and well watered by the two rivers Asopus and Helisson, between which, on a triangular plateau, was situated S., about two miles south of the Corinthian Gulf, and ten north-west of Corinth. Round the three sides of the plateau ran a wall, which, combined with the precipitous nature of the heights that surrounded it, rendered the position of S. one of great strength. It is supposed that at one time it had, like Athens, a double wall reaching from the city to the port on the Sea of Corinth. S. was anciently celebrated as a chief seat of painting and statuary (tradition asserting that the former was invented there), it having given its name to a school of painting which included among its disciples Pamphilus and Apelles, both natives of Sicyon. It was also the native city of Aratus (q. v.), the general of the Achæan League. There exist at the present day a few remains of the ancient city, as well as of the more modern buildings erected by the Roman conquerors of Greece, near which stands a small modern village named *Vasilika*.

SIDA, a genus of plants of the natural order *Malvaceæ*, containing a large number of species, annual and perennial herbaceous plants and shrubs, mostly natives of warm climates, and widely diffused. They generally abound in mucilage, and some of them are used in medicine in India, as the Mallow and Marsh-mallow are in Europe. They have also strong pliable fibres, which are employed for cordage and for textile purposes.—*S. tiliæfolia*, an annual, has long been cultivated in China, where it is called *King-Ma*, for the sake of its fibre, which is used like that of hemp. It is too tender for the climate of Britain, but its cultivation has been introduced into Italy and France.

SIDDONS, MRS. SARAH, was the daughter of Mr. Roger Kemble, a provincial actor, and was born at Brecon, in South Wales, on July 5, 1755. As a mere child, she was brought on the stage on the occasion of a benefit of her father's; and from that time up to her 15th year, she continued to act as a regular member of his company. An attachment having sprung up between her and a young Mr. Siddons, an actor, with the somewhat reluctant consent of her parents, she was married to him at Trinity Church, Coventry, on 26th November 1773, and in company with her husband, went to act at Cheltenham theater. Here she speedily drew great attention; and Garrick, hearing her praises in London, sent to Cheltenham a trusty emissary to report upon her. The result was an engagement offered her at the London Drury Lane Theater, where, 29th December 1775, she made her first appearance, acting Portia in *The Merchant of Venice* to the Shylock of Mr. Garrick. Her beauty and fine person pleased the audience, but as an actress she made no great impression, and at the close of the season she failed to secure a re-engagement. It was considered that this was to some extent due to her having vexed the irritable vanity of Garrick, by an unintentional error in stage business, which made him act with his back to the public in one of his pet passages, a mortification which the great man was little enough to remember and resent.

Leaving London thus in failure in 1776, in 1782 she returned to it, to run a career of triumph as indisputably the greatest actress of her time. The intervening years she had passed in the exercise of her art on the stages successively of Birmingham, Manchester, York, and Bath, till the growth of her provincial reputation determined her recall to the metropolis. In 1784, her popularity was temporarily obscured by a calumny industriously circulated, which charged her with ungenerous and illiberal conduct towards certain of her fellow-performers; but with this trivial exception, till on the 29th June 1812, in her great character of Lady Macbeth, she took her leave of the public, her course was one long series of successes. Subsequently, she occasionally consented to reappear on the stage for charitable ends, or to promote a stage 'benefit,' in which she had a kindly interest. Her death took place in London, on the 8th June 1831.

As a tragic actress, Mrs. S. has probably never in this country been equalled; as a woman, she was of unblemished reputation, and enjoyed the respect of all who knew her. She was the ornament of every society into which she went, and such was the estimation in which she was held, that she had access at will to almost any. Her genius is said to have been strictly a *stage* genius; elsewhere, she seems to have been a woman of no extraordinary parts. But she had a certain way of making her mediocrities imposing. She carried her tragedy manners with her to the drawing-room or the dinner-table: Scott has recorded the amusement with which at Abbotsford he heard her stately blank verse to the domestic:

'I asked for water, boy! you've brought me beer;'

and Sidney Smith used to say, it was never without a certain awe that he saw her '*stab the potatoes.*'

SIDE-BONES are enlargements situated above a horse's heels, resulting from the conversion into bone of the elastic lateral cartilages, They occur mostly in heavy draught horses with upright pasterns, causing much stiffness, but, unless when of rapid growth, little lameness. They are treated at first by cold applied continually, until heat and tenderness are removed, when blistering or firing must be resorted to.

SIDE'REAL CLOCK, a clock so regulated as to indicate *sidereal time*. See DAY. The sidereal clock is a most important aid to the practical astronomer, and is one of the indispensable instruments of an observatory.

SIDERO'GRAPHY (Gr. *sideros*, iron). The name applied by the inventor, Mr. Dyer, to a process of printing with compound iron (or rather steel plates, for they are case-hardened after engraving) plates, instead of plain plates of copper or steel. It is the plan now usually employed in printing bank-notes in which more than one color is given. The colored parts of the design are cut out of the main plates, and movable pieces are exactly fitted in, so that they can be retracted or pushed forward at will. They are withdrawn whilst the main plate is receiving its ink, and they are pushed forward beyond whilst receiving their supply of ink. This being done, they are brought to one plane, and form a complete plate for printing from.

SIDERO'XYLON, a genus of trees of the natural order *Sapotaceæ*, having evergreen leaves and axillary clusters of flowers, natives of warm climates, and very widely distributed. They are remarkable for the hardness of their wood, which is sometimes called Iron-wood, and is at least in some species so heavy as to sink in water. The wood of *S. inerme*, called *Melkhout* at the Cape of Good Hope, is there much used for making boats, bridges, agricultural implements, &c.

SI'DI-BEL-A'BBÈS, a town of Algeria, in the province of Oran, and 50 miles south of the town of that name. It is fortified, and contains barracks, telegraph and post offices. Markets take place here every week. The soil in the vicinity is fertile; grain, tobacco, and fruit are the chief products. Pop. of commune, 6458.

SI'DLAW HILLS. See FORFARSHIRE and BIRNAM.

SI'DMOUTH, a market-town and watering-place on the south coast of Devonshire, at the mouth of the little river Sid. S. was a borough and market-town, governed by a port-reeve, as early as the 13th century. It was anciently a place of some importance as a fishing-town and seaport, but the fishery has declined, and the harbor is in great measure filled up with sand and shingle, so than it is now accessible to small boats only. The town has for many years past been a favorite watering-place, remarkable for the mildness and salubrity of its climate. The hills on each side of the valley of the Sid rise to a considerable height, and, where they terminate on the sea-coast, form bold and lofty cliffs, east and west of the town, known respectively as Salcombe Hill and High Peak, about 500 feet above the sea. Owing to the narrowness of the valley, the town presents no large frontage towards the sea; but the esplanade, protected by a sea-wall, 1700 feet in length, built in 1838 to stop the encroachment of the sea, forms an excellent promenade. Villas and detached houses extend for some distance inland, up the valley of the Sid, on both sides of the stream. The town is neatly, though irregularly built, lighted with gas, and paved, and contains baths, public rooms, &c. Pop. (1881) 3501. Some Roman remains have been found here. S. gives the title of viscount to the Addington family.

SIDNEY, SIR PHILIP, the son of Sir Henry Sidney, and Mary, sister to Robert Dudley, the favorite to Queen Elizabeth, was born at Penshurst, in Kent, on 29th November 1554. When ten years old, he was sent to school at Shrewsbury, whence, in 1569, he went to Christchurch, Oxford. From Oxford, he passed to Cambridge, which he left with a high reputation for scholarship and general ability. In 1572, as the custom then was for young men of rank, he went abroad on his travels. He was in Paris when the massacre of St. Bartholomew took place, and narrowly escaped being one of its victims. Thereafter, he visited Belgium, Germany, Hungary, and Italy; and in 1575, he returned home, perfected in all manly accomplishments. His uncle, Dudley, Earl of Leicester, was at this time in the zenith of his fortunes, and for S. a court-career lay temptingly open. As a courtier, his success was great; and with Queen Elizabeth he became, and continued while he lived, a special favorite. In 1576, as a mark of her approval, he was sent on an embassy to the court of Vienna, from which he returned in the course of the year following. Shortly after, he had the boldness to address to the queen a 'Remonstrance' against her proposed marriage with Henry, Duke of Anjou, a union to which she seemed herself not indisposed. It is significant of the high favor in which he was held by her, that Elizabeth, imperious as she was in temper, and little inclined to brook such interference, seems scarcely at all to have in this instance resented it. About this time, a quarrel with the Earl of Oxford led to S.'s temporary retirement from court, during which, at Wilton, the seat of his brother-in-law, the Earl of Pembroke, he wrote his celebrated *Arcadia*.

In 1583, he consoled himself for the marriage of Lady Penelope Devereux, to whom he had been ardently attached, and who figures as the Stella of his poems, by himself marrying Frances, the daughter of Sir Francis Walsingham. By this lady, he had one daughter, who survived him. In the spring of 1585, he is said to have meditated sailing with Sir Francis Drake in an expedition against the Spaniards in the West Indies, but to have been expressly forbidden by Elizabeth, on a ground of anxiety 'lest she should lose the jewel of her dominions.' It does not seem nicely consistent with this pretty story, that later in the same year she appointed him governor of Flushing, whither he went to take part in the war then being waged between her allies, the Hollanders, and the Spanish. As it proved, she thus sent him to his death. At the battle of Zutphen, in Gelderland, after behaving with conspicuous gallantry, and having a horse killed under him, he received a musket-shot in the thigh, and after lingering for some days in great suffering, he died at Arnheim, on the 7th October 1586, in the 33d year of his age. A beautiful trait of humanity is recorded of him as he was being borne wounded from the field. He complained grievously of thirst, and a bottle of water was procured for him, from which, as he was about to drink, he was touched by the wistful look up at it of a mortally wounded soldier, who lay close by, and taking it untasted from his lips, he handed it to his fellow in need, with the words: 'Thy necessity is yet greater than mine.' The estimation in which S. was held by his countrymen was shown in the passion of grief with which the news of his death was received. His body was brought to England, and after lying for some time in state, was buried with great solemnity in the old cathedral of St. Paul's, a general mourning on the occasion being observed throughout the country. The universities issued three volumes of elegies on his death, and Spenser, in his *Astrophel*, mourned for the loss of one who as a friend had been dear to him.

The love and admiration which S. won from his contemporaries was mainly a tribute to the singular beauty of his character. His short life was illustrated by no brilliant achievement; and his literary genius, though true and exquisite in its kind, would scarcely of itself have sufficed to account for the fervor of regard he inspired. But the purity and nobility of his nature, and the winning courtesies in which its gentle magnanimity expressed itself, took captive all hearts whilst he lived, and have since kept sweet his memory. 'Sublimely mild, a spirit without spot,' he lives in the history of his country, as a rare and finished type of English character, in which the antique honor of chivalry is seen shading into the graces of the modern gentleman. His *Arcadia*, overrun as it is with the fantastic affectations of the time, may still be recognized by the reader who has patience to peruse it, as a work of indisputable genius, flushed with the lights of a fine imagination, and in its purity and tenderness of sentiment, giving an authentic reflex of the lovely moral nature of the writer. His other chief work, the *Defense of Poesie*, published in 1595, after all that has since been written in the way of philosophical exposition on this and cognate subjects, will even now be found to repay the attention of the reader. Many of his shorter poems, more especially some of his sonnets, are also of rare merit. See Fulke Greville's Biography of S., Zouch's Memoirs of S. (1808) and H. R. Fox Bourne's *Memoirs of Sir Philip Sidney* (1862).

SIDNEY, or SYDNEY, ALGERNON, grand-nephew of the famous Sir Philip Sidney, was born in the year 1622. He received a careful education, and accompanied his father, the Earl of Leicester, to Denmark and France, whither the latter had been sent on embassies. In 1641 he served with some distinction against the rebels in Ireland, of which country his father was then Lord-lieutenant for the king. Subsequently, in 1643, along with his elder brother, the Viscount Lisle, he crossed to England, ostensibly to take service under the king, then at war with his parliament. The two brothers, however, on their arrival, joined the parliamentary forces. At the battle of Long Marston Moor, in which he was sharply wounded. Algernon's courage and capacity were conspicuous; and in evidence of the estimation in which he came to be held by his party, we find him, in 1646, Lieutenant-general of the Horse in Ireland, and governor of Dublin; and subsequently, in 1647, after receiving the thanks of the House of Commons for his services, appointed governor of Dover. The year before, he had been returned to parliament as member for Cardiff. In 1648 he was one of the judges at the king's trial, and though, for some reason not explained, he neither was present at the passing of sentence, nor signed the warrant of execution, his general approval of the proceedings is not doubted. He is reported to have afterwards spoken of the execution as 'the justest and bravest action that ever was done in England or anywhere else.' In principle a severe republican, he resented the usurpation of power by Cromwell, and during the Protectorate lived in retirement at the family seat of Penshurst, in Kent.

In 1659, on the meeting of the restored parliament, S. was again in his place. He was nominated one of the Council of State, and shortly after despatched to Denmark on a political mission. After the Restoration, he lived precariously on the Continent, flitting about from place to place, but in 1677, a pardon was procured him from Charles II., and he returned to his native country. Nevertheless, he was still obdurately republican in his opinions, and it is undoubted that he schemed for the overthrow of the monarchy, and the establishment of a republic in its stead; for this end he solicited the aid of the French monarch, and there is evidence of his having been supplied with money by Barillon, the French ambassador. Obscurely his designs were suspected, and in June 1683, when the Rye House Plot was announced, the opportunity was seized to get rid of a man felt to be dangerous. Along with his friend Lord Russell and others, he was arrested, and committed to the Tower. On the 21st November, he was tried for high treason before the brutal Jefferies, and on the merest mockery of evidence, found guilty, and condemned to die. On the 7th December he was beheaded on Tower Hill. He met his death with heroic firmness, amid general sympathy and indignation. He has ever since enjoyed a sort of canonized reputation as a patriot hero and martyr, and it cannot be held undeserved, narrow and impracticable as we must admit his views to have been. In the history and theory of government, S. was more deeply learned than any man of his time. His *Discourses concerning Government* were first published in 1698; in 1704, another edition was issued, a third appeared in 1751, and the fourth in 1772. S.'s life has been written by S. W. Meadley (Lond. 1813). See also Blencowe's *Sidney Papers* (Lond. 1813).

SIDNEY SUSSEX COLLEGE, Cambridge, was founded in 1598 by Lady Frances Sidney, Countess of Essex, or rather by her

executors, in obedience to the instructions of her will. They obtained of Queen Elizabeth a mortmain for the purpose, and purchased of Trinity College the site of the ancient convent of Franciscans, or Gray Friers. There are 10 fellowships.

SI'DON (Hebr. Zidon, perhaps 'fishing-place'), ancientry, a city of Phœnicia, situated on the east coast of the Mediterranean, in lat. 33° 34′ 5″ N., 45 miles south of Berytus. It was built on a rising mound, protected by the sea on the north and west; while the bed of a river formed a natural fosse to the south, and the high hills shielded it to the east; a double harbor gave shelter to its ships both in summer and winter. It soon rose, both by its exceptional position and the daring and enterprising character of its inhabitants, to the highest rank among the cities of Phœnicia (q. v.), so that the whole country is sometimes designated by the name of S., 'the Great,' 'the Metropolis.' The extensive commerce of S. is well known from ancient authorities. Its colonies extended over the coast of Asia Minor and the adjacent islands, the coast of Thrace and Eubœa, and even some parts of Sicily, Sardinia, Spain, the coast of Cornwall and the Baltic shores, the northern parts of Africa, and, in fact, nearly the whole of the ancient world. Their manufactures of glass and linen, purple dye and perfumes, were sources of unbounded wealth; and, whether they were the skilful workers, or merely the exporters and traders of those 'divine' works in gold and silver, ivory and bronze, which were the marvel of both Greeks and Hebrews, so much seems certain, that they managed to be considered unanimously the most skilful workmen of their time.

Although one of the cities assigned to the Israelites by Joshua, it never in reality belonged to them, but, on the contrary, was every now and then in arms against them, either singly, or in league with some of their deadliest enemies, and even subjugated them for a time. After being conquered itself by Tyre, the daughter-city, it attempted to throw off the yoke at the invasion of Phœnicia by Shalmanezer, to which king it surrendered. Under Assyrian, Chaldean, and Persian domination, it retained a kind of independence for its internal affairs, and under the Persians, actually reached its highest prosperity. But an unsuccessful revolt against that power, under Ochus, ended in its temporary ruin (351 B.C.). Speedily rebuilt and repeopled, it opened its gates to Alexander the Great (333 B.C.), and from that time forth it fell successively into the hands of Syrian, Greek, and Roman rulers. Through the middle ages, little is heard of it, except that it was taken by the Crusaders. During part of the 17th and 18th centuries, it again became an important place of commerce; but misrule and violence put an end to its rising prosperity, and the number of its inhabitants has sunk to about 5000. There is still some little export of silk, cotton, and nut-galls. It is now called Saida, occupies a place somewhat to the west of the ancient city, and belongs to the Turkish pashalic of Acre. See PHŒNICIA.

SIE'BENBÜRGEN (Seven Castles), the German name of the Austrian principality of Transylvania (q. v.).

SIE'BENGEBIRGE, a collection of conical heights in Rhenish Prussia, on the right bank of the Rhine, about 22 miles above Cologne. The highest of the peaks is the Löwenkopf or Löwenberg, 1560 feet high; but the most famous is the Drachenfels (q. v.).

SIEGE (Fr. a seat, a sitting down) is the sitting of an army before a hostile town or fortress with the intention of capturing it. With certain elements, the success of a siege is beyond doubt; the result being merely a question of time. These elements are: first, the force of the besiegers shall be sufficient to overcome the besieged in actual combat, man to man. If this be not the case, the besieged, by a sortie, might destroy the opposing works, and drive away the besiegers. The second element is, that the place must be thoroughly invested; so that no provisions, reinforcements, or other aliment of war can enter. The third element is, that the besiegers be undisturbed from without. For this it is essential that there shall not be a hostile army in the neighborhood; or, if there be, that the operations of the besiegers be protected by a covering army able to cope with the enemy's force in the field. The ancients executed gigantic works to produce these effects. To complete the investment, they built a high and strong wall around the whole fortress; and to render themselves secure from without, they built a similar wall facing outwards, beyond their own position. The first was circumvallation, the second contravallation. It was thus that Cæsar fortified himself while besieging Alexia, and maintained 60,000 men within his ring. In modern warfare, it is considered preferable to establish strong posts here and there round the place, and merely sentries and vedettes between.

Let us now assume that a fortress of great strength has to be reduced, and that the force of the enemy in the vicinity has been either subdued or held in check by a covering army. By rapid movements, the place is at once invested on all sides. This step constitutes merely a blockade; and if time be of little importance, is a sufficient operation, for hunger must sooner or later cause the fortress to surrender; but if more energetic measures are required, the actual siege must be prosecuted. Advantage is taken of any hidden ground to establish the park of artillery and the engineers' park; or if there be none, these parks have to be placed out of range. The besieging force is now encamped just beyond the reach of the guns of the fortress; and their object is to get over the intervening ground and into the works without being torn to pieces by the concentrated fire of the numerous pieces which the defenders can bring to bear on every part. With this view, the place is approached by a series of zigzag trenches so pointed that they cannot be enfiladed by any guns in the fortress. In order to accommodate the forces necessary to protect the workers, the trenches at certain intervals are cut laterally for a great length, partly encircling the place, and affording safe room for a large force with ample battering material. These are called *parallels*, and they are generally three in number. The distance of the first parallel will increase as small-arms become more deadly; but with the old smooth-bore muskets it was usual to break ground at 600 yards from the covered way of the fortress, while at Sebastopol, ground was broken at 2000 yards, and in the siege of Paris by the Germans, the lines were begun at least 4 miles from the city.

The locality of the parallel being decided on, a strong body of men is sent to the spot soon after nightfall. The attention of the garrison is distracted by false alarms in other directions. Half the men are armed cap-à-pie, and lie down before the proposed parallel; while the other half, bearing each pick and shovel, and two empty gabions, prepare for work. Each man deposits the gabions where the parapet of the trench should be. He then digs down behind them, filling the gabions with the earth dug out; and, after they are filled, throwing it over them, to widen and heighten the parapet. Before daylight, the working-party is expected to have formed sufficient cover to conceal themselves and the troops protecting them. During the day, they—being concealed from the garrison—widen and complete their parallel, making it of dimensions sufficient to allow of wagons and bodies of troops with guns passing along. During the same night, other parties will have been at work at zigzags of approach from the depôts out of range to the first parallel, which zigzags will be probably not less than 1000 yards in length. The profile of a completed trench is shown in fig. 1, the shaded portion representing a gabion. As a rule,

Fig. 1.—Profile of a Trench.

the defenders will not expend ammunition on the first parallel, for its extent (often several miles) will render the probability of doing material damage extremely small. For this reason also, the dimensions of the parapet and its solidity are of far less importance in the first parallel than in the more advanced works of attack.

The first parallel AAA, fig. 2, being completed, the engineers

Fig. 2.—Siege Works.

select points near its extremities, at which they erect breast-works, B, B, to cover the bodies of cavalry, who are kept at hand to resist sorties from the garrison. The length of the parallel is usually made sufficient to embrace all the works of two bastions at least. Sites are then chosen for batteries, C, C, which are built up of fascines, gabions, sandbags, and earth. They are placed at points in the parallel formed by the prolongation of the several faces of the bastions, ravelins, and other works of the fortress, which faces the batteries are severally intended to infilade by a ricochet fire. Other batteries will be formed for a vertical fire of mortars and shell-guns. By these means it is hoped that the traverses on the hostile ramparts will be destroyed, the guns dismounted, and the defenders dispersed, before the final approaches bring the assailants to the covered-way. The sappers will now commence their advance towards the points, or salient angles, of the two bastions to be attacked. If, however, the trench were cut straight towards the fortress, its guns could easily destroy the workmen, and enfilade the approach. To prevent this, it is cut in short zigzags—as at D—the direction always being to a point a

few yards beyond the outmost flanking works of the garrison. The side of each trench nearest the fortress is protected by gabions and sandbags, as in the case of the parallel.

At intervals, short spurs of trench, incipient parallels, are cut, as at E, to contain small-arms-men, to act as guards to the sappers. The second parallel is about 300 yards from the enemy's works, and has to be more strongly formed than the first. It often terminates in a redoubt, F, to hold some light artillery, and a strong force of infantry, who could assail any sortie in flank; or it may run into the first parallel, as G, giving easier access for troops than through the zigzags. The second parallel is riveted with sandbags, in which loopholes are left for musketry. After passing the second parallel, the angles of the zigzags become more acute, to prevent enfilading. At about 150 yards, certain demi-parallels, H, are cut, and armed with howitzer batteries, to clear the covered-way, while riflemen also act from it. The third parallel is at the foot of the glacis. Thence the place, after being sufficiently battered, is taken by a storming-party, who make their way over the glacis, or the covered-way is topped by the double sap, as in fig. 3; which is a safer plan for the army generally, though much more deadly to the sappers. When the crest of the covered-way has thus been reached, batteries of heavy artillery will be there established, for the purpose of breaching the walls of the ravelin and bastion; while at the same time miners will first seek to destroy the defenders' counter-mines (which would otherwise be likely to send these batteries into the air), and then will excavate a tunnel to the ditch, at the foot of the counterscarp.

Fig. 3.—Double Sap.

If the breach becomes practicable, a storming-party will emerge from this tunnel or gallery, and seek to carry the opposite work by hard fighting. If inner works still subsist, which would tear assailants to pieces, the double sap may be continued across the ditch, if a dry ditch, right up the breach, that counter-batteries may be formed. If the ditch be wet, means must be adopted for a causeway or a bridge. By these means, however obstinate may be the defence, if the besieging force be sufficiently strong, and aid do not arrive from without, the ultimate success of the attack becomes certain. Vauban raised attack to a superiority above defence, first, by the introduction of ricochet fire, which sweeps a whole line; and secondly, by originating parallels. Before his time, the whole attack was conducted by zigzag approaches; in which the troops actually in front could be but few, and were therefore unable to withstand strong sorties of the garrison, who, in consequence, frequently broke out and destroyed the works of the besiegers, rendering a siége an operation of a most uncertain character.

SIEGE-ARTILLERY is heavy ordnance used for battering purposes, and of too weighty a character to take the field. A siege-train of guns and their ponderous ammunition is usually maintained in the rear of an army, ready to be brought up for use when required.

SIE'GEN, a manufacturing town of Prussia, in Westphalia, stands on the Sieg, 38 miles south-south-west of Arnsberg. In 1880, it had 15,024 inhabitants, who are engaged in manufacturing leather, cotton, and woollen goods. S. is also said to produce the best iron in the west of Germany. In the vicinity are numerous iron mines and smelting furnaces. Its iron and steel wares are noted; especially its files.

SIEGFRIED. See NIBELUNGENLIED.

SIEMENS' FURNACE. See GLASS, IV. 777.

SIE'NA, a city of Central Italy, 60 miles south of Florence. Pop. (1881) of town, 7903; of commune, 25,204. It is situated on three little hills, separated from each other by valleys, and higher than other hills surrounding them. Its climate is on this account very salubrious, notwithstanding the deficiency of water caused by its elevated position; to remedy which, subterranean aqueducts had been excavated five miles in length, some of them dating as far back as the Roman dominion. Its environs are not beautiful, consisting of naked clay-hills, capped with sandstone, but the city is surrounded by trees and avenues, which have a fine effect. The handsome square, Piazza del Campo, is one of the finest in Italy. Eleven streets lead out of it, and it is surrounded by handsome buildings. In this square there is also the famous tower called the *Mangia*, of prodigious height; there are also other towers here and there, seen from a great distance—remnants of the habitations of the feudal lords. The streets are narrow, some paved with tesselated bricks, and others flagged. There are many ancient Gothic palaces, not remarkably handsome.

In the Piazza del Campo stands the Palazzo Pubblico, built in the 13th c., in which there are magnificent rooms, and paintings by eminent artists. S. has a fine cathedral, erected, it is said, on the foundations of the Temple of Minerva, begun in 1059; the façade built in the 13th century. It is faced with black and white marble, and is covered with ornaments and sculptures. The pavement is of marble tesselated, representing many biblical subjects. In the different chapels, and in the baptistery, there are frescoes, paintings, and statues, by a number of distinguished masters. The other churches are also rich in works of art. Of the many oratorios, the most noteworthy is that of St. Catharine (q. v.), occupying the house of the saint. S. is an archiepiscopal see. The Sienese are singularly industrious, and have numerous manufactories of cloth and woollen, silk and linen stuffs, of felt and straw hats, of wax and beet-sugar. There are marble quarries in the neighborhood. There is a university, founded in 1330, famous especially as a school of medicine, which has upwards of 100 students. The Italian spoken at S. is reckoned among the purest.

S. was founded as a Roman colony in the time of Julius Cæsar, under the name of Sena, or Sena Julia. There are no remains of antiquity; and it does not appear to have been a place of any consequence until the middle ages, when it became one of the powerful city republics of Italy. It embraced the Ghibelline cause, and in conjunction with the forces of Pisa, defeated the Tuscan Guelfs, in the memorable battle of Monte Aperto (1260). At the height of its greatness, it is said to have contained 200,000 inhabitants. S. produced a 'school' of artists, of whom the most distinguished names are Guido da Siena, Simone Memmi, Sodoma, Beccafumi, and Baldassare Peruzzi.

SIENNA EARTH. See BURNT SIENNA.

SIE'RRA, a name applied in Spain, and in countries in which the Spanish language has prevailed, to a ridge of mountains. The word means *saw*, and is descriptive of the notched or saw-like skyline of certain mountain ranges.

SIE'RRA LEO'NÉ (Mountain of the Lion), a British colonial settlement on the Sierra Leone coast, Western Africa. The settlement consists chiefly of a peninsula, just to the south of the Sierra Leone River, on which the capital, Freetown, stands; a strip of territory along the coast to Sherboro River, 50 miles to the south; and the Isles de Los, and Sherboro (added in 1862). The area is stated at 468 sq. miles (other accounts say 1000), and the pop. in 1881 was 60,546 (of whom only 250 are whites). In 1883 an additional strip of territory extending from Sherboro to near the borders of Liberia was annexed by Britain. Along the coast stretches a belt of rich low-lying land, and elsewhere in the colony there are fertile tracts; but the interior is a mass of rugged mountains, with a generally barren soil. The climate is humid and unhealthy—the wet season, lasting from May to November, being specially pestilential. Tropical fruits and plants grow luxuriantly in the more favorable regions, and coffee, sugar, indigo, and cotton have been introduced by the British. In 1872, the exports amounted to £358,636, the chief articles being gold, cotton goods, ground-nuts, palm-oil, hides, palm-nuts, manufactured tobacco, and timber. In the same year, the imports amounted to £411,936, and the chief articles were cotton goods (nearly one-half of the whole value), gunpowder, ready-made apparel, hardware, haberdashery, and rum. In 1877, S. L. and Gambia exported to Great Britain goods valued at £176,111, and imported thence to the value of £604,391; in 1880, the corresponding exports were valued at £157,964, and the imports at only £388,650. The colony is ruled by a crown-appointed governor, assisted by a council. In 1866, S. L., the Gambia, the Gold Coast, and Lagos were placed under one general government, to be called the 'Government of the West African Settlements.'

The settlement of S. L. was established in 1787, when 470 destitute negroes were removed to it from London by a body of philanthropists; and 1196 negroes were sent to it from Nova Scotia—the climate of which had proved too severe for them—in 1790. The population was also increased by other bands of people of color; and after the abolition of the slave trade in 1807, the slaves captured by British cruisers have been put ashore, and settled here. In 1820, the settlement contained only 12,000 inhabitants, or less than a fifth of its present population.

SIERRA MA'DRÉ, a name given to central portions of the great chain of Cordilleras or Rocky Mountains, in Mexico, from lat. 19° to 25° N., and in New Mexico, to the great western range, from lat. 34° to 38° N. These ranges, but partially explored, contain some of the richest silver mines in the world.

SIERRA MORE'NA, a mountain-range in Spain, on the southern border of New Castile, and between the modern provinces of Ciudad Real and Jaen. It separates the upper portions of the basins of the Guadiana on the north, and of the Guadalquivir on the south, and rises in its highest point to 5500 feet above the sea. It is frequently mentioned in *Don Quixote*, and is the scene of many of the incidents therein described.

SIERRA NEVA'DA (*Snowy Range*), a mountain-range of Spain in Andalusia, extending east from Padul, 12 miles south of Granada, to the frontiers of the modern province of Almeria, is 60

miles in length, from 20 to 30 miles in breadth, and covers an area of upwards of 1000 square miles. It is continued on the north-east by the Sierra de la Filabras, and forms a portion of the watershed between the streams that flow into the Mediterranean and those that flow into the Atlantic. The peak of Mulhacen reaches a height of 11,678 feet, and is the highest summit not only of the Spanish Peninsula, but of the whole of Europe west of the Alps. The peak of Veleta is 11,387 feet high. The range receives its name from the perpetual snow which covers the highest summits. The views from the summits, from which, on the south, may be seen the faint outline of the African coast, on the north, the jagged sierras of the Castiles, can hardly be surpassed in beauty and magnificence by any in Europe.

SIERRA NEVADA, a range of mountains in California, forming a portion of its eastern boundary, is the source of a multitude of rivers, which swell the Sacramento and San Joaquin. The range extends from north-west to south-east 450 miles, and is united to the coast-range, which runs parallel with the Pacific, by Mount San Bernardino. Among the higher peaks of the S. N. are Saddle Peak, 7200 feet high; Table Mountain, 8000 feet; and the Buttes, 9000 feet. Here are immense deposits of gold quartz, with steam and water power crushing-mills; deep tunnels and mines, increasing with their depth their yearly product.

SIEYÈS, EMMANUEL JOSEPH, COMTE, who, as the Abbé S., prominently figures in the history of the French Revolution, was born at Fréjus, May 3, 1748. He was educated at the university of Paris with a view to his entering the church; and on the completion of his studies, he obtained the appointment at Treguier, in Bretagne (1775), whence, in 1780, he was transferred to the cathedral of Chartres, of the diocese of which he became chancellor and vicar-general. He had early imbibed the extreme liberal opinions on all matters social and political which were preparing the French Revolution; and when, in 1789, the States-general were summoned, he issued his famous pamphlet, entitled *Qu'est-ce que le Tiers Etat?* This work, which claimed for the people political recognition, naturally enough obtained an immense popularity for its author, and procured his election as one of the deputies for Paris. Mainly through his urgency and influence it was that, on June 16, 1789, the representatives of the people took the decisive step of constituting themselves into an independent body, and became the National Assembly. Of this body he continued for some time to be one of the most prominent and leading figures. In 1791, he was elected to the Legislative Assembly, then convened, as member for the department of Paris. By this time, however, he had sunk somewhat from his first pre-eminence; bolder and fiercier spirits had passed him in the race for power and popularity, and where he had once led, he now reluctantly followed. In the Convention of 1792, to which he was elected as deputy of the department of La Sarthe, he prudently refrained from any active participation in the debates, and on the occasion of the king's trial, he recorded a silent vote.

Whilst Robespierre and his party were in power, he consulted his safety by retiring from Paris. When afterwards asked what he had done during the Reign of Terror, he quietly replied: *J'ai vécu* ('I have lived'). On the fall of Robespierre, he returned to his post in the Convention, and resumed his active interest in affairs, becoming a member of the new Committee of Public Safety. He was engaged chiefly in the department of foreign policy, and he went as ambassador to Holland and Berlin successively to negotiate treaties of alliance. He became a member of the Directory in 1799, and among other reactionary measures, he succeeded in closing the celebrated Jacobin Club. Perceiving that a stable government was on no other terms possible, he became anxious to secure the co-operation of some powerful military leader, the more particularly as he was ambitious above all things of giving France a 'constitution' (of which he had drawn up one or several); and on the return of Bonaparte from Egypt, he entered into a league with him, the result of which was the revolution of the 18th Brumaire (November 9, 1799), and the institution of the Consulate, S., Napoleon, and Roger Ducos being the three first consuls. Speedily, however, S. discovered in his new ally his master.

As to the distribution of power in the new constitution to be formed, he and Napoleon differed irreconcilably; the man of bayonets was the stronger; his political nostrums never got beyond the paper on which they were written; and finally, in disgust at the subordinate position into which he found himself about to sink, S. threw up his place in the government. As a reward of his services, he received on his retirement a sum of 600,000 francs and the estate of Crosne; afterwards exchanged for the equivalent of a splendid hotel in Paris and the lands of Fainanderie, in the park of Versailles. Also the title of Count was conferred upon him. Subsequently, the presidency of the Senate was offered him, but he declined it, and never afterwards concerned himself in public affairs. Banished at the Restoration, he did not return to France till after the revolution of 1830; and in Paris, on June 20, 1836, he died. During the revolution, S. drew up a good many papers of one kind and another; but he is chiefly remembered for his plan of a new constitution, which, however, is very little known. Mignet's *Histoire de la Révolution* contains a description of it; and under the title of *Théorie Constitutionelle* of S., and *Constitution de l'An VIII.*, M. Boulay (de la Meurthe) published (Par. 1836) from S.'s own *Mémoires inédits* a more detailed account.

SIGHING, THE ACT OF, is nothing more than a very long-drawn inspiration, in which a larger quantity of air than usual is made to enter the lungs. This is continually taking place to a moderate degree, and Dr. Carpenter remarks that it particularly occurs when the attention is released, after having been fixed upon an object which has strongly excited it, and which has prevented our feeling the insufficiency of the ordinary movements of respiration. Hence this action is often a simple result of deficient aëration; while in other cases, as is universally known, it is excited by a depressed state of the feelings.

SIGHT, DEFECTS OF. Under this head we shall consider such affections of the eyesight as are due to some known or unknown peculiarity of the optical apparatus (including the optic nerve) not dependent on disease—viz., *short-sight, long-sight, double vision, color-blindness,* and *night-blindness.*

Short-sight, near-sight, or *myopia* (derived from the Greek words *myo,* I close, *ops,* the eye), is often popularly confounded with dim or weak sight; but in reality, short-sight applies exclusively to the *range* and not to the *power* of sight, and a short-sighted person may possess the acutest power of vision for near objects. In this affection, the rays which ought to come to a focus upon the retina converge to a point more or less in front of it. The cause of this defect probably differs in different persons. It may arise from over-convexity of the cornea or the lens, from undue density or abundance of the humors of the eye, from elongation of the globe in its antero-posterior diameter, or from an imperfect power of the eye to adjust itself to objects at various distances. The distance at which objects are perceived most distinctly by the perfectly normal eye ranges from 16 to 20 inches; an eye which cannot perceive objects distinctly beyond 10 inches may fairly be regarded as short-sighted; and in extreme cases, the point of distinct vision may be three, two, or even only one inch from the eye. Short-sight is frequently hereditary in families. As a general rule, the inhabitants of towns are much more liable to it than persons living in the country, and students and literary men are the most liable of all. While in the Foot-guards, consisting of nearly 10,000 men, 'not half-a-dozen men have been discharged, nor have a dozen recruits been rejected on account of this imperfection, in a space of 20 years, in one college at Oxford no less than 32 short-sighted men (or *myopes*, as they are termed by some oculists) were met with out of 127' (Donders, *On the Accommodation and Refraction of the Eye*, London, 1864, p. 342). The frequency of this affection in the cultivated ranks points directly to its principal cause—tension of the eyes for near objects.

The myopia depending, as Donders believes, upon prolongation of the visual axis, this eminent physiologist inquires: 'How is this prolongation to be explained? Three factors may here come under observation: 1. Pressure of the muscles on the eyeball in strong convergence of the visual axes; 2. Increased pressure of the fluids resulting from accumulation of blood in the eyes in the stooping position; 3. Congestive processes in the base of the eye, which, leading to softening, give rise to extension of the membranes. That in increased pressure, the extension occurs principally at the posterior pole, is explained by the want of support from the muscles of the eye at that part. Now, in connection with the causes mentioned, the injurious effect of fine work is, by imperfect illumination, still more increased; for thus it is rendered necessary that the work be brought closer to the eyes, and that the stooping position of the head, particularly in reading and writing, is also increased. Hence it is that in schools where, by bad light, the pupils read bad print in the evening, or write with pale ink, the foundation of myopia is mainly laid. On the contrary, in watchmakers, although they sit the whole day with a magnifying glass in one eye, we observe no development of myopia, undoubtedly because they fix their work only with one eye, and therefore converge but little, and because they usually avoid a very stooping position.'—*Op. cit.*, pp. 343, 344.

So far from short-sightedness improving in advanced life, as is popularly believed, it is too frequently a progressive affection; and every progressive myopia is threatening with respect to the future. 'If,' says Donders, 'it continues progressive, the eye will soon, with troublesome symptoms, become less available, and not unfrequently, at the age of 50 or 60, if not much earlier, the power of vision is irrevocably lost, whether through separation of the retina from the choroid, from effusion of blood, or from atrophy and degeneration of the yellow spot.'

In the treatment of myopia the principal objects are: 1. To prevent its further development and the occurrence of secondary

disturbances; and 2. By means of suitable glasses, to render the use of the myopic eye easier and safer.

1. To effect, if possible, the first object, the patient must look much at a distance, but as we cannot absolutely forbid his looking at near objects, spectacles must be provided which render vision distinct at from 16 to 18 inches. Moreover, it is desirable that at intervals of a half hour work should be discontinued for a couple of minutes, and no working in a stooping position should be permitted. The patient should read with the book in the hand, and in writing should use a high and sloping desk.

2. The optical remedy for short-sight obviously consists in concave glasses of a focus suited to the individual case. At first sight, it might be supposed that glasses with a concavity exactly sufficient to neutralize the defect in the eye, would always suffice; and when the glasses are used exclusively for distant vision (for example, in the double eye-glass, which is only at intervals held before the eye), or when the affection is slight, and the eye is otherwise healthy, perfect neutralization is admissible; but so many circumstances forbid the complete neutralization of the myopia, that an oculist of reputation should always, if possible, be consulted as to the choice of spectacles. Glasses, if injudiciously selected, usually aggravate the evil they are intended to remedy; and in connection with this subject, we must warn our readers against the prevalent habit of employing a single eye-glass; it is most prejudicial to the eye which is left unemployed, and often leads to its permanent injury.

Long-sight and *presbyopia* (derived from the Greek words *presbys* an aged person, and *ops*, the eye), are usually considered by English writers as synonymous terms. Donders, who is now universally accepted as the highest authority on this department of eye-affections, maintains that 'the term presbyopia is to be restricted to the condition in which, as the result of the increase of years, the range of accommodation is diminished, and the vision of near objects is interfered with.' As from youth up to extreme old age, the vision of near objects becomes progressively more and more difficult, it is impossible to fix any limit as the commencement of presbyopia.

In practice, however, a word is required which indicates the condition in which the eye, at an advanced period of life, and sometimes sooner, requires convex spectacles for distinct near vision, as, for example, for reading, and this word is *presbyopia*. In this state, the nearest point of distinct binocular vision is found to lie about 8 inches (or double the ordinary distance) from the eye, and at this point Donders arbitrarily places the commencement of presbyopia. This condition, which is as natural as a concomitant of advanced life as gray hairs or wrinkles, is occasionally met with in young persons. In these cases it generally arises from intestinal irritation, and may be a precursor of amaurosis; hence such cases should be carefully watched. In ordinary presbyopia, the defect is at once remedied by the use of glasses of low convex power, as of thirty or twenty-four inch focus, which should, however, only be worn during reading, and writing, and not constantly. Although the improper use of convex glasses is not by any means so dangerous as the inconsiderate use of concave glasses, the advice of a good oculist regarding the choice of spectacles is well worth his fee.

Double vision, or *diplopia*, is of two kinds. It may arise from a want of harmony in the movements of the two eyes, the vision of each eye singly being perfect; or there may be double vision with one eye only. The first form may occur (1) in cases of squinting, or (2) in cases of paralysis of one or more of the muscles of the orbit. In cases of Squinting (q. v.), the vision of the most distorted eye is almost always imperfect; and it is well known that impressions on the two retinæ are similar in kind but dissimilar in form. The mind takes cognizance only of the former; so that a person with a bad squint sees objects with the sound eye only. But if the sight of both eyes is nearly equal, as often is the case, when the squint is not very well marked, double vision results whenever both eyes are employed together, in consequence of images of nearly equal intensity falling on non-corresponding parts of the two retinæ. This variety of double vision, although annoying, is perfectly harmless. When double vision arises from muscular paralysis, disease of the brain of a serious nature is to be apprehended, although the affection sometimes appears to arise from exposure to cold. The second form of double vision—viz., double vision with a single eye, is a much more rare affection than the preceding one, and depends upon some irregular refraction of the cornea or lens.

Color-blindness is noticed under its own name.

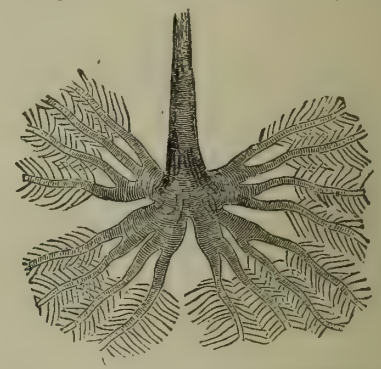
Night-blindness, or *hemeralopia* (from the Greek, signifying 'day-sight'), is a peculiar form of intermittent blindness, the subjects of which see perfectly with an ordinary light, but become entirely and almost instantaneously blind as soon as twilight commences. It is seldom met with in this country except among sailors just returned from tropical regions. It is frequent among the natives of some parts of India, who attribute it, as our own sailors do, to sleeping exposed to the moonbeams. The most probable cause of the affection is, however, exhaustion of the power of the retina from over-excitement from excessive light, so that this organ is rendered incapable of appreciating the weaker stimulating action of twilight or moonlight. All that suggests itself in the way of treatment is to protect the eyes from strong light during the day, and to prescribe quinine and a nourishing mixed diet.

Snow-blindness must be regarded as an allied affection to the preceding. See VISION.

SIGHT OF A GUN. See GUNNERY.

SIGILLA'RIA, a genus of fossil plants which are of importance because of their singular structure, and their remarkable abundance in the coal measures. They seem to have contributed more than any other genus of plants to the formation of coal. The roots of S. are found preserved in the shale which forms the floor of all coal-seams. These roots were originally supposed to be distinct plants, and have received the generic name of Stigmaria. The most feasible notion, and that generally accepted regarding them, was that they were fleshy water-plants, with numerous linear leaves, articulated to the stem by papillæ, which were buried in deep cylindrical hollows in the stem. Brongniart first suspected that they were roots, and Binney placed the question beyond doubt by discovering a specimen in which the trunk of a S. rose from the crown of a Stigmaria. Several observers have subsequently seen these fossils also in actual contact.

It is believed that the mud (now converted into shale) in which they grew was very soft, and easily permitted the passage of the large roots, while they gave off all round innumerable large hollow rootlets. The stems of S. are abundant in the coalbeds. They are marked by parallel longitudinal flutings, and regular scars formed by the base of the leaf-stalks, which had fallen off. They are known to have attained a height of 70 feet, and a diameter of 5 feet. The stem rose without branching till near the summit, when it branched several times dichotomously. The proportion of woody matter to cellular tissue in the stem was very small. The woody fibre is characterized by the abundance of



Trunk of Sigillaria rising from the Stigmaria Roots (*E. W. Binney*).

scalariform vessels, similar to those which occur in *Lepidodendron*, and in the recent vascular Cryptogamia. The stem is seldom found preserved so as to exhibit any structure, or even its cylindrical form; it generally occurs as a double layer of coal, showing on the outer surfaces the scars produced by the bases of the leaf-stalks. The form and arrangement of these scars have been used to distinguish the species, and indeed, no other materials exist, for hitherto no foliage of any kind has been certainly found connected with the trunks. The restoration of the genus has been consequently quite imaginary.

Some, with Brongniart, have supposed that the trunk terminated in a crown of simple leaves, like that of many palms, and that it was a gymnosperm near to the Cycads. Others, with King, consider that the fronds of *Pecopteris nervosa*, which are very abundant in the coal measures, are its foliage, and they would restore it so as to have the appearance of a modern tree-fern. And others, with Binney, consider that its affinities are nearer to *Lepidodendron*, and that some of the numerous fragments which have been referred to this genus may really be the branches of Sigillaria. They would restore it as if it were a huge *Lycopodium*, and refer to it some of those fruits which, under the names of *Lepidostrobus* and *Flemingites* have been described by Brown, Hooker, and Carruthers.

SIGISMUND, emperor of Germany (1411—1437), was the son of the Emperor Karl IV. He was well educated, and having married Maria of Anjou, on her accession to the throne of Hungary he became chief administrator of that kingdom. The death of his wife in 1392 made him king of Hungary; and at the head of a numerous army of more than 100,000 men, composed of Hungarians, French, Germans, and Poles, he attempted to relieve the Byzantine empire from the fierce Turks, but was terribly de-

feated at Nicopolis (28th September, 1396). On his return to Hungary, he found on the throne a new monarch, Ladislas of Naples, who imprisoned him (1401); but through the good offices of his elder brother, Wenceslas, he was freed, and obtained the throne (1402), rewarding his elder brother by snatching from him his kingdom of Bohemia, which he retained for some time.

In 1411, he was proclaimed emperor, on the death of Rupert. He was present at the Council of Constance, which he had prevailed upon Pope John XXIII. to hold for the purpose of putting an end to the Hussite and other schisms. He contented himself with protesting against the violation of the imperial safe-conduct which was given to Huss, and ultimately consented to his judicial murder, for the purpose, as his apologists say, of conciliating the council, and so settling the disputes concerning the papacy. His succession to the throne of Bohemia, after his brother's death, was opposed by the Hussites, who were now in insurrection; and after a fruitless attempt to conquer them, he confined himself to the defence of Hungary against the Turks, whom he defeated in a great battle near Nissa (1419). For ten years afterwards, he left Germany very much to the guidance of its self-willed petty rulers, who speedily brought the country into such a deplorable state that they were glad to beseech S. to return to the helm of affairs —which he did, but with little good effect. He obtained, by concessions to the Calixtines (q. v.), the crown of Bohemia in 1436; but once on the throne, he gradually withdrew these concessions, which provoked such discontent, that his death (1437) alone averted a civil war. S. possessed a large intelligence, and remarkable political talents, but these were much neutralized by his impetuosity, indecision, selfishness, and extraordinary avarice; and his well-meaning endeavors after peace and improvement ended in nothing. Carlyle distinguishes S. by the epithet *Supra Grammaticam*, in allusion to his answer to a cardinal at the council of Constance, who ventured to correct his majesty's grammar—'I am the Roman king, and above grammar.'

SIGISMUND, worthily surnamed the GREAT, king of Poland, was the youngest son of Casimir IV., and was born at Koziénicé, 1467. He was chosen Grand Duke of Lithuania, 1506, and succeeded to the kingdom of Poland on 8th December of the same year. The affairs of Poland and Lithuania were at that time in a sad condition; the southern portions of the country reduced almost to a desert by the ravages of the Tartars, while the east was continually in dread of the Russians, who had become an independent, united, and powerful monarchy. The Russians invaded Lithuania, and conquered some provinces, but S. gained a brilliant victory over them at Orsza on the Dnieper (14th July 1508). Bogdan, Prince of Moldavia and Walachia, now invaded the southern provinces, as that semi-barbarous race were accustomed to do without let or hindrance; but he was so decisively routed on the banks of the Dniester, that he gladly agreed to acknowledge himself a vassal of Poland. Disregarding the suggestions of the pope to head a crusade against the Turks, S. next read the Tartars, through his general, Ostrogski, a very forcible lesson, in 1512, against aggressive practices, which cost them 27,000 men, and assured the tranquility of his frontier for a long period. His alliance in 1513 with Stephen Zapoli, voyvode of Transylvania, whose daughter, Barbara, he also married, alarmed the Emperor Maximilian, who incited the Russians to resume their aggressions, which that ill-advised nation cheerfully agreed to do; paying dearly for their rashness, for their army of 80,000, which had invaded Lithuania, was met and cut to pieces (8th September 1514) by Ostrogski, with 32,000 men, at Orsza, leaving its standards, cannons, and other arms, 2 generals, 37 princes, 6000 prisoners, and 30,000 dead in the possession of the enemy. Subsequent invasions of Moscovites and Tartars were repelled as before, and a rebellion of the Walachs was punished by numerous defeats, chief of which was that of Obertyn (1531).

The insolence of the Teutonic Order, who had invaded Polish Prussia, was effectually chastised by S., who defeated their Grand Master Albert, his own nephew, in two great battles, in the latter of which the knights were assisted by the Danes (1520). In 1525, he agreed to confer on Albert the title of Duke of Prussia (now known as East Prussia) on condition of fealty and homage. The dukes of Prussia continued as vassals of the Polish crown till 1657. In 1526, S. alone of the monarchs of Christendom lent aid to Hungary against the formidable array of Solyman the Magnificent, and a numerous force of Polish cavaliers fought bravely on the fatal field of Mohacz (1526). The only other important event of S.'s reign was the introduction and extension of Lutheranism in Poland, a change which S. did nothing to prevent, only taking precautions, and sometimes severe ones, against its affecting the civil and political condition of the country. It is told of him that, when John Eck exhorted him to take severe measures with the Lutherans, whom he compared to goats among sheep ('the faithful Catholics'), S. replied that he was desirous of being 'king of goats as well as king of sheep.' After a long and glorious reign, S. died at Cracow, 1st April 1548, leaving the character of a just, wise, and magnanimous prince, who had restored to his country its ancient prosperity, and had raised it from the very feet of its enemies to a worthy superiority over them.

SIGNALS are the means of transmitting intelligence to a greater or less distance by the agency of sight or hearing. Incomparably the most powerful medium yet known for this purpose is the electric current. See TELEGRAPH. Sound signals have obviously but a short circuit. The electric current requires fixed apparatus establishing an actual communication between the two points; and is therefore inapplicable to the ordinary cases of ships interchanging signals with each other or with the shore; and, except under unusual circumstances, it would not apply to armies manœuvring in the field. For these purposes, so far as present knowledge extends, signals by sight or sound must always be the resort. For railway signals, see RAILWAYS.

The ancients seem to have elaborated a fair system of night-signals by torches for military purposes; but in naval affairs the ships sailed so close together, that orders could be communicated by word of mouth, while the turning of a shield from right to left sufficed as sailing directions to the several lines. In modern times, signalling between ships has become indispensable; but there is probably no department of practical science in which progress has been slower, and every so-called system of signals has been distinctly without any system whatever. In the time of James II., a signal could only be expressed by flags, in confusing number, hung in different parts of the vessel. By the commencement of the present century, thanks to Sir Home Popham and other inventors, the system had been adopted of hanging a number of flags under one another, each symbol or combination having an arbitrary conventional meaning attached to it.

Alterations in the specific flags have been made from time to time, but essentially this is the system now in use. The flags are either square, triangular of the same length, or pendants which are pointed and longer. These are of black, white, red, blue, and yellow (in the Austrian service alone green is added) in mass or in combination. Specimens of the flags in use in the present naval code are shown in fig. 1. The signalmen find, however, that at a

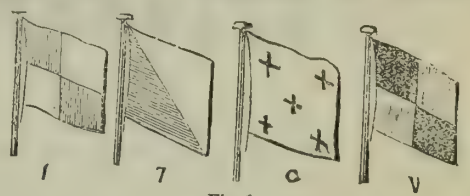


Fig. 1.

distance blue, red, and black are not readily distinguishable, nor yellow from white. It has consequently been the recent tendency, and apparently most justly, to reduce all the signs to black and white, singly or in combination, trusting to shape for different signals.

There are, however, disadvantages attending flags. In a still day, they are difficult to read; or the wind may so blow that they are only seen end on. At sea, the motion of a ship will generally neutralize these drawbacks; but the case is otherwise on shore, and it may consequently occur that the ship can communicate to the land, but cannot get a reply. To obviate this, signals representing solid figures are sometimes employed. To fulfil their conditions, they must appear the same in whatever lateral direction seen. But this limits the shapes to cylinders, cones, and the sphere, or combinations of those figures; and as the total number of distinguishable signs is reduced, signalling becomes reduced from the word-signal to the telegraph. This distinction should be clearly understood, as much is involved in it.

A word-signal, as in the present system, is where the whole word or message is sent up at once, and flies simultaneously; a telegraph signal is one in which the letters composing the word or numbers representing the signal are shown separately, and each is removed before another is shown. At sea, the word-system is best, for it involves no act of memory; and memory, even from signal to signal, is found difficult by signalmen in the turmoil of perhaps storm or fighting. On the other hand, the telegraph system involves far simpler apparatus, and the changes can be effected more rapidly. As regards the actual time required for a message, the word-system has the advantage in a message short enough for the whole to be shown at one time; but otherwise the difference is not material. If all advantages be balanced, it is probable that the telegraph system will eventually supersede the other entirely. Whether the word or the telegraph system be practised, another question is, whether to spell each word, or to use numerals and a code. Under the latter principle, about 14,000 of the words and sentences most commonly sent are arranged for easy reference in the signal-book. With the addition of 1 or 2 repeating symbols, the 9 numerals and 0 give combinations 4 together to this number. A combination of figures is arbitrarily

assigned to each expression; and the expression is communicated by representing those figures in their proper order. With the book of reference at hand, and intelligent signalmen, there can be no doubt of the superior rapidity of the 'code.' A code has also this further advantage, that the signals representing things and not words, it can be made international, the same symbols representing the same idea in every language. It is then only necessary for universal signalling that each nation should concur in the meaning to be attached to the several signs.

Many gentlemen of ability have devoted their attention of late years to the simplification of signals; among whom conspicuous positions must be assigned to Colonel Grant, Colonel Bolton, Mr. Redl, and Captain Colomb, R.M. Their principal object has been so to simplify the telegraph system that signals may be made with any apparatus, or without apparatus at all. To accomplish this, they have to a great extent, abjured color, and resorted to form and motion. Among the form telegraphs there is the principle of the old Semaphore (q. v.), in which each letter or number is shown by the position of two arms, as in fig. 2. The arms are heavy, and involve mechanism; besides which they are not always clear on a ship in motion beyond a short distance.

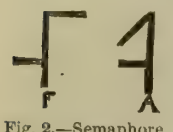

Fig. 2.—Semaphore System.

Very superior in visibility and simplicity is Redl's System of Cones. This consists of 4 cones fixed to a mast. The cones are collapsable, and are formed in a similar manner to umbrellas. Their usual condition is shut, and they can only be held open while a rope attached to each is pulled. With cones of 3 feet base, signalling is rapid and clear up to 5 miles, and the mast can be inserted at any place. The system is very simple: each cone represents a number, 1, 2, 3, or 4; then 1 and 4 shown represent 5; 2 and 4, 6; and so on, as in fig. 3.

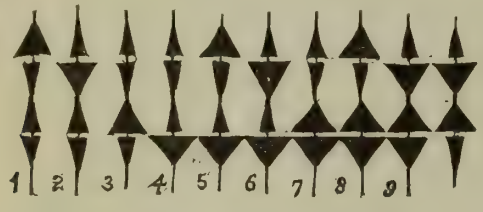

Fig. 3 —Cone System.

This very elegant system can be applied in military or naval operations. But its chief beauty is, that a person understanding it can make the same signals without the cones; for example: if a black flag represent an open cone, and a white flag a shut cone, a ship with 4 black and 3 white flags can make every signal. Again, the arm raised horizontally may represent the open cone; against the body, the shut cone; then two men standing on a cliff are as good as any signal-post, see fig. 4. Or if one person only

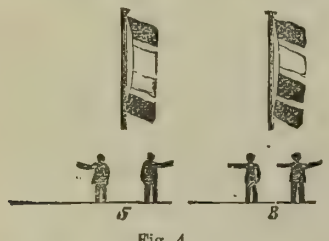

Fig. 4.

be present, he may represent an open cone by raising his arm with a handkerchief extended, and a shut cone by his arm without the handkerchief. He has only then to raise his arm four times in quick succession, with or without the handkerchief, to make the required signal. We have thus arrived at a universal system of the utmost simplicity, which in war and especially during invasion, might be of inestimable benefit to the nation. The code of signals cannot be too generally diffused by the government.

It only remains to apply the same system to night-signals. The old naval principle has been to hang dingy lanterns in various shapes—triangles, squares, crosses, &c. Besides requiring large bases to be at all visible, this has been found from the motion of a ship to be nearly useless. Redl's system has been applied by hanging four lanterns in a vertical line to represent the cones, and obscuring those which corresponded to shut cones. An improvement was found in introducing a red or green light in the middle, to show the relative positions of the four. The best night-signals are, however, flashing lights, as introduced by Colonel Bolton, and more elaborately by Captain Colomb, and adopted in the navy. This consists of a bright light, covered by a shade, which shade, by mechanism, can be lifted for any given time, exposing the light meanwhile. A flash of about half a second's duration is negative: a line of 1½ seconds, positive. Four exhibitions of the light then represent a symbol as in Redl's cones. If the same nomenclature be adopted, we should signal as in fig. 5. It will

Fig. 5.

be seen at once that this system produces results similar to Morse's Electric Telegraph. If the distance be within a mile or so, and the weather still, a bugle will answer equally well, long and short notes representing the positive and negative cones.

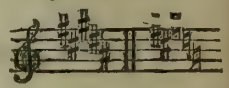
Heliography is now largely used for military signalling where there is plenty of sunshine. The heliograph is simply a mirror on a stand, capable of being swung horizontally as well as vertically, with a small hole in the mirror to look through, so as to direct it accurately. Two trained sappers with heliographs can easily flash signals to one another at a distance of 50 miles, and so communicate even without the help of a telescope.

SI'GNATURE, in Music. In writing music in any key with sharps or flats, the sharps and flats belonging to the key, instead of being prefixed to each note as required, are placed together immediately after the clef on the degrees of the staff to which they belong; and this collection of sharps or flats is called the signature. The signatures of the several keys generally in use are as follows:

The minor keys take the same signature with the major keys a third above them.

When a new key is introduced in the middle of a piece of music, the signature of the former key must be contradicted, and that of the new one appended. Thus a transition from the key of D major to that of D minor, is indicated thus:

from B major to B minor:



the sharps which are to continue being, in this last case, for distinctness' sake, appended in addition to the contradiction of those that are to be discarded. A transition to another key, which is not to continue for any length of time, is seldom indicated by a change of signature; but the sharp, flat, or natural sign is appended to any note as required, that sign affecting all the following notes of the same letter in the measure in which it occurs, unless contradicted. A sharp, flat, or natural thus introduced is called an accidental. Two accidentals are required in the ascending scale of every minor key, to sharpen the sixth and seventh of the tonic.

Besides the signature of the key, a signature of time precedes every musical composition. It consists of two figures placed over one another as a fraction, the denominator 2, 4, 8, or 16 standing for minims, crotchets, quavers, or semiquavers (i. e., halves, fourths, &c. of a semibreve), while the numerator points out how many of these fractional parts of a semibreve are contained in each measure.

Thus, indicates that there are two crotchets, and

three quavers, in the measure. When there are four crotchets (or a semibreve) in the measure, it is usual to write instead of .

SIGNATURE, in Printing, denotes the letters which are placed at the bottom of the first page of each sheet of a book, to facilitate the arrangement of the several sheets in the volume. The letters employed are those of the alphabet, with the exception of J, V, and W, three letters which have been invented since the use of signatures was introduced. See ALPHABET. As the first sheet of a work, containing the title-page, dedication, preface, &c., is generally printed last, the letter A is reserved (along with small letters, *a*, *b*, &c., should there be more sheets of introductory matter) for this and the signatures commence with B; after reaching Z, they commence again at the beginning of the alphabet, the letter being doubled for the sake of distinction, as AA, or A*a*, or more frequently 2A. Should the alphabet again be exhausted, 3A, 3B, &c., are next employed, and so on. This is the method employed in Britain; in France and Italy, figures are generally used. Signatures (as B2, B3, &c.) are also placed on certain pages of the same sheet, as a further direction to the bookbinder.

SIGNET, in England, one of the seals for the authentication of royal grants. Prior to 1848, all letters-patent and other documents which had to pass the Privy Seal, required first to have the signet affixed, and passed from the Signet-office to the office of the Privy Seal in the form of signet bills, verified by the signet-seal and superscription and the signature of the Clerk of the Signet. By act 11 and 12 Vict. c. 82, however, warrants under the royal sign-manual, countersigned by one of the principal secretaries of state, have been made *per se* sufficient authority for the Privy Seal to be affixed, and the Signet-office has been abolished. The signet in Scotland is a seal which seems to have been originally intended to authenticate royal warrants connected with the administration of justice. The principal class of agents or attorneys in Scotland are called Writers to the Signet, it is said from their having been originally clerks in the office of the Secretary of State, by whom writs passing the signet were prepared. See WRITERS TO THE SIGNET.

SIGNING, SEALING, and DELIVERY of a deed in English Law, is the mode of executing a deed. The main acts are, however, the sealing and delivery, for signature is not absolutely essential—at least in some kinds of deeds known to English law. The use of the seal is an ancient form of authenticating deeds, still kept up in England, though long superseded in Scotland by simple subscription. In practice, a wafer or seal is attached to the end of the English deed, and the party who executes it must, after signature, put his finger on the seal, and say: 'I deliver this as my act and deed,' at the same time handing the deed to the person who is to have the custody thereof.

SIGN-MANUAL, ROYAL, the subscription of the sovereign, which must be adhibited to all writs which have to pass the Privy Seal or Great Seal. When attached to a grant or warrant, it must be countersigned by one of the principal secretaries of state, or by the Lords of the Treasury. The sign-manual, in practice, consists but of the initial of the sovereign's name, with the letter R. added, for *Rex* or *Regina*.

SIGOURNEY, MRS. LYDIA HUNTLEY (Huntley being her maiden name), American authoress and poet, was born at Norwich, Connecticut, in 1791. She was, like most young ladies of ability in New England at that period, early engaged in teaching, and much of her early writings consist of tales, essays, instructive letters, and poems, for her pupils and the young. Her first published work was a volume of poems in 1815. In 1819, she was married to Mr. Charles Sigourney, a merchant of Hartford. In 1822, she published a descriptive poem on the *Traits of the Aborigines of America;* and in 1824, a *Sketch of Connecticut Forty Years Since*. These were followed by *Pocahontas and other Poems, Lays of the Heart, Tales in Prose and Verse*, &c. In 1840, Mrs. S. visited Europe, and on her return, with a freedom common to American authors, wrote her *Pleasant Memories of Pleasant Lands*. She compiled amusing and instructive books for the young, and was a constant contributor to magazines and other periodicals of poems, whose subjects, style, and sentiment gave her the designation of 'the American Hemans.' She died at Hartford, June 1865.

SIHU'N. See JAXARTES.

SIKHS. The term Sikh, a corruption of the Sanscrit *s'ishya*, signifying 'disciple,' is applied to a community of which the Punjab, in Northern India, constitutes, substantially, the confines. Less commonly, even among themselves, the members of this community are also known as Sinhs (vulgarly Singhs), that is, 'lions,' a title given them by Govind, the last and most influential of their hierarchs. Every name of a Sikh male now terminates with the word Sinh.

Originally a body of mere religionists, the Sikhs, what from the energy which they developed under repression, and the inducements to join them which they offered as proselytisers, grew, by degrees, in strength and numbers, and ended in a formidable nationality. Their originator, Nânak, was born in 1469, in the vicinity of Lahore, and died in 1539, not far from the place of his nativity. To him succeeded, in turn, nine pontiffs, each of whom, like himself, is popularly denominated guru, or 'teacher.'. These were Angad, Amardâs, Râmdâs, Arjunmall, Hargovind, Harrây, Harkrishna, Teghbahâdar, and, finally, Govind.

The aim of Nânak was pointedly humanitarian, and designed to combine Hindus and Mohammedans, at the cost of what he held to be only unimportant compromise, into one harmonious brotherhood. Sufficient proof of the comprehensive character of his scheme is afforded by the circumstance that he accepted concurrently the incarnations of Neo-Brahmanism and the mission of the Arabian prophet. His three immediate successors, while zealously protecting the interests of the infant sect, avoided secular pursuits, and held themselves aloof from political complications. Arjunmall, however, not content with signalizing himself as compiler of the *Adigranth*, and as founder of Amritsar, the holy city of the S., engaged with ardor in trade, and rendered himself conspicuous as a partisan of the rebellious Prince Khusrû, son of Jahângîr. Hargovind, who came after Arjunmall, called the S. to arms, led them in person to battle, and, though he remitted nothing of his assiduity as a guru, became an active and useful, though sometimes refractory, adherent of the Great Moghul, against whom his predecessor had plotted. Harrây subsequently espoused the part of Dârâ Shukoh, when contending with his brothers for the throne of India. Harkrishna, son of Harrây, died a child, and was only nominally a guru. Teghbahâdar, after a career of turbulence, was executed as a rebel, by command of Aurangzeb, at Delhi. However deficient in the qualifications demanded for spiritual leadership, it can scarcely be doubted that he contributed, to an important degree, in preparing for the complete change of Sikhism which was effected by his son, Govind.

The chief motive that instigated Govind, the tenth of the 'teachers,' to bring about this change was, with some probability, a desire to avenge the ignominious death of his father. He resolved to combat the Mohammedan power and, in deviation from the principles enunciated by Nânak, the Mohammedan religion as well. But Hinduism, with its social restrictions of caste, its fantastic fictions, and its irrational idolatry, likewise fell under his ban. God, he inculcated, is not to be found save in humility and sincerity. In what measure he was a man of thought is evinced by his legacy to his co-religionists, the second volume of the Sikh scriptures. A Sikh, it is therein taught, is to worship one God, to eschew superstition, and to practise strict morality, but equally is to live by the sword. The purport of this last injunction is unmistakable. Govind was assassinated, while in the imperial service, in 1708, on the banks of the Godâvarî. He died, it is true, without beholding the fulfilment of the purpose for which he had striven; but he had, nevertheless, succeeded in stirring his followers to an ambition for political independence—an idea which was ultimately transformed into a reality. His successor, but only as a temporal leader, Banda, suffered a cruel death. He did but little to advantage his sect; and his memory is not held in reverence.

With the decline of the Moghul Empire, the might of the S., in spite of their intermittent reverses, steadily increased, until, in 1764, they convened a general assembly, formally assumed the character of a substantive nation, and issued coin from which the name of the emperor was omitted. Their commonwealth was still denominated, as it had been by Govind, Khâlsa; and the component states of the federation, ordinarily said to have been twelve in number, were thenceforward distinguished as Misls. Foremost in influence among these states was that of Sukarchakiyâ, the chieftain of which was Mahâ Sinh, for whose son, the famous Ranjit Sinh (Runjeet-Singh, q. v.), it was reserved to consolidate the Misls into a unity subject to his own undivided control. The virtual headship of Ranjit Sinh dates from the year 1805, though it was not until 1838 that he attained the zenith of his ascendency. He died in the year following, at the age of 59. During 1845 and 1846, the S. ceased to exist as a nation; and their country has since been ruled by the English. Yet every loyal Sikh is still confident that his people is suffering but a transitory depression, and that it is destined to retrieve, and even to surpass, its bygone glory. In the meantime, the reputed son of a wife or concubine of Ranjit Sinh, Dilip Sinh, is a pensioner of the British government, has professed Christianity, and has taken up his abode in England.

Ethnologically considered, the S. are, in large proportion, of Jât origin; the Jâtas, whom some take to be one with the classical Getæ, being a tribe extensively diffused over the north of India. But other Hindus have helped to swell their ranks, and also not a few Mohammedans. The ten gurus are accounted Kshatriyas, or of the second Brahmanical caste, the martial. The descendants of these several races, from intermarriage and other causes, cannot, however, now be discriminated; and there is no division of the multiform population of India that strikes more than the S., as respects physical uniformity. For symmetry and comeliness,

and, it may be added, for courage and powers of endurance, the Lions of the Punjab are altogether remarkable.

Nânak's was, undoubtedly, by far the most successful of the repeated attempts which have been made to fuse together the incompatible dogmas of Hinduism and Islamism. None of the authors of these attempts seem, indeed, to have been acquainted with other than the mere surface of the two religions which they would have blended into one. With the Mohammedan, the existence of the Deity as a pure spirit, and his creatorship of the world, are fundamental postulates. On the other hand, the radical doctrine of the Hindu is pantheism, agreeably to which the universe, alternatively God, is a single eternal substance, under the twofold aspect of spirit and matter. These sets of first principles, which Nânak and his fellow-reformers could never have clearly apprehended, are palpably impossible of reconciliation.

Without rejecting all that is distinctive of his creed, no Hindu can assent to the theology of Islam; and, conversely, every intelligent follower of the Arabian prophet must be aware that the monism and the metempsychosis of Brahmanism are utterly antagonistic to the leading positions of his own faith. Govind, as we have seen, openly repudiated the notion of amalgamating Hinduism and Mohammedanism. An opportunity of becoming acquainted with his real views and those of Nanak in their fullness, has been provided for English readers by Dr. Trumpp's translation (London, 1877) of the *Adigranth* (the Original Record). The *Granth* contains also extensive quotations from Kubir and other predecessors of Nanak. A second *Granth*, by Guru Govind Sinh, has not yet been translated. These voluminous compositions are metrical throughout, and are in an archaic Indian vernacular, older than Hindi and Panjabi. They are written in the same character as the Sanscrit, the values of the letters being altered, though their forms are retained.

Among the numerous divisions into which Sikhism, as a system of belief and practise, has ramified, two, at least, apart from the great central sect, deserve specification. First are the Udâsîs, professors of indifference to mundane concerns; a sect whose origin is attributed to S'rîchand, a son of Nânak. These recluses, whom Amardâs refused to recognize as genuine S., have, to this day, numerous disciples. The Akâlîs sprang up just after the time of Govind. For extravagance of fanaticism, these Ishmaelites have, it is hoped, no rivals; and the style of their piety is comparable with that of a Thug.

As specimens of the superstitions of the S., it may be noted that, like the Hindus, they look upon the eating of beef as a deadly offence, and that, like the modern followers of Zoroaster, they attach sinfulness to the act of extinguishing a light with the breath. Some illustrations of practical Sikhism may also be gathered even from the few remarks that have been made touching the gurus. It is not irrelevant to add, that Amardâs humanely discountenanced the cremation of widows, and that Arjunmall committed suicide. The morality of ordinary S. is as positively maintained by one class of writers as it is denied by another. Evidence should seem to show that the agriculturists among them are much on a par, as to correctness of life, with other Indian cultivators of the soil. As to their soldiers, however, it has been observed that they are deeply tainted with those repulsive impurities for which the Persians are so infamous. Though forbidden the use of tobacco, they are under no restrictions as concerns indulgence in bhang, opium, and intoxicating drinks; and it would be gross flattery to commend them on the score of sobriety. As regards morality, there is reason to believe that they have greatly degenerated since the days of Govind.

The gross Sikh population has been most variously estimated by different statisticians, some of whom compute it at considerably less than half a million of persons, while others deem a million and a quarter, or even a million and a half, to be not excessive.

For the most satisfactory extant treatment of the subject of this article, the reader is referred to Captain J. D. Cunningham's *History of the Sikhs;* Sir J. Malcolm's *Sketch of the Sikhs; The Asiatic Researches*, vols. i. and xi.; the collective works of Professor H. H. Wilson, vols. i. and ii.; *The Calcutta Review*, vols. xxxi. and xxxiii.; and Dr. Trumpp's *Die Religion der Sikhs* (1881).

SIKH WARS, two brief but desperate contests waged between the British power in India and the Sikhs in 1845—1846, 1848—1849, which resulted in the destruction of the latter as an independent nation. The first had its origin in the dissensions which convulsed the Sikh country after the death of Runjeet Singh (q. v.), and which necessitated the exercise of a wary regard on the part of the Calcutta authorities. At length an army of Sikhs, flushed with their triumph over all lawful authority in their own country, crossed the Sutlej, and extended their ravages over British territory; but their advance guard was met by Sir Henry Hardinge, the governor-general, at the head of four regiments of infantry and one of dragoons, and routed at Mudki (q. v.) with heavy loss. Three days after, their main body, which had meantime crossed the river, and intrenched itself at Feroze-Shah (q. v.), was attacked by a larger force of British under Gough and Hardinge, and after a bloody conflict which lasted two days, also routed.

Still undismayed by these reverses, they again intrenched themselves at Sobraon; but a fresh body which had just crossed the Sutlej at Aliwal (q. v.), 19,000 strong, with 68 pieces of cannon, was wholly routed and driven across the river by Sir Harry Smith, at the head of 7,000 men, with 32 guns; and their main body was soon after similarly dispersed at Sobraon (q. v.). The British then crossed the river, took Lahore, and restored the authority of the young Maharjah, from whom they took the territory between the Beas and the Sutlej, the treaty confirming this settlement being made at Lahore, 9th March 1846. But the internal disturbances in the kingdom of Lahore soon became as active as before, and induced the Maharajah's prime-minister to put the country under the Company's protection; and a residency with a guard of regular troops was then established in the capital. On April 20, 1848, two British officers were murdered by a Sikh chief, the dewan Moolraj of Multan; and as this was found to be but a premonitory symptom of a general outbreak, a small force of British under Lieutenant Edwardes, aided by a body of Sikhs, under the Rajah of Bhawalpûr, gallantly attacked the army of Moolraj, which, after a desperate conflict of nine hours, they defeated on June 18, and, both sides in the meantime having received reinforcements, again on July 1. Multan was then laid siege to, but the defection of 5000 auxiliary Sikhs under Shere Singh (the son of the Sirdar Chuttur, Singh, the governor of Hazara, who had been for some time in revolt, and had driven the British from his district) compelled the British to retreat.

For some time, the British authorities in the Punjab were hampered by a want of military force, and though the Maharajah and much of his army still opposed the Sikh rebels, little reliance could be placed upon most of it. Shere Singh now succeeded in raising his army to 40,000, but was defeated by Lord Gough at Ramnugger (November 22). The inconsiderate haste of Gough at Chillianwalla (January 13) nearly lost him that great battle, which was saved only by the extreme valor of his soldiers; but amends for this fault was made at Gujerat (q. v.), where the power of Shere Singh and his allies was completely broken. Meanwhile, the fortress of Multan had, after a protracted bombardment, been captured; and the Company, seeing no other mode of protecting their territories from annoyance by these warlike fanatics, annexed the Punjab, March 29, 1849, thus terminating the existence of the Sikhs as an independent nation.

SI-KIA'NG, or WESTERN RIVER, a river at the southern extremity of China Proper. It is navigable for vessels not drawing more than 16 feet of water for about 100 miles from its mouth. The S. is remarkable for the purity and clearness of its waters.

SI'KKIM, a small protected state in the northeast of India, bounded on the W. by Nepaul, and on the S. E. by Bhotan. Area, 2544 sq. m.; pop. 50,000.—The district immediately to the south, of which Darjeeling (q. v.) is capital, is often called BRITISH SIKKIM. It was mostly taken from the Rajah of S. in 1850, in punishment of an outrage on British subjects.

SILE'NE, a genus of plants of the natural order *Caryophillaceæ;* with a tubular 5-toothed calyx; five notched or bifid petals, which terminate in a narrow claw at the base, spring from the stalk of the germen, and have each an appendage forming a *Corona* (q. v.) in the mouth of the corolla; ten stamens; three styles; the capsule 3-celled, 6-toothed, many-seeded. The species are numerous, mostly natives of the temperate parts of the northern hemisphere, annual and perennial plants; nine or ten of them natives of Britain, and others frequent in flower-gardens.—One of the most common British species is the BLADDER CAMPION (*S. inflata*), a perennial, which grows in cornfields and dry pastures, and near the sea-shore, has a branched stem fully a foot high, ovate-lanceolate bluish-green leaves, panicles of white flowers, and an inflated calyx, with a beautiful network of veins. The young shoots are sometimes used like asparagus, and have a peculiar but agreeable flavor, somewhat resembling that of peas. They are best when most blanched. The cultivation of this plant was long ago strongly recommended, but it has not obtained a place among garden plants.—The MOSS CAMPION (*S. acaulis*) is a pretty little plant, with beautiful purple flowers growing in patches so as to form a kind of turf, one of the finest ornaments of the higher mountains of Scotland, and found also in Cumberland and Wales.—Many species, some of them British, are popularly called CATCHFLY, from their viscidity, as *S. Anglica*, a species found in sandy and gravelly fields in many parts of Britain.

SILE'NUS, son of Pan and Gæa (the Earth), is generally represented as the chief of the Sileni or older Satyrs (q. v.), and the inseparable companion of Bacchus, with whom he took part in the contest against the Gigantes, slaying Enceladus. In most respects, he seems to have resembled the other satyrs, and to have borne

a strong likeness to Sir J. Falstaff, being in addition noted for his wisdom and his power of prophecy. S. had a temple at Elis.

SILE'SIA, a province of the kingdom of Prussia, included in the limits of the German empire, lies south of the provinces of Brandenburg and Posen, and is bounded on the E. by the Polish provinces of Russia and Austria, and on the S. and W. by the Austrian provinces of Silesia and Bohemia, and the kingdom of Saxony. It is divided into three governments: *Liegnitz*, in the west; *Breslau*, in the east; and *Oppeln*, in the south; and these, again, are subdivided into circles. Area, 15,666 English sq. m.; pop. (1871) 3,707,144, of whom 1,896,136 were Catholics, 1,760,341 Protestants, and 46,629 Jews; (1880) 4,007,925. Of the population, ⅛th speak Polish, more than 90,000 employ other Slavic dialects, and the rest use the German language. This province, the largest and much the most populous of the Prussian provinces, is crossed from north-east to south-west by a broad strip of mountainous country, which widens out at each extremity; and along the whole eastern boundary, and in the south, are ranges of low hills; in the north-west and center, the surface is flat and heathy, or sandy, with numerous stagnant pools.

S. is almost wholly included in the basin of the Oder (navigable as far south as Ratibor), which flows through it from south-east to north-west, and receives from each side numerous tributaries; but a small portion in the extreme south is drained into the Vistula, which here takes its rise. The soil is altogether fertile and well cultivated, more so, however, in Lower than in Upper S.; and cereals of all kinds, oil-plants, beet, hops, occasionally vines, and above all, flax and hemp, are the crops of the province; but of late years the cultivation of tobacco, and of plants yielding dyestuffs, has been receiving increased attention. Cattle and sheep, the latter excellent in quality, and partly of pure and mixed merino blood, are reared in the high-lands, the annual produce of wool averaging fully 140,000 cwt. The mines of S. are of great importance; iron, copper, and lead are the chief products; coal is found in abundance. The manufacture of lace, averaging in annual value £1,500,000, is carried on in the mountainous districts, chiefly around Schweidnitz; and the production of other fabrics, as linen, cotton and woollen goods, paper, iron, leather, glass, and earthenware, is vigorously carried on throughout the province The Oder, and the great central railway from Berlin and Posen to Vienna, afford ample facilities for commerce. There are a university at Breslau, gymnasia in the principal towns, and a great number of professional and industrial schools.

S. was inhabited at the beginning of the Christian era by the Quadi and Lygii, who, like the other German tribes, advancing westward in the 6th c., were succeeded by Slavic tribes. It formed part of the Slavic kingdom of Moravia, was next joined to Bohemia, and in the beginning of the 10th c. to Poland. In 1163, it was separated from the kingdom of Poland, but was ruled by dukes who were of the royal line of Piast; these dukes, to repeople the country, which had been devastated by the numerous civil wars, encouraged the settlement of German colonies, especially in Lower Silesia. The practice of division and subdivision of territory prevailed so extensively in S., that at one time it had no less than 17 independent dukes, and to save itself from re-incorporation with Poland, it acknowledged the sovereignty of the kings of Bohemia, with which, and with Germany, from the time of the Emperor Karl IV., it was indissolubly connected. In 1537, the Duke of Liegnitz, one of the numerous Silesian princes, entered into an agreement of mutual succession (*Erbverbrüderung*) with the Elector of Brandenburg, on the extinction of either reigning line; and the other ducal lines becoming gradually extinct, their possessions fell to Liegnitz or to Bohemia, or lapsed to the emperor.

In 1675, when the last ducal family, that of Liegnitz, failed, its territories of Liegnitz, Brieg, and Wohlau, would have fallen to Prussia, but the emperor of Germany refused to recognize the validity of the agreement of 1537, and took possession of the Liegnitz dominions, as a lapsed fief of Bohemia. The remainder of S. was thus incorporated into the Austrian empire. In 1740, Frederick II. of Prussia, taking advantage of the helpless condition of Maria Theresa of Austria, laid claim, on the strength of the agreement of 1537, to certain portions of S.; and without declaring war, marched into, and took possession of the province, maintaining his hold despite the utmost efforts of Austria in 1740—1742, and 1744—1745, called the *first* and *second* Silesian wars. After the *third* Silesian war, better known as the SEVEN YEARS' WAR (q. v.), it was finally ceded (1763) to Prussia.

SILESIA, AUSTRIAN, a duchy and crownland of the Austrian empire, bounded on the N.E. by Prussia, and on the S.W. by Moravia. Area, 1980 sq. m.; pop. (1876) 558,196. It is mountainous in the west, where the Spieglitzer Schneeberge, a summit of the Sudetic chain, rises to the height of 4512 feet. The crownland comprises 1806 sq. m. of level land, of which by far the greater portion is arable or under wood. The climate, though rough, is healthy, and the soil produces good crops of rye, oats, barley, flax, &c. Within the crownland rise the Oder and Vistula. Cattle-breeding and bee-keeping are important branches of industry; 110,000 head of sheep belong to the crownland. Iron, lead, and coal mining are profitably pursued. The manufactures are principally spirits, copper and iron wares, and linen and cotton fabrics.

SI'LEX (Lat. flint), a generic name given by some mineralogists to all those minerals of which silicia is the principal ingredient. See QUARTZ.

SI'LHOUETTE, the name given to a profile or shadow-outline of the human figure, filled in of a dark color, the shadows and extreme depths being sometimes indicated by the heightening effect of gum or some other shining material. This species of design was known among the ancients and was by them carried to a high degree of perfection, as the monochromes on Etruscan vases amply testify; but the name S. is quite modern, dating from about the middle of last century. It was taken from Etienne de Silhouette, the French minister of finance in 1759, who, to replenish the treasury, exhausted by the costly wars with Britain and Prussia, and by excessive prodigalities, inaugurated numerous reforms, and the strictest economy of expenditure. His extreme parsimony in all finance matters made him a choice subject for caricature; so that any mode or fashion that was plain and cheap —'surtouts' without plaits, trousers without pockets—was styled *à la Silhouette;* and profiles made by tracing the shadow projected by the light of a candle on a sheet of white paper being then much in vogue, have continued to bear the name. Although without merit as a work of art, the S. presents a clear and well-marked profile and such instruments as the Pantograph (q. v.), &c., used to be frequently employed to obtain profiles of a reduced size direct from the human features—Profiles cut out of black paper with scissors also receive the name of silhouettes.

Silhouette of Robert Burns.

SI'LICA. See SILICON.

SI'LICON, or SILI'CIUM (sym. Si, eq. 14 (in new system, 28), spec. grav. 2·49), is one of the non-metallic elements (see CHEMISTRY). It may be obtained in three different forms—viz., the *amorphous*, the *graphitoid*, and the *crystalline*. It is the first of these, the amorphous silicon, which is obtained by the processes in common use, the second and third being obtained from this first modification.

Amorphous silicon presents the appearance of a dull brown powder, which adheres to the finger, is insoluble in water and in nitric and sulphuric acids, but readily soluble in hydrofluoric acid, and in a hot solution of potash. It is a non-conductor of electricity, and when heated in air or oxygen, its external surface burns brilliantly, and is converted into silica, which fuses from the extreme heat, and forms a coating over the unburned silicon. *Graphitoid* silicon is obtained by exposing the amorphous variety to an intense heat in a closed platinum crucible. This form of silicon will not take fire when heated in oxygen gas, and resists the solvent action of pure hydrofluoric acid, although it rapidly dissolves in a mixture of nitric and hydrofluoric acids; moreover, as another point of difference, it is a conductor of electricity. For the description of *crystallized* silicon, we may refer to a treatise by Deville (in the *Ann. de Chimie*, 3d ser. vol. 49, p. 65), who obtained it in regular double six-sided pyramids of a dark steel-gray color.

Silicon, in a state of combination with oxygen, is the most abundant solid constituent of our globe; and, in less proportion, is an equally necessary ingredient of the vegetable kingdom, while in the animal kingdom it occurs in mere traces, except in a few special cases. It is never found in nature except in combination

with oxygen; but by a somewhat difficult process—which we need not here describe—it may be separated as a dark brown powder. It was first isolated by Berzelius in 1823. For our knowledge of the other modifications, we are indebted to Wöhler and Deville.

Silicon forms two oxides, one of which is only known in the hydrated state, while the other is the well-known compound, silica or silicic acid. *Hydrated oxide of silicon* is represented by the formula $2HO,3SiO$, and silicic acid by SiO_2. The hydrated oxide exhibits many interesting chemical properties, but is of no practical importance.

Silicic acid or *silica* exists both in the crystalline and in the amorphous form. The best examples of the crystalline form are rock-crystal, quartz, chalcedony, flint, sandstone, and quartzose sand. Silicia in this form has a specific gravity of about 2 9, and is only attacked with difficulty by potash or hydrofluoric acid. The amorphous form exists naturally in opal, and is obtained artificially as gelatinous silica, &c.; it differs from the former in its specific gravity, being about 2·2, and in its being rapidly dissolved by potash and by hydrofluoric acid.

Pure silica (as it occurs in rock-crystal, for example) is perfectly transparent and colorless, and is sufficiently hard to scratch glass. The heat of the oxyhydrogen blowpipe is required for its fusion, when it melts into a transparent glass, capable of being drawn out into elastic threads. Perfectly pure silica in its amorphous form may be obtained by various chemical processes. If a solution of silicate of potash or soda be treated with hydrochloric acid, the silicic acid separates as a hydrate, and on evaporating this to dryness, and treating it with boiling water, silicic acid remains as an amorphous powder, which, after being washed, dried, and exposed to a red heat, may be regarded as chemically pure. The hydrated silicic acid mentioned in the above experiment is soluble in water, and (more freely) in acids and alkalies. The solubility of hydrated silicic acid in water, accounts for the presence of silicic acid in mineral springs, and in the Geysers of Iceland, as well as for its gradual separation from these waters in the form of petrifactions. That silica or silicic acid is a true acid (although a feeble one), is obvious from its uniting with bases, especially those which are capable of undergoing fusion, and forming true salts, known as silicates. These silicates occur abundantly in nature; all the forms of clay, felspar, mica, hornblende, augite, serpentine, &c., being compounds of this description. Silicic acid combines with bases in various proportions.

The following table, borrowed from Miller's *Elements of Chemistry*, vol. ii., shows the combinations which are of the most usual occurrence:

	Examples.	Formulæ.
$2MO,3SiO_2$, or Sesquisilicates.	Silicate of lime	$2CaO.3SiO_2$.
	Meerschaum (hydrated silicate of magnesia)	$2MgO.3SiO_2 + 2HO$.
MO,SiO_2, Neutral silicates.	Wollastonite (silicate of lime)	$CaO.SiO_2$.
	Dioptase (hydrated silicate of copper)	$CuO,SiO_2 + HO$.
$2MO,SiO_2$, Dibasic silicates.	Olivine	$2(Mg.Fe)O,SiO_2$.
	Iron forge cinder	$2FeO,SiO_2$.
$MO,2SiO_2$, Bisilicates	The composition of many of the ordinary varieties of glass may be approximately represented by mixtures of different silicates which have this formula.	

In the above formulæ, MO stands for 1 equivalent of any metallic protoxide, such as lime, magnesia, or protoxide of iron.

The following are the general characters of the silicates: Most of them are fusible, the basic silicates fusing more readily than those which are either neutral, or contain an excess of acid. Excepting the silicates of the alkalies, no silicates are soluble in water. The anhydrous, neutral, and acid silicates of the earths resist the action of all acids except the hydrofluoric.

In conclusion, we may remark that silica derives its name from *silex*, flint, of which it is the essential constituent, and that it is largely employed in the manufacture of glass, china, and porcelain. For these purposes, it is obtained in a finely comminuted state by heating flints or portions of colorless quartz to redness, and plunging them in cold water. The silica splits up into a friable mass, which may be easily ground to a fine powder. The use of silica in giving firmness and rigidity to various parts of the animal organs, is exemplified in its free occurrence in the quill-part of the feather of birds, in the shields of certain infusoria, and in the spicula occurring in sponges; while its similar use in the vegetable kingdom is seen in its more or less abundant presence in the stalks of the grasses, more particularly in the cereals and in the bamboo (where it is especially deposited about the joints, and is known as *Tabasheer*), in the equisetæ, &c.

Silicon may be made to combine with several other elements beside oxygen, but, with the exception of silicofluoric acid, these compounds are of no practical value. Thus silicon and hydrogen form a hydride of silicon, a colorless and spontaneously inflammable gas. Nitride of silicon is a bluish fibrous body, while sulphide of silicon is a white earthy powder. Silicon unites with chlorine, bromine, and propably iodine and fluorine, in two proportions corresponding to its oxygen compounds. Fluoride of silicon (SiF_2) is a colorless pungent gas, liquefiable under strong pressure, and solidifying at—220°, inflammable, and a non-supporter of combustion. It is obtained by heating powdered glass with 12 times its weight of oil of vitriol, and when a stream of this gas is transmitted through water, a reaction takes place; two atoms of water and three atoms of the fluoride of silicon yielding silicofluoric acid (HF,SiF_2), which remains in solution, and silicon, which is deposited.

A saturated solution of this acid forms a very sour fuming liquid, which does not directly attack glass, but if allowed to evaporate on it, causes erosion from the fluoride of silicon becoming evaporized, and free hydrofluoric acid being left. A dilute solution is frequently employed in the laboratory as a precipitant of potash, which it throws down in a transparent gelatinous form. With salts of baryta, it gives a white crystalline precipitate. It combines with bases to form salts, none of which are of any special importance.

SI'LIQUE (*Siliqua*), in Botany, the fruit of the *Cruciferæ*, a capsule opening by two valves, which, when ripe, separate from the base upwards, leaving a central frame (*replum*), to which the seeds remain attached, and which is regarded as formed by parietal placentas, the valves giving way close to the suture. The seeds are either in one row or two. A SILICULE (*silicula*) is merely a silique of a different form, the true silique being long and narrow, the silicule broad and short, although Linnæus made this difference the foundation of the orders (*Siliquosa* and *Siliculosa*) of his class *Tetradynamia*, a distinction not now equally attended to in the subdivision of the natural order *Cruciferæ*.

SILI'STRIA, a town of the new principality of Bulgaria, is situated on the right bank of the Danube, which is here nearly one-fourth of a mile wide, and is studded with numerous islands. The houses are mean, and built generally of wood, though sometimes of stone, and also of mud; the streets, like those of most Moslem cities, are crooked, narrow, dirty, and ill-paved; and the manufactures are insignificant, though there is a considerable trade in wood and cattle. Pop. 20,000. The Dobrudscha, ceded by Turkey to Rumania in 1878, is bounded by a line running from a point just east of S. to Mangalia on the coast. The importance of S. lay formerly in its value as a military outpost of Turkey. Its walls were constructed of solid masonry, but consisted merely of a fortified *Enceinte* (q. v.) surrounded by a ditch, the great strength of the fortress depending upon the support given to it by detached works. S. is a town of great antiquity, and was a fortress under the Byzantines. Here, in 971, the Byzantine emperor, John Zimisces, routed the Russians under Sviatoslav. It has been repeatedly assaulted and taken by the Russians. In 1849, S. was made a stronghold of the first class, and was rendered almost impregnable by the addition (1853) of 12 detached forts on the south and east. On the outbreak of the Crimean war, the Russians laid siege to it, with an army of from 60,000 to 80,000 men, but were compelled to retreat after 39 days. The Congress of Berlin in 1878, when erecting Bulgaria into a principality, decreed that the fortifications of S., like those of the other Bulgarian cities, should be dismantled.

SILK AND SILKWORM. The name *silk* is derived, by the not unusual substitution of *l* for *r*, from Lat. *sericum* (Gr. *serikon*), so called as coming from the country of the Seres or Chinese. The SILKWORM is the caterpillar of the SILKWORM MOTH, of which there are numerous species belonging to the genus *Bombyx* and other genera of the family *Bombycidæ*, lepidopterous insects of the section popularly known by the name Moth (q. v.). The *Bombycidæ* have a very short and rudimentary proboscis, living for a very short time in their perfect state, and taking little or no food; the body is thick and hairy; the wings are large and broad, either extended horizontally when at rest, or inclined like the sides of a roof; the antennæ are pectinated. The caterpillars feed on the leaves and other tender parts of trees or other plants; the chrysalids are enclosed in a cocoon of silk, which gives to some of the species a great economical importance. The most important is the COMMON SILKWORM (*Bombyx mori*), a native of the northern provinces of China. The perfect insect is about an inch in length, the female rather larger than the male; the wings meeting like the sides of a roof; the color whitish, with a broad pale brown bar

across the upper wings. The females generally die very soon after they have laid their eggs, and the males do not survive much longer. The eggs are numerous, about the size of a pin's head, not attached together, but fastened to the surface on which they are laid by a gummy substance, which, when dry, becomes silky. They are laid in the end of summer, and are hatched in the beginning of next summer.

The caterpillar is at first very small, not more than a quarter of an inch in length, but rapidly increases in size, till, when full grown, it is nearly three inches long. It is of a yellowish gray color. The head is large. On the upper part of the last joint of the body is a horn-like process. The skin is changed four or five times during the growth of the caterpillar. Before each change

Silkworm Moth (*Bombyx mori*), in its various stages.

of skin, it becomes lethargic, and ceases to eat, whereas at other times it is very voracious. When the skin is ready to be cast off, it bursts at the fore part, and the caterpillar then, by continually writhing its body, without moving from the spot, thrusts it backwards; but silkworms frequently die during the change of skin. A very rapid increase of size takes place whilst the new skin is still soft. The natural food of the silk-worm is the leaves of the white mulberry, but it will also feed on the leaves of some other plants, as the black mulberry and the lettuce. When so fed, however, it produces silk of inferior quality. The silk-producing organs are two large glands (sericteria) containing a viscid substance, which extend along great part of the body, and terminate in two *spinnerets* in the mouth. These glands become very large when the change to the chrysalis or pupa state is about to take place. When about to spin its cocoon, the silkworm ceases to eat, and first produces the loose rough fibre which forms the outer part of the cocoon, and then the more closely disposed and valuable fibre of its interior.

In this process, the position of the hinder part of the body is little changed, but the head is moved from one point to another; and the cocoon when finished is much shorter than the body, which, however being bent, is completely enclosed in it. The cocoon is about the size of a pigeon's egg. Each fibre of silk, when examined by a microscope, is seen to be double, being equally derived from the two silk-producing organs of the caterpillar. A single fibre often exceeds 1100 feet in length. The time of the silkworm's life in the caterpillar state is generally about eight weeks. About five days are occupied in the spinning of the cocoon; after which about two or three weeks elapse before the cocoon bursts and the perfect insect comes forth. The natural bursting of the cocoon is, however, injurious to the silk, and the silkworm rearer prevents it by throwing all the cocoons into boiling water, except those which he intends to keep in order to the maintenance and increase of his stock. These he selects with care, so that he may have about an equal number of male and female insects, the females being known, even in the chrysalis state, by their larger size. The cocoons intended for the production of moths are placed on a cloth in a somewhat darkened room, of which the temperature is near, but does not exceed 72° F.; and the moths, when produced, show no inclination to fly away, but remain on the cloth, lay their eggs, and die there.

It is an interesting peculiarity of this valuable species of moth, that neither in the caterpillar nor in the winged state does it show that restless disposition which belongs to many others, the caterpillars remaining contentedly in the trays or boxes in which they are placed, feeding on the leaves with which they are there supplied, and at last only seeking a proper place to assume the chrysalis form on small bundles of twigs which are placed for that purpose above the trays; the perfect moths, in like manner, abiding almost in one spot, and scarcely caring to use their wings. Owing to this peculiarity it is capable of being reared and managed in a way which would otherwise be impossible.

The silkworm is liable to various diseases, particularly to one by which great numbers are often destroyed, and which is either caused or characterized by the growth of a small fungus known as *Silkworm-rot*, or *Muscardine* (q. v.).

Of the other species of silkworm, many are rapidly increasing in commercial importance. The following is an enumeration of the chief silk-producing insects; those in Italics are not as yet employed in manufactures:

Bombyx mori.—The common silkworm, native of India, and reared in other parts of the world.

B. cræsi.—Crosses have been obtained between this and B. mori, yielding excellent silk, at Mussooree.

B. textor—Native of Mussooree.

B. sinensis.—China.

B. Huttoni.—Silk collected in Mussooree.

B. Horsfieldi.—Native of Java.

Attacus atlas.—Native of India, and said to yield some of the 'Tusseh Silk.'

A. Guerini.—Native of Bengal.

A. ricini.—Native of Assam.

A. cynthia.—The 'Eria,' or 'Arrindy' silkworm, native of India, now extensively raised in Hong-kong, Nepaul, Mussooree, Java, and to some extent in Southern Europe. It feeds on the leaves of the Ailanto (q. v.) tree.

Antheræa Mezankooria.—The Mezankooria silk-moth.

A. Paphia.—The true Tusseh or Tussur Moth, native of Darjeeling, and other parts of Upper India. It is produced very extensively, and is chiefly collected in the jungle districts by the Sahars and other half-wild castes who live in the jungles. The cocoons are so carefully concealed in the leaves, that much care is required to discover them, the only indication being the dung of the caterpillar, under the trees. The tusseh silk is easily wound off from the cocoons in the same way as that of the common silkworm.

A. Assama.—The Moonga, or Moogha, native of Assam.

A. Pernyi.—North China.

A. Perrottetti.—North China.

A. Roylei.—Mussooree.

A. Helferi.—Darjeeling.

A. Jana.—Java.

A. Frithii.—Darjeeling.

A. Larissa.—Java.

The preceding seven are all called Tusseh moths.

Actias Selene.—Darjeeling.

Saturnia pyretorum.—China.

S. Grotei.—Darjeeling.

Lœpa Katinka.—Java.

Neoris Huttoni.—Mussooree.

Caligula Tibeta.—Mussooree.

C. Simla.

Salassa Lola.—South-east Himalaya.

Cricula triferrestrata.—Java.

It will be seen by the above list that hitherto very few of the silk-moths have been turned to man's profit. The first in importance after the common silkworm is the true *Tusseh*, next, the *Moonga*, the silk from both of which can be wound off the cocoon; and then the *Eria*, which cannot be wound easily, and is therefore generally carded.

Silk appears not to have been well known to the ancients; although several times mentioned in the translations of the Bible, the best authorities deny that it is in the original, or that it was known to the Hebrews. Among the Greeks, Aristotle is the first who mentions it, and he only says that 'Pamphile, daughter of Plates, is reported to have first woven it in Cos;' and from all the evidence which has been collected, it would appear that the natives of Cos received it indirectly (through the Phœnicians and Persians) from China. The silken webs of Cos found their way to Rome, but it was very long before they were obtainable except by the most wealthy. The cultivation in Europe of the worm itself did not take place until 530 A.D., when, according to an account given by Procopius, the eggs were brought from India (China) to the Emperor Justinian by some monks.

In China, the cultivation of silk is of the highest antiquity, and according to the greatest Chinese authorities, it was first begun by Si-ling, the wife of the Emperor Hoang-ti, 2600 years B.C., and the mulberry was cultivated for the purpose of feeding them only forty years later.

Since its introduction to Europe, it has always formed a great branch of industry in Italy, Turkey, and Greece, and it has been cultivated to some extent in France, Spain, and Portugal. In England, too, from time to time, laudable efforts have been made to cultivate it, especially by Mrs. Whitby of Newlands, Mr. Mason of Yately in Hampshire, and Lady Dorothy Neville of Dangstein in Hampshire; but this branch of industry requires a warmer and less variable climate and cheaper labor than we can command. Recently, silk has been successfully cultivated in New Zealand.

The quantity of silk raised in the world is enormous. Great Britain imports annually in the unmanufactured state: 'Raw' silk, about 6,500,000 lbs.; 'waste,' or knubs and husks, about 3,500,000 lbs.; besides undyed 'singles,' about 5700 lbs.; tram, about 7000 lbs.; organzine, about 39,000 lbs.; and dyed singles and tram, about 3000 lbs.; organzine, about 10,000 lbs. Singles, tram, and organzine are terms applied to the thread after it has undergone certain operations (to be afterwards described). The

total quantity is thus about 10,000,000 lbs., of the value of £5,000,000; and in addition to this we import manufactured silk goods to the value of about twelve millions and a half sterling; so that the

Ailanto Silkworm (reduced), showing the Cocoon of Silk attached to a Leaf.

importance of this little insect to Great Britain alone is represented annually by about £17,500,000. It requires 1600 worms to raise a pound of silk.

Rearing of Silkworms.—It is of the first consequence in the production of silk that one of the species of mulberry should be cultivated, and that it should be so favorably situated as to climate, that its foliage is in readiness for feeding the young worms when they are first hatched from the eggs. The species best adapted is the white mulberry, *Morus alba*. The extreme lateness of season at which the black mulberry produces its leaves, prevents its employment generally, besides which it will not bear the loss of its leaves so well. It is said that in some parts of China the silkworm is easily reared upon the trees in the open air. So little has it a tendency to wander far from the place of its birth, if food be at hand, that it only requires a warm dry atmosphere to bring it to perfection; but usually, even in China, and in all other countries, it is thought desirable to raise the silkworm in properly arranged buildings, and to supply it with mulberry leaves gathered from day to day. In India, China, and other tropical countries, the eggs hatch readily at the proper time by the natural heat; but in Southern Europe, artificial heat is almost always required; formerly, the heat of fermenting dung was found serviceable, and the warmth of the human body was also used, the eggs being carried in little bags in the bosom of the cultivators; but now they are regularly hatched by stove-heat, beginning with a temperature of 64° F., which is gradually increased through ten days to 82°, at which it is maintained until the eggs are hatched.

Experience has shown that the operation is facilitated by washing the eggs in the first place with clean water; and some cultivators also wash them in wine, the value of which is very questionable. Washing is found to remove a certain gumminess and other impurities from the eggs, which would otherwise impede the hatching. When the silkworms have been regularly developed

Fig. 1.

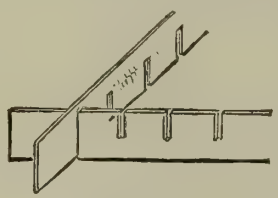


Fig. 2.

as above described, it is usual to place above the trays various little contrivances for the caterpillar to spin within: many of the Italian growers employ an ingeniously simple arrangement, which lasts many seasons, and when not in use, occupies very small space. It consists of a number of thin slips of wood, about an inch and a half broad, and all cut sufficiently long to reach across the trays. They are each cut at intervals of an inch half through,

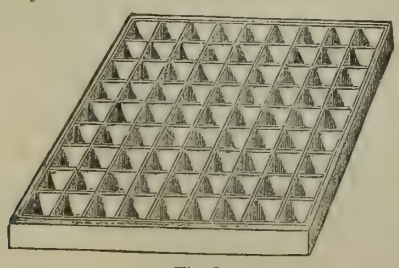

Fig. 3.

as in fig. 1, so that one will fit into another, as in fig. 2; and when complete, they all form a series of cells which, set in a tray, (fig. 3), form the very best receptacles for the silkworm to spin it. When not in use, the whole arrangement can be compressed into very small compass, as in fig. 4, for convenience of storage. Others use little cones of paper, or small twigs, amongst which the cocoons are spun.

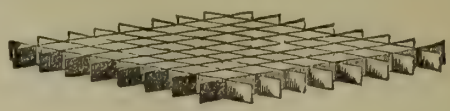

Fig. 4.

In feeding the worms, care is taken so to distribute the food on the shelves or in the trays that the insects shall not crowd together; and for this reason, the most careful cultivators chop the leaves small, and strew them very evenly about. Great care is taken not to let the worms of one hatch mix with those of another, unless of exactly the same age, otherwise the stronger insects would deprive the younger of their food. Many other niceties of attention are required, which altogether render the successful rearing of silkworms a matter of much anxiety and labor.

Fig. 5.

Fig. 6.

Preparation of Silk.—When the cocoons are completed, which is known by the absence of any sound within, they are carefully sorted, and a certain number are kept for laying. The sexes are readily known by the difference of shape as well as of size, the female being plumper, as in fig. 5, and the male (fig. 6), besides being much smaller, having a central depression and sharper extremeties. The French growers sort them into nine varieties, those which are less compact, or in which the worm has died—a fact known by external indications—being separated from the good ones.

When the sorting is finished, the cocoons are placed in an oven with a gentle heat, which kills the enclosed chrysalis, otherwise they would all become *perforated* by the insect eating through; they are then prepared for winding by first removing the flossy covering, which is often somewhat hard and compact. The cocoons are placed in basins of water, kept warm by charcoal fires, or, in the larger establishments, by steam. This softens and dissolves the natural gum which coats the silk, and makes the various coils of silk adhere together in the cocoon. The operator then takes a small branchy twig, and stirs them about in the water. This is sure to catch hold of any liberated ends which may be floating in the water. From three to five of these ends are taken and twisted together with the fingers, so as to unite them into one thread, which is passed through a polished metal or glass eye in the reeling-machine, which is so far from the hot-water basin as to give the softened gum on the silk time to dry in its passage from the basin to the reel. In large *filatures* or silk establishments, complex machinery is used for winding; but reeling apparatus of the greatest simplicity is used by the Chinese, East Indians, and others with almost equal effect, when carefully done, except in the amount of work accomplished.

In all cases, however, the principle is the same, and is very simple, as shown in fig. 7, in which *a* shows the small pan of

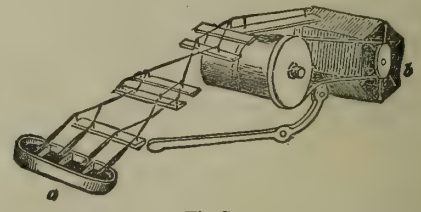

Fig. 7.

warm water holding the cocoons, the threads from which are gradually united, and wound on the reel *b*. Great care and skill are required in reeling silk from the cocoons, because, although the reeler starts with four or five cocoons, not only are their individual threads apt to break, but they are not all of the same length, so that one will run out before the others. These matters are carefully watched; and as often as a thread breaks, or a cocoon runs out, another thread is joined on, and is made to adhere to the compound thread on the reel by its natural gumminess. Each cocoon generally yields 300 yards of thread, so that it takes 1200 or 1500 yards to make 300 yards of the filament of raw silk, by which name the reeled silk is always known. The raw silk is made up into hanks of various sizes. That from China and Japan is tied in packages of six hanks each technically called *books*, and sometimes the ends of these books are covered with silken caps very curiously formed out of a single cocoon, so managed as to form a filmy cap sufficiently large to cover a man's

head. The method used by the Chinese to accomplish this is quite unknown in Europe. These caps or bags, when closed, are sometimes nearly a foot square, and much of the wadding used by the Chinese dressmakers for padding is made by placing these bags upon each other to the required thickness.

Notwithstanding the care taken in reeling the silk from the cocoons, and forming several threads into one, it is not ready for the weaver, but has to undergo the processes called collectively *throwing*. In this country, this is a special trade, the *silk throwster* usually conducting it in large mills with extensive machinery, where the above processes are all carried on generally by steam-power. The silk reaches the throwster in hanks as imported. These are put into clean soap and water, and carefully washed, ties having been placed at intervals, to prevent the silk entangling. After being dried by hanging in the drying-room, they are placed on large skeleton reels called *swifts* (fig. 8), so adjusted that they will hold the hanks tightly. Fig. 9 is a front view of a *swift*, and shows that the spokes, *a*, *a*, are in pairs. They are made of thin pieces of lance-wood, and each pair are rather nearer together at the axle than at the circumference, where they are connected together by a small band of cord, *bb*. These bands are so tied that they will slip down easily to admit of the hanks being placed; then, by pushing the cords upwards, the hank can be stretched to its fullest extent. This is necessary to compensate for the varying lengths of the hanks received from different countries.

When the *swifts* are set in motion, the silk is carried from the hanks to bobbins, upon which it is wound for the convenience of further operations. The bobbins are then taken from the *winding* to the *cleaning* machine, when they are placed on fixed spindles, so that they will turn with the slightest pull; and the thread is passed through a small apparatus attached to the machine, which is specially called the cleaner, and consists essentially of two polished smooth-edged blades of metal (*a*, *a*, fig. 10), attached to a part of the frame of the machine, *b*. They are held together by

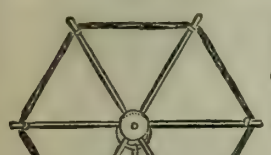

Fig. 8.

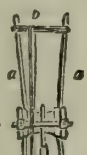

Fig. 9.

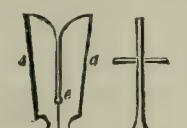

Fig. 10.

the screw *c*, and are slightly opened or closed by the other screw, *d*, so that the thread can be put between them down to the small orifice, *e*, and then, by tightening the screw, preventing its return, after passing through this small hole, which is the gauge of the thread, and which removes any irregularities or adherent dirt. The silk next passes over a glass or metal rod, and then through another small hole, much larger than that of the *cleaner*, and usually made of glass, on to the bobbin, upon which it is wound by the action of the machine. The next process is *twisting* the cleaned thread, by which it becomes better adapted for being combined with other threads.

Doubling is the next process, and this consists in running off a number of bobbins of *twisted* silk on to one bobbin of a larger size, which is put into the *throwing*-machine, when the ends of the *doubled* silk are passed through a smooth hole on to a large reel, which rewinds it into hanks, but twisting the threads into a fine cord as it goes from the bobbins to the reel. This operation of *throwing* derives its name from the Saxon *thrawan*, to whirl or twist. After this, the hanks have to be again wound on reels and bobbins for the weaver, the former for the warp, and the latter for the weft. For many purposes, only some of these operations are required. Thus for common and light fabrics, such as *Persian*, *gauze*, &c., only the two first are needed—viz., the *winding* and *cleaning*, and the material is called *dumb-singles*. If it has been *wound*, *cleaned*, and *thrown*, it is called *thrown-singles*, and is used for weaving common broad stuffs, or plain silks and ribbons. If *wound*, *cleaned*, *doubled*, and *thrown*, it is called *tram*, and is used for the richer silks and velvets, but only for the weft or shoot; and if *wound*, *cleaned*, *spun*, *doubled*, and *thrown*, it is called *organzine*, and is used for the warps of fine fabrics.

Before winding the cocoons, a flossy portion has to be removed; and after all has been wound off, another portion remains, like a compact bag; these are collected and sold under the name of *waste-silk*, and to these are added the fragments of broken threads, which accumulate in considerable quantities during the reeling and throwing operations. Formerly, very little use was made of waste-silk; not a little of it was employed by engineers and others for mere cleaning purposes; although, as early as 1671, a proposition was made by a manufacturer named Edmond Blood to make it available by carding it with teasels or rowing-cards. He took out a patent for this invention, but apparently did not bring it into use. Another patent was taken out by Mr. Lister of Bradford, which has done wonders; now the waste is all spun into yarn, thereby greatly economizing the use of silk, as the quantity of silk-waste always greatly exceeds the amount of good silk reeled off. The processes employed in the production of silk-yarn from the waste differ little from those for spinning other materials. See SPINNING.

The silk-manufactures of Britain are chiefly located in Spitalfields, London, at Macclesfield and Congleton in Cheshire, at Derby, and in Glasgow. The dyeing of silk is done chiefly in the neighborhood of London, at Nottingham, and at Manchester; and considerable quantities of silk goods are sent from India to be printed with patterns in London and other parts of England. These goods are chiefly the corah and bandana pocket-handkerchiefs, and Indian waist and turban scarfs.

SILK-COTTON. Under this name, various silky fibres are from time to time brought from tropical countries to Europe; they are all of the same general character, and are produced by the trees composing the genus *Bombax*, and other genera recently separated from *Bombax*, of the natural order *Sterculiaceæ*, known as silk-cotton trees. These trees are natives of the tropical parts of Asia, Africa, and America. The fibre fills their large woody capsules, enveloping the seeds, and is produced in great abundance; but is too short, too smooth, and too elastic to be spun by the machinery used for cotton; although attempts have been successfully made on a small scale in India to spin and weave it; and that of *Bombax villosum*, which is of a beautiful purple color, is woven into cloth and made into articles of dress in New Spain. Silk-cotton is much used for stuffing pillows, mattresses, and sofas. Sir James Emerson Tennent says it 'makes the most luxurious stuffing for them. It has the fault, however, of being easily broken and reduced to powder, but might probably be very useful in the manufacture of gun-cotton and collodion. The silk-cotton of the East Indies is imported into Britain under the name of *Moc-main*. —*Bombax ceiba*, the common silk-cotton tree of the West Indies and South America, attains a very great size, its trunk sometimes being so thick that it could not be encompassed by the outstretched arms of sixteen men, and canoes are hollowed out of it of an average burden of twenty-five tons. The wood is soft and spongy, but is used for many purposes, and when cut into planks, and saturated with lime-water, it bears exposure to the weather for many years.—*Bombax, Malabaricum*, or *Salmalia Malabarica*, is the common Silk-cotton Tree of the East Indies. It is a tall tree, covered with formidable thorns. Although it is a tropical tree, its leaves fall annually; and just before the fresh leaves appear, it is covered with crimson tulip-like flowers, so abundant, that when they fall, the ground for many roods on all sides is a carpet of scarlet.

The fibre of the capsules of *Chorisia speciosa* and *C. Pecholtiana* trees nearly allied to the genus *Bombax*, and natives of Brazil, is known as VEGETABLE SILK. It has a beautiful satiny lustre, and is very light, but no mode of spinning and weaving it has yet been invented.

SI'LKWORM GUT, a material used by anglers for dressing the hook-end of the fishing-line. It is prepared from the silkworm at the period when it is just about to spin, and the sericteria or silk vessels are distended with the secretion. The worms are immersed for twelve or fourteen hours in strong vinegar, and then taken separately, and pulled in two very gently. The skilled operator knows at sight if the soaking in vinegar has been sufficient, and if so, he lays hold of one end of the viscid secretion, which is seen in the silk glands, and attaches it to the edge of a board; the other end he stretches to the other edge of the board, and attaches it with a pin. When a number are drawn across the board, it is set in the sun for the threads to dry, when they are tied into bundles for use. They are chiefly produced in Italy and Spain.

SILL, the horizontal wood or stone base along the bottom of a window or door; also the wooden plate along the bottom of a partition.

SILLIMAN, BENJAMIN, American physicist, was born at North Strafford (now Trumbull), Connecticut, U. S., August 8, 1779. His father was a distinguished lawyer, and a brigadier-general in the War of Independence. He was educated at Yale College, New Haven, in which he was appointed a tutor in 1799, and was admitted to the bar in 1802, but soon after received from the college the appointment of Professor of Chemistry; which he accepted only on condition of visiting some of the seats of learning in Europe, to observe the progress of the science. His tour in Europe, 1805—1806, was one of the first of which an account was published in the United States. Uniting mineralogy and geology to chemistry, he made a geological survey of Connecticut, observed the fall of a meteorite; constructed, with the aid of Professor Hare, a compound blowpipe, and repeated the experiments

of Sir Humphry Davy. In 1822, he first established the fact of the transfer of particles of carbon from the positive to the negative electrode of the voltaic apparatus. In 1818, he founded the *American Journal of Sciences and Arts*, better known as *Silliman's Journal*, of which he was for twenty years the sole, and for eight more the principal editor. Besides his labors as professor and editor, he began in America the since widely-extended work of popular scientific education, by giving public lectures on his favorite sciences in all the chief cities. In 1830, he published a text-book on Chemistry, and soon afterwards edited an edition of *Bakewell's Geology*. An account of his last visit to Europe was published in 1851, and reached six editions. His last course of lectures was given in 1855, when his son, BENJAMIN SILLIMAN, jun., who had been his associate, became his successor. He died in November 1864.

SI'LLOTH, a town and watering place of England, of quite recent origin, in the county of Cumberland, at the terminus of a branch of the North British Railway, 20 miles west-north-west of Carlisle, is picturesquely situated on the Solway. The port is of growing importance, and possesses a good stone dock, with an area of five acres, having a fine jetty, 1000 feet long, projecting into the sea. S. is much resorted to for sea-bathing, the climate being mild and salubrious, and considered highly favorable for those affected with pulmonary complaints. The mean annual temperature is 49°, being the same as that of Worthing (q. v.) on the south coast of England, and only 1° below that of Torquay. According to the Registrar-general's returns, the mean average death-rate in S. for ten years is only 10·2 per 1000. S. is of easy access from all parts of England by railway, and steamers ply at stated intervals to and from Liverpool, Dublin, Belfast, and the Isle of Man.

SILU'RIAN ROCKS, a large division of the Palæozoic rocks between the Old Red Sandstone and the Cambrian strata. They comprise the greater portion of the rocks called by Werner 'transition,' because, as he thought, in their structure they exhibited an intermediate character between Lehman's 'primary' or metamorphic rocks, and the 'Secondary' or fossiliferous deposits. But the fossils peculiar to these beds having been found in rocks without the transition structure, the name has long ago fallen into disuse. The term 'grauwacke' or 'graywacke,' a miners' term, was also introduced from the Germans, and for some time employed to designate these rocks, because of the abundance in them of a compact argillaceous sandstone; but this awkward name has also given place to Silurian, a term introduced by Sir R. I. Murchison when he first established the system, and derived from the district where he investigated the strata; South Wales having of old been occupied by the Silures (apparently a non-Celtic, Euskarian tribe).

The Silurian system contains an enormous thickness of rocks, nearly 30,000 feet, according to some estimates, the absolute thickness being greatly increased by immense beds of interstratified igneous rocks. The upper limit, underlying the Old Red Sandstone, is universally accepted, but there has been considerable diversity of opinion in regard to the inferior boundary. Professor Sedgwick, having described the rocks of North Wales, which at first were considered to be older than the series which Murchison had illustrated, designated them Cambrian. This name has been retained for the immense mass of indurated shales and sandstones of a thickness nearly equal to that of the Silurians, which contain only faint traces of organic life, and underlie the Llandeilo formation. But Sedgwick claims also the Lower Silurian rocks as a portion of his system; the priority of name, and the uniform facies of the organic remains of the whole of the Silurian rocks, have, however, induced geologists to consider the limits as originally given by Murchison as those of the system.

The subdivisions of the rocks of the period are the following:

UPPER SILURIAN ROCKS.

	Thickness in Feet.
Upper Ludlow—	
1. Downton Sandstone and Tilestones	80 to 1000
2. Upper Ludlow Shale	800
Lower Ludlow—	
3. Aymestry Limestone	150
4. Lower Ludlow Shale	900
Upper Wenlock—	
5. Wenlock Limestone	300
Lower Wenlock—	
6. Wenlock Shale	1400
7. Woolhope Limestone and Denbighshire Grit	150

MIDDLE SILURIAN ROCKS.

Upper Llandovery—	
8. Tarannon Shale	1000
9. May-hill Sandstone and Pentamerus Limestone	800
Lower Llandovery—	
10. Llandovery Slates	1000

LOWER SILURIAN ROCKS.

Caradoc—	
11. Caradoc Sandstone	12,000
12. Bala Limestone	
Llandeilo—	
13. Upper Llandeilo	1500
14. Lower Llandeilo or Arenig Beds	
Contemporaneous Volcanic Rocks	5800

The typical Silurian strata are in Wales, and the adjoining English county, Shropshire. With the exception of the southern and south-eastern districts, where the Old Red Sandstone and Coal Measures occur, the whole of Wales is composed of Silurian and Cambrian rocks. The same deposits are found in Cumberland and the north of Lancashire. The whole of Scotland south of a line drawn from Dunbar on the east to Girvan on the west, consists of graywacke rocks, slates, and limestones of Silurian age, with the exception of one or two small patches of Old Red, Carboniferous, and Permian strata. The rocks, till recently referred to an azoic group, below the lowest fossiliferous strata in the north of Scotland, are now generally believed to be highly altered beds of this period. The southern boundary of these beds is a line drawn from Stonehaven to Helensburg. A huge trough, filled up with Old Red Sandstone and Carboniferous strata, separates the highly altered strata of the north from the less altered deposits of the south. An extensive region of Silurian rocks occurs in the south-eastern counties of Ireland and in Galway; and a great track of the same beds extends from the center of Ireland (Cavan, &c.) to the coast of Down. The metamorphic rocks of the north-west are most probably also of the same age as the corresponding strata in the north of Scotland.

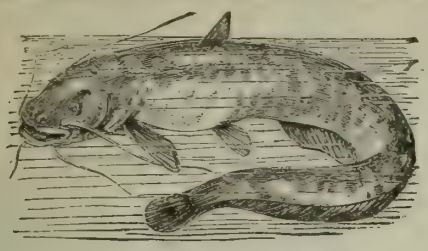
On the continent, Silurian strata have been examined and correlated with the British types, in Bohemia, by M. Barrande; in Scandinavia, by M. Angelin; and in Russia, by Murchison and others. In North America, also, extensive regions are covered with these strata. They have been wrought out and their fossils described by the Canadian and United States surveyors. Similar strata have also been detected in India, Australia, and South America.

The life of the period presents a group of very characteristic organisms, which, with the exception of the fish-remains found in the upper beds, all belong to the invertebrata. Many of them are confined to the Silurian rocks, or occur only very rarely in some of the Palæozoic formations. The Graptolites are a strictly Silurian family of Zoophytes, and most of the forms of Trilobites are found only in this period, though some members of the tribe are found in rocks of Devonian and Carboniferous age. Besides these, may also be specified such forms as Heliolites and Favosites among the Corals; Actinocrinites and the Cystidians among the Echinoderms; Orthis and Lingula among the Brachiopods; and Lituites and Maclurea among the Cephalopods.

In all the immense thickness of Silurian rocks, no deposit has been discovered containing organisms that have lived on land. Some fragments have been noticed that have a faint resemblance to the branches of Lepidodendron, and minute bodies occur in the bone-bed, which are referred to the spores of a terrestrial cryptogam. The only other indications of plants are impressions believed to have been produced by sea-weeds. The anthracitic shales of Wales and Scotland probably derived their anthracite from the algæ that must have abounded in the Silurian seas. In Shropshire, a number of shells have been found, whose nearest allies are littoral species, and these appear to indicate the existence there of an ancient shore. The Silurian rocks are, however, generally sea-deposits, and Forbes has ingeniously shown, from the small size of the conchiferæ, the paucity of spiral univalves, the great number of floating shells and of the pelagic Orthidæ, and the great rarity, or absence, except in the upper beds, of fossil fish, that it is most probable they were deposited in a sea more than 70 fathoms deep.

SILU'RIDÆ, a family of malacopterous fishes, divided into many genera, and including a great number of species, mostly inhabitants of the lakes and rivers of warm countries. The S. exhibit great diversity of form. Their skin is generally naked, but some have a row of bony plates along the lateral line, and a few are completely mailed with bony plates. The dorsal fin is single in some; others have two dorsal fins, the second being sometimes adipose, as in the salmon family. The dorsal fin is sometimes armed with a strong spinous ray, and in most of the family the first ray of the pectoral fins is very strong and serrated, so as to be capable of inflicting a severe wound, and by this these fishes are protected from alligators and other enemies. All have the mouth furnished with barbels, more or less numerous; the two principal barbels being on the upper lip, and formed by elongation of the intermaxillary bones. The barbels are believed to be organs of touch, probably of use in directing the fish to its prey. The bones of the head and other parts of the skeleton exhibit many peculiarities, into which we cannot enter. The S. are gen-

erally inhabitants of muddy rivers, lurking amongst the mud. The only European species is the SLY SILURUS, SHEAT-FISH, or SHADEN (*Silurus glanis*), the largest of European fresh-water fishes, and sometimes found in the sea near the mouths of rivers. It does not inhabit any of the rivers of Britain; its introduction has, however, recently been attempted. Neither is it found in France, Spain, or Italy, but it is plentiful in the Danube, the Elbe, and their larger tributaries, also in the rivers which fall into the Caspian Sea; and it is found in some of the rivers of North



Sly Silurus (*Silurus glanis*).

America. It attains a length of six or even eight feet, and a weight of 300 or 400 pounds. The flesh is white and fat, but soft, luscious, and not very easily digestible. In the northern countries of Europe, it is preserved by drying, and the fat is used as lard. The habits of the fish are sluggish; it seems rather to lie in wait for its prey than to go in quest of it.—Several species of this family are found in the Nile, among which is the HARMOUTH or KARMOOT (*Clarias anguillaris*), a fish in its general form and appearance much resembling that just described. It was anciently an object of superstitious regard in the Thebaïd.

SI'LVAS, or SELVAS (Span. *selva*, a forest), the name given to the western portion of the great plain of the Amazon, in the north-west of Brazil. The Silvas, which are about one-third of the whole plain, contain more than 700,000 English sq. m., and consist of low land on a dead level, densely covered with primeval forests, and annually inundated by the overflow of the mighty river or its tributaries. The forests are rendered wholly impenetrable from the denseness of the underwood, matted together as it is by creeping and climbing plants, which form myriads of festoons glowing with nature's brightest tints. The vegetation of the Silvas, under the stimulating action of the abundant irrigation, the intense tropical heat, and the inconceivable richness of the alluvium which constitutes the soil, shows an exuberance of growth far surpassing that of any other portion of the earth's surface, and from its very luxuriance, presents a bar to civilization no less effectual than do the barren deserts of Africa or the gloomy wastes of Central Asia. The few Europeans who have penetrated into this region have sailed up the Amazon and some of its tributaries, and from them we have received the little knowledge that we do possess of this immense tract of wild forest. It is the haunt of innumerable wild animals, especially monkeys and serpents, and of a few aboriginal inhabitants, who are sunk in the lowest stage of barbarism.

SILVER (symb. Ag, equiv. 108. sp. gr. 10·53) is a metal which, in its compact state, is of a brilliant white color, possesses the metallic lustre to a remarkable degree, is capable of being highly polished, and evolves a clear ringing sound when struck. It is harder than gold, but softer than copper, and is one of the most ductile of the metals. It is malleable, may be hammered into very thin leaves, and may be drawn out into very fine wire, the thinnest silver-leaf having a thickness of only $\frac{1}{100000}$th of an inch, and one grain of the metal being capable of yielding 400 feet of wire. It possesses a high degree of tenacity, a wire with a diameter of $\frac{1}{12}$th of an inch being able to support a weight of nearly 188 pounds. It requires a heat of 1873° Fahr. to fuse it, and on cooling, expands at the moment of solidification. It is an excellent conductor of heat and electricity, and is not affected by exposure even to a moist atmosphere at any temperature. When, however, it is fused, it absorbs a considerable quantity of oxygen, which it expels in the act of solidification with a peculiar sound, technically known as *spitting*.* But although it does not rust or become oxidized, it usually becomes tarnished on prolonged exposure to the air, owing to the formation of a film of sulphide (or sulphuret) of silver, and this change occurs more rapidly in towns than in the country, in consequence of sulphuretted hydrogen being more abundant in the atmosphere of the former than of the latter. This metal is unaffected by the hydrates or nitrates of the alkalies, even at a high temperature, and hence silver crucibles, &c. are highly useful in many laboratory operations.

Hydrochloric and dilute sulphuric acid have scarcely any action on silver, but nitric acid and boiling sulphuric acid oxidize it, and form salts; nitric acid being by far its best solvent. Silver has strong affinities for chlorine, bromine, iodine, and sulphur, and combines with the first three and sulphuretted hydrogen at ordinary temperatures. It is well known that common salt, especially in the melted state, when left for any time in contact with silver, corrodes that metal, soda being formed from the oxygen of the air, while the liberated chlorine attacks the silver.

Silver is frequently met with in the native state, crystallized in cubes or octahedrons, or occurring in fibrous masses. It is also found in combination with gold, mercury, lead, antimony, arsenic, sulphur, &c., and sulphide of lead is almost always accompanied with a greater or less amount of sulphide of silver; it is, however, never found as an oxide.

Silver forms three compounds with oxygen—viz., a suboxide, Ag_2O; an oxide, AgO; and a peroxide, AgO_2. All these oxides possess the common properties of being reduced by heat to the metallic state, and of being very readily decomposed by the action of light. The oxide, AgO, is the only one of these compounds requiring special notice. It is a dark-brown heavy powder, devoid of taste or smell, somewhat soluble in water, to which it communicates a metallic taste and an alkaline reaction. It acts as a powerful base, neutralizing the strongest acids, and forming normal salts with them. It is obtained by the addition of a solution of potash to a solution of the nitrate or any other soluble salt of silver, falling as a hydrated oxide, which, at a temperature above 140°, becomes anhydrous. If a concentrated solution of ammonia be digested for some hours upon freshly precipitated oxide of silver, Fulminate of Silver (q. v.), or Fulminating Silver in the form of a black powder is produced, and the same dangerous compound is formed when an ammoniacal solution of nitrate or chloride of silver is precipitated by potash.

The salts which the oxide of silver forms with acids are characterized by the readiness with which they decompose, the mere action of light blackening and partially reducing them. None of these salts occur in nature. The following are the most important of those which have been formed artificially.

Nitrate of Silver (AgO,NO_5) crystallizes, in large colorless, transparent square tablets, which blacken on exposure to light, or in contact with organic matters, owing to reduction, and dissolve in their own weight of cold water. This property of producing a permanent black color with organic matters has led to its employment as a *marking ink** for linen, &c. The black stains which it forms on the skin, on linen, &c., may be removed by the employment of a strong solution of iodide of potassium, or more readily by a solution of cyanide of potassium. The crystals fuse at a temperature of about 425°, and the molten mass, when cast into cylindrical moulds, solidifies, and forms the sticks of *lunar caustic* which are employed in surgery, medicine and Photography (q. v.). Nitrate of silver is prepared by dissolving pure silver in moderately strong nitric acid, and evaporating till the solution is sufficiently concentrated to crystallize. 'The most characteristic test for the salts of silver is the action of hydrochloric acid, or of a soluble chloride, which produces a white curdy precipitate of chloride of silver, insoluble in nitric acid, but readily soluble in ammonia; it is also soluble in hyposulphite of soda, with which it forms an intensely sweet solution; cyanide of potassium also dissolves it; the chloride of silver speedily assumes a violet tinge when exposed to light.'—Miller's *Elements of Chemistry*, 2d ed., vol. ii. p. 732.

Of the haloid salts of silver, several occur native. The most important of these compounds is *chloride of silver* (AgCl), which is found native either in cubes or in a dense semi-transparent mass, and is known as *horn silver* and may be procured as a dense white flocculent precipitate by the procedure described in the preceding paragraph. In consequence of its sensibility to light, it is employed in photography. When heated to about 500°, it fuses into a yellow fluid, which, on cooling, solidifies into a yellowish gray semi-transparent horny mass. This salt is insoluble in water and in all the diluted acids, but dissolves in a solution of ammonia from which it crystallizes in octahedra. Its solution in a solution of hyposulphite of soda is employed in silvering iron, copper, and brass goods. Traces of this salt are found in seawater, the chloride of sodium probably acting as the solvent. *Bromide of silver* (AgBr) is found in Mexico, where it is known as *Plata verte*, or green silver, in the form of small crystals or crystalline, granules of a pale olive-green tint. *Iodide of silver* (AgI) occurs native in several Mexican mines in the form of thin, flexible, pearly scales.

Sulphide (or *sulphuret*) *of silver* (AgS) is the principal ore of silver. It occurs native, sometimes crystallized in cubes or octahedra, and sometimes in masses. From its gray metallic lustre, it has received from mineralogists the name of *silver glance*. It is

* Although ordinary air has no oxidizing action on silver, ozonized air rapidly attacks it.

* Brande gives the following directions for preparing marking ink: Dissolve two drachms of nitrate of silver and one drachm of gum-arabic in seven drachms of water, and color the liquid with Indian ink. The cloth must be first prepared by moistening the spot with a few drops of a soda solution, prepared by dissolving two ounces of crystallized carbonate of soda and two drachms of gum in four ounces of water. Professor Miller recommends, as a cheap indelible marking ink, a solution of coal tar in naphtha; it resists the action of chlorine, and is used by bleachers to mark their goods.

well known that if silver spoons are allowed to remain in contact with boiled eggs for some time, they become tarnished by the action of the sulphur; a minute quantity of sulphuretted hydrogen being probably evolved. The discoloration is easily removed by washing the darkened silver with a solution of cyanide of potassium. Sulphide of silver unites with various other metallic sulphides when fused with them, especially with the sulphides of arsenic and antimony. *Red silver ore* ($3AgS,SbS_3$) is a native compound of this kind.

The alloys of silver and copper (see ALLOY and MINT), when cast into ingots, are usually found to differ in their composition in the internal and external parts, in consequence of a molecular change that takes place during the cooling and slow solidification of the molten mass. In bars containing more than 719 parts of silver in 1000, the central portions are richer in silver than the exterior; in alloys of less value, the reverse is observed, while in ingots containing 950 or more parts of silver in 1000, the composition is nearly uniform throughout. When exactly 719 parts of silver and 281 of copper are combined (corresponding to the formula Ag_2Cu_1), no separation whatever of the metals occurs. Many metals, as tin, zinc, antimony, bismuth, arsenic, &c., when mixed with silver, render it brittle and unfit for its ordinary uses; they are, however, easily removed in the process of refining. An alloy consisting of five parts of silver, six of brass, and two of zinc, is used as a solder for silver. An alloy of silver and mercury, known as *silver amalgam*, occurs native in a crystallized form. It is a mineral of a silvery white color, and its composition is represented by the formula $AgHg_2$.

Silver, like gold, has been known and prized from the earliest ages. The silver mines of Mexico were, until quite recently, by far the richest known to exist. Their estimated annual yield is about 1,600,000 lbs. troy of the pure metal. Until the remarkable discoveries of silver ore in Nevada and adjoining states in 1859 and 1860, Chili and Peru had long stood next to Mexico in their yield, each furnishing about one-sixth of the produce of that country. Bolivia is also rich in silver; but the recent extraordinary development of silver mining in the western regions of the United States, appears to have raised their produce to at least a par with that of Mexico, so that these two countries now furnish three-fourths of all the silver obtained in the world.

Of European countries, Spain is the most productive, the richest mines being those of Hiendelaencina, in the province of Guadalaxara, which were first extensively opened in 1846. These have yielded immense wealth, but their produce has much declined since 1858. Silver glance is the principal ore, although several others are found, including quantities of the formerly rare mineral freieslebenite, which contains about 23 per cent. of silver. Next to Spain, Austria, Saxony, and the Harz district in Northern Germany, yield the largest supplies. The silver mines of Kongsberg in Norway are likewise valuable, and have been long famous. Great Britain has no silver mines, properly so called, but since the introduction in 1829 of Pattinson's process for the desilverizing of lead smelted from argentiferous galena, a large quantity has been annually produced in this way. The highest yield of silver by this process was in 1868, and amounted to 841,328 ounces, but owing to the gradual decline since then in the produce of British lead, the silver obtained from it had fallen in 1880 to 295,518 ounces (see LEAD).—In the mineral veins of Cornwall, some 'bunches' of true silver ores have occasionaly been found, but of limited extent.

The forms in which silver is found in nature are numerous, but we need only notice a few of them. It is frequently found native in crystallized and amorphous masses, which are sometimes of considerable size. One fine piece found at Kongsberg is now in the Copenhagen Museum, and weighs 500 lbs. But the quantity of silver found in nature in the metallic state is comparatively small. Its principal ores are the different sulphides or sulphurets —viz., silver glance, or sulphuret of silver, containing when pure 87 parts of silver and 13 of sulphur; brittle silver ore, or sulphuret of silver and antimony, of which the composition is, silver 68·5, antimony 14·7, and sulphur 16·4; and red silver ore, called also ruby silver, of which there is a dark and a light kind, the composition of the former being similar to brittle silver ore, but it is a little less rich in silver, and the latter only differs in containing arsenic instead of antimony. The bulk of the silver obtained in Mexico and South America is got from these ores. The only other of much importance, except the mixed ores to be presently noticed, is horn silver, or chloride of silver. In a pure state, it consists of silver 75, and chlorine 25. It occurs extensively in Mexico and Peru, but is not common in European mines.

Besides the ores named above, a good deal of the silver of commerce is obtained from mixed ores, that is, the ores of other metals are frequently found to contain it. In many cases, the amount of silver falls greatly short of 1 per cent. These ores are for the most part sulphurets of lead, arsenic, copper, zinc, and iron.

In the reduction of silver ores, the processes followed are based upon the fact, that both lead and mercury have a strong affinity for silver. A more recent process depends upon the solubility of chloride of silver in a hot solution of common salt, and its separation again on cooling.

The simplest process is ordinary smelting, and is only applied to the richest ores. These are crushed, mixed with old slag, lead in some form, and a little iron ore and lime. The mixture is then heated in a furnace with charcoal, which brings down the silver

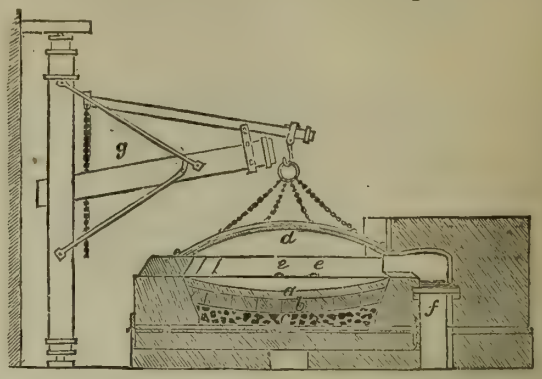


Fig. 1.—Silver Cupellation Furnace.
a, sole formed of wood ashes; *b*, bricks; *c*, bed of slag; *d*, dome of iron plate; *ee*, tuyères for bellows; *f*, fireplace; *g*, crane for lifting dome.

and lead together as an alloy. The silver is afterwards easily separated by cupellation, the principle of which is described in the article ASSAY; but on the large scale, instead of a small bone ash cupel, a cupellation furnace, say 6 feet in diameter, is used, of which fig. 1 is a section. Here the alloy is melted, bellows are used to remove the lead as litharge, or oxide of lead, and a cake of silver is left on the cupel forming the bottom of the furnace.

It happens that not many even of the richer ores are pure enough to be treated with advantage by simply roasting them with lead; accordingly, another plan, called the amalgamation process, is more commonly adopted. The following is an outline of the way in which this is practised at Freiberg in Saxony. The vein

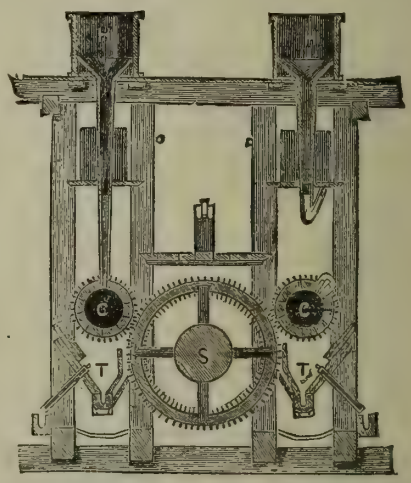

Fig. 2.—Vertical Section of Amalgamating Apparatus.
CC, oak barrels; S, toothed wheel for setting barrels in motion; H, hoppers with hose for passing the mixed ore into the barrels; TT, troughs for the reception of the charge when the amalgamation is complete.

stuff (largely silica) containing a mixed ore of lead, copper, zinc, &c. as sulphurets, and only from 3 to 3½ oz. of silver per cwt., is ground to powder, as described under METALLURGY; but some sulphuret of iron is also present, or must be added. About 10 per cent. of common salt is then mixed with the ore, and the mixture heated in a Reverberatory Furnace (q. v.) to a temperature sufficient to expel water, and in part arsenic, zinc, and antimony. After two hours, the sulphur of the sulphurets takes fire, and is burned off as sulphurous acid, or converted into sulphuric acid, so that the metals become oxides and sulphates. The temperature of the furnace is now raised, when the chlorine of the common salt forms volatile chlorides with zinc, antimony, and iron, and a fixed chloride with silver. During the roasting, the contents of the furnace are continually stirred, so that they ultimately form a coarse powder.

The product of the roasting furnace, after being ground to a fine powder, is mixed in the proportion of 10 cwt. with 3 cwt. of water and 1 cwt. of iron in fragments; the mixture being effected

in oak casks, which are then made to revolve for two hours on their axes. See figs. 2 and 3. During the operation the iron decomposes the metallic chlorides in the roasted ore, forming chloride of iron, while the copper is partly reduced to sub-chloride and partly to metallic copper. If there is not enough iron

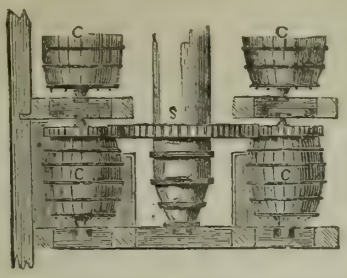

Fig. 3.—Plan of Part of Amalgamating Apparatus.

present to convert the copper into sub-chloride, then mercury will be wasted in the next stage by conversion into its sub-chloride. Quicksilver to the amount of 5 cwt. is next run into each of the casks, which are then set in motion, and continue for 22 hours at the rate of 12 revolutions per minute. The result of this is, that the silver being precipitated by the presence of metallic copper, is then dissolved by the mercury, but the amalgam so formed is usually a complex one.

In order to separate the amalgam from the earthy matters and the sulphates and chlorides, the barrels, which were hitherto only two-thirds full, are now filled with water (the dilution throwing down any chloride of silver held in solution by the sea-salt), and kept revolving for two hours; after which, by means of a stop-cock, the amalgam is allowed to flow into the amalgam chamber, and the rest of the contents, except the iron fragments, into a washtun.

The superfluous quicksilver has next to be separated from the amalgam. This is done in bags of ticking through which the mercury at first flows readily by its own weight, and is afterwards squeezed out on a flat surface. The result of this operation is, that the amalgam of mercury, silver, copper, &c., is left in the bags: its actual composition being nearly 85 per cent. of mer-

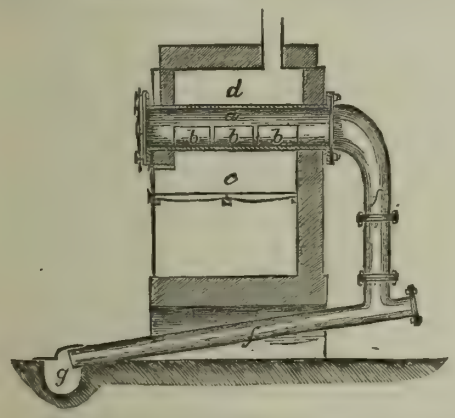

Fig. 4.—Furnace for Distilling the Amalgam.
a, iron retort; *b*, iron pots; *c*, fireplace; *d*, flue; *f*, condensing pipe; *g*, trough for collecting mercury.

cury, 10 per cent. of silver, and 5 of copper, lead, and antimony. Finally, the quicksilver of the amalgam itself is separated by heat in the distilling furnace, fig. 4. Here the amalgam is put into a row of iron pots, which go into a large retort. When heat is applied, the quicksilver volatilizes, and is condensed in a pipe attached to the retort, from which it is collected in a trough. The impure silver left in the retort is refined by fusion and subsequent cupellation.

There is another process carried on at Freiberg and elsewhere, by which the use of mercury is dispensed with. It consists in treating the ore as above described till it leaves the roasting furnace. At this stage, the roasted ore is digested in a warm concentrated solution of sea-salt, which readily dissolves the chloride of silver. The solution is then passed through wooden tubs containing metallic copper, which has the property of decomposing the chloride of silver: the chlorine unites with the copper to form chloride of copper, and the silver is precipitated.

[This process is now for the most part abandoned, and at Freiberg an argentiferous copper matt obtained in smelting mixed ores is treated with sulphuric acid, by which sulphate of copper is formed, and the silver recovered from the residue.]

In Mexico, where indeed the process was first introduced, the extraction of the silver from its ores is chiefly accomplished by amalgamation, but the plan employed differs a good deal in its details from the Saxon method described above. Of late years, the sodium-amalgam process of Mr. Crookes has been used with advantage for the extraction of silver in several American mining districts (see SODIUM-AMALGAM).

It has now become a common practice at Swansea, where the great British copper-smelting works are situated, to extract the silver which exists in an appreciable, though small quantity, in many copper ores. By one process, copper smelted from an argentiferous ore is melted with three or four times its weight of lead, and cast into ingots. When these are moderately heated, the copper does not fuse, but the lead and silver melt, and run off together, and the silver is then separated by cupellation. From the burnt pyrites of vitriol works, so recently a waste product, not only is the iron and copper, but the silver, which exists in exceedingly small proportion, is now recovered by the use of iodide of potassium.

The physical and chemical properties of silver are such as make it specially valuable for many purposes in the arts; the chief of which are noticed in the articles ALLOY, MINT, PLATING, GALVANISM, and PHOTOGRAPHY. Ordinary mirrors have their *silvering* produced by a coating of an amalgam of tin and mercury; but for some years, mirrors coated by a patent process with real silver, and backed by a layer of some composition, which protects it from the blackening action of sulphuretted hydrogen, have been made in great numbers.

MEDICINAL USES OF SILVER. *Nitrate of silver*, in small doses, constitutes an excellent tonic, and it appears to exert almost a specific influence over certain convulsive diseases. As a tonic, it is frequently prescribed in the early stages of phthisis, and in cases of irritability of the mucous membrane of the stomach; and epilepsy and chorea frequently yield to its influence, when many other remedies have been tried in vain. There is unfortunately one great drawback to its administration—viz., that when its use has been continued for some time, this salt communicates a permanent slate-like or bluish-gray hue to the skin. There is very little danger of this change of color occurring, if the medicine is not administered for a longer period than three months. In prescribing this salt, it is usual to begin with a small dose, about one-sixth of a grain, and gradually to increase it to two or three grains, three times a day. It is best administered in pills made with some vegetable extract. The surgical uses of nitrate of silver have been already noticed in the article on LUNAR CAUSTIC.

Oxide of silver is employed in the same cases as the nitrate. It is especially recommended in chronic affections of the stomach, and in menorrhagia. It may be given in the same doses as nitrate. *Chloride of silver* has been employed both in America and in Germany in the same cases as the nitrate, and in certain forms of syphilitic disease.

PRICE OF SILVER. The value of silver has recently undergone a remarkable depreciation, causing grave commercial inconvenience and loss, especially where silver is the standard, as in India. The average price for the ounce of standard silver in 1870 was 60¼d; in 1878 only 50$\frac{1}{16}$d. A chief cause of depreciation is the great recent production. The change in value has promoted the controversy on 'bimetallism;' and in 1879 the United States 'monetized' silver, or made it equally a legal tender with gold, though it was then 11 per cent. less valuable in the market.

SILVERING GLASS. See MIRROR.

SIMANCAS, a village of 900 inhabitants, 7 miles S.W. of Valladolid. S. is famous as the place where the national archives of Spain are kept. They were removed hither by Cardinal Ximenes.

SIMARUBA'CEÆ, a natural order of exogenous plants, consisting of trees and shrubs; with alternate, generally compound leaves, without stipules; regular, generally hermaphrodite flowers. The species are not numerous; they are found in the tropical parts of Asia, Africa, and America. The whole order is characterized by great bitterness, and several of the species are used as tonics in dysentery, &c. Quassia (q. v.) and Bitterwood (q. v.) belong to it.

SIMBI'RSK, a government of Russia, bounded on the E. by the Volga, and on the W. by the governments of Nijni-Novgorod and Penza. Area, 19,050 sq. m.; pop. (1880) 1,410,000. The surface is for the most part level, and the soil of remarkable fertility, and there are excellent and extensive meadows and pasture-grounds. The fisheries and the commerce on the Volga, and cattle-breeding, are important.

SIMBIRSK, a capital of the Russian government of the same name, on the right bank of the Volga, 220 miles south-east of Nijni-Novgorod. Leather, soap, and candles are manufactured, considerable trade is carried on by the Volga, and there is a famous annual fair. During the years 1864 and 1865, S. suffered severely from fires. Pop. (1880) 26,900.

SIMEON, Rev. Charles, an eminent evangelical preacher of the English Church, was born at Reading in Berkshire, September 24, 1758. Educated at Eton and Cambridge, he was ordained a priest in 1782. His first religious impressions occurred during his residence at the university, and produced a permanent change in his character. From being a somewhat vain and dressy young gentleman, he passed into an ardent and zealous preacher of the Cross, and this he remained during the fifty-four years of his public ministry. His career was not marked by many incidents. Appointed vicar of Trinity Church, Cambridge, in the year of his ordination, and vice-provost of his own college (King's) in 1790, he continued to hold these offices to the close of his life, November 13, 1836. As a preacher S. was distinguished for an impassioned evangelicalism in language, sentiment, and doctrine, that at first roused against him a bitter and protracted opposition. His earnestness, however, met with its due reward. Friends and followers sprung up; and in course of time S. became a center of evangelical influence, that began to spread itself over the whole church, and gave birth to its great missionary activity in recent years. S. may even be regarded as the founder of the 'Low-church' party, and on the whole, fairly represents their earnestness, dogmatism, mediocre intellect, and limited scholarship. For an account of S.'s life and labors, see *Memoirs of the Rev. Charles Simeon*, by the Rev. W. Carus (Lond. 1857). S.'s *Horæ Homileticæ* (21 vols., 1832) are very popular among sermon-readers and sermon-makers of evangelical tendencies.

SI'MEON STYLI'TÉS. See Pillar-saints.

SIMFERO'POL, a town of Russia, in the Crimea, capital of the government of Taurida, stands on the Salghir, 45 miles north-east of Sebastapol. The valley of the river is studded with charming villas, and the town is surrounded by gardens, and has a picturesque appearance. The older part comprises the old Tartar town of Ak-Metchet, or White Mosque—the new part, containing the government buildings, is very handsome. Fruits are largely grown in the vicinity, and exported. Pop. (1880) 52,800.

SI'MIA and SIMI'ADÆ. See Monkey.

SIMILAR FIGURES, in Geometry, are figures which exactly correspond in shape, but may or may not be of the same size. If the figures be rectilineal, then the criterion of similarity is that every pair of corresponding sides should have the same ratio to each other, and that each angle of the one figure should be equal to a corresponding angle of the other. If the figures be triangular, the proportionality of the sides carries with it the equality of the angles, and *vice versâ*, but only in this case. *Similar segments* of circles are those in which, and on whose bases, similar triangles can be inscribed; or, as it is otherwise expressed, those which contain equal angles—a satisfactory test that they are each the same part of their respective circles. *Similar solids* are those which are bounded by similar planes similarly situated to each other. All similar plane figures are to one another as the squares of any corresponding sides, and all similar solids are as the cubes of their corresponding sides. Thus, a circle which has 3 (3 : 1) times the diameter of another, has 9 ($3^2 : 1^2$) times its area, and a globe which has 3 (3 : 1) times the diameter of another has 27 ($3^3 : 1^3$) times the volume.

SI'MLA, a British sanatorium, in the north-west of India, about 170 miles in direct line north of Delhi. It consists of a number of houses irregularly scattered over a mountain-ridge, with a noble panorama expanding on all sides of it. European fruits and vegetables are successfully cultivated, and the climate is salubrious. The pop., which is very fluctuating, was given in 1871 at 7037.

SIMMS, William Gilmore, American author, was born at Charleston, South Carolina, April 17, 1806, of Irish extraction. He made verses at the age of seven; and during the war of 1812, celebrated in rhyme the exploits of the American army and navy. Left in charge of his grandmother at Charleston, he was placed with a druggist; but at 18 began the study of law; was admitted to the bar at 22; published *Early Lays* and *Lyrical and other Poems* (1827); and became (1828) editor of *The City Gazette*, and published *The Vision of Cortes, Cain, and other Poems* (1829), and *The Tri-Color*, a poetical glorification of the French revolution (1830). In 1832, his paper, opposing nullification, failed; and he lost his wife, father, and grandmother, and took refuge in New England, where, at Hingham, Massachusetts, he wrote his best poem, *Atalantis, a Story of the Sea* (1833); and the same year, *Martin Faber*, the story of a criminal. From this time, he poured out rather than wrote poems, novels, histories, and biographies in rapid succession, which may best be classed in groups. Of poems, he published *Southern Passages and Pictures* (1839); *Donna Anna* (1843); *Grouped Thoughts and Scattered Fancies* (1845); *Lays of the Palmetto*—ballads of Southern heroism in the war with Mexico (1848); *Poems Descriptive, Dramatic, and Legendary* (1854); *Areytos, or Songs and Ballads of the South* (1860). Of dramas—*Norman Maurin, or the Man of the People*; *Michael Bonham, or the Fall of the Alamo*; and a stage adaptation of *Timon of Athens*. Of prose romances of the imagination—*The Book of My Lady* (1833); *Carl Werner* (1838); *Confession, or the Blind Heart* (1842); *Castle Dismal* (1845); *The Wigwam and the Cabin*, two series (1845, 1846); *Marie de Bernière* (1853).

Of historical romances—*The Yemassee* (1835); *Pelayo* (1838); *Count Julien* (1845); *The Damsel of Darien* (1845); *The Lily and the Totem, or the Huguenots in Florida* (1845); *The Maroon and other Tales* (1855); *Vasconcelos* (1857); *Cassique of Kiawah* (1860). Of revolutionary stories—*The Partisan* (1835); *Mellichamp* (1851); *Katherine Walton* (1851); *The Scout* (1841); *The Kinsman, or the Black Riders of the Congaree* (1841); *Woodcraft* (1855); *The Foragers* (1855); *Eutaw* (1856); these five being stories of the war in the Carolinas. Of local tales—*Guy Rivers* (1834); *Richard Hurdis* (1838); *Border Beagles* (1840); *Beauchamps* (1842); *Helen Halsey* (1845); *The Golden Christmas* (1852); *Charlemont* (1856). His other works comprise a History of South Carolina; South Carolina in the Revolution; Lives of General Marion, Captain John Smith, Chevalier Bayard, General Greene; Civil War in the South; American Loyalists of the Revolution; Views and Reviews of American Literature; The Morals of Slavery, &c. Residing in South Carolina during the War of Secession, he sustained the Southern cause in a weekly newspaper, and had his house and library wrecked by Federal soldiers. Of his various and voluminous works, some are of high excellence. He died in 1870.

SIMO'DA (Lowland), a harbor of Japan, at the southern extremity of Cape Idzu, and about 80 miles from Yeddo, opened to foreign commerce by the Americans in 1854. In 1854, the town was nearly destroyed by an earthquake, while the harbor was so scoured out that hardly any holding-ground was left for ships on the granite bottom. The population was formerly estimated at 80,000, but is now reckoned at about 4000.

SIMON, Richard, a distinguished orientalist and critical scholar, was born at Dieppe, May 13, 1638. Having completed his studies, he entered the Congregation of the Oratory in 1659, but soon afterwards withdrew. He returned, however, in the latter part of 1662. For a time, he delivered lectures on Philosophy in the college of Juilly; but his studies eventually turned upon theology, oriental languages, and biblical criticism. At one time, he thought of entering the Jesuit order, but he remained in the Oratory; and it was while still a member of that congregation that he published his well-known work on the doctrine of the oriental church regarding the Eucharist, designed as a supplement to the celebrated *Defence of the Perpetuity of the Faith in the Blessed Eucharist*, by Arnauld and Nicole, but criticising that work very severely. This and other controversies to which his later writings gave rise, led to his again withdrawing from the Oratory in 1678. In that year he retired to Belleville, as cure; but in 1682, he resigned his parish, and lived in literary retirement, first at Dieppe, and afterwards in Paris. His health having given way, he returned once again to his native place Dieppe, where he died in April 1712. Few writers of his age played so prominent a part in the world of letters, and especially in its polemics. There is hardly a critical or theological scholar among his contemporaries with whom he did not break a lance—Spanheim, Le Clerc, Du Pin, Jurieu, and Jurieu's great antagonist, Bossuet. The principal work of S. is his *Histoire Critique du Vieux Testament* (Paris, 1678), in which he anticipates the most important conclusions of all the later rationalistic scholars of Germany, and also their method of investigation. For example, he conceives himself to have disproved the Mosaic authorship of the Pentateuch, and assigns its composition to the scribes of the time of Ezra.

Other writings of S.'s are *Histoire Critique du Texte du Nouveau Testament* (Rotterd. 1689); *Disquisitiones Criticæ de variis Bibliorum Editionibus* (1684); *De l'Inspiration des Livres Sacrés* (Rotterd. 1687); and *L'Histoire Critique des Principeaux Commentateurs du Nouveau Testament* (Rotterd. 1692), in which he assails the theology of the Fathers, and particularly that of Augustine, as a departure from the simple and less rigid doctrines of the primitive church. Among the fathers, his most esteemed authority was Chrysostom. Bossuet replied to this last work by his *Defense de la Tradition et des Saints Pères*. S. frequently published under assumed names—as his *Dissertation Critique* on Dupin's *Library of Ecclesiastical Writers*, under the name of Jean Reuchlin; a work, *Histoire Critique sur la Créance et des Coutumes des Nations du Levant*, under the anagram of Monis; and a *Histoire de l'Origine et du Progrès des Revenus Ecclésiastiques* under the name of Jerome Acosta. No collected edition of his works has ever appeared; in the natural progress of the science of criticism, the most famous of them have lost most of their prestige, and are displaced by recent, and often second-hand compilations upon the subjects, which, in the days of S., were comparatively new and unexplored; but still there is much to be learned even from such of his works as have been forgotten by ordinary students.

SIMO'NIDES, a celebrated Greek lyric poet, was born at Iulis, in the island of Ceos, in the year 556 B.C., and educated probably with a view to making music and poetry a profession. He left his native island on the invitation of Hipparchus, who, by means of great rewards, induced him to reside at Athens, where also lived at that time Anacreon and Lasus, the teacher of Pindar, although no intimacy seems to have sprung up between S. and his two rivals. It was probably after the expulsion of Hippias (510 B.C.) that he took up his residence in Thessaly, under the patronage of the Aleuads and Scopads, who appear to have treated him in a very niggardly fashion. Shortly before the invasion of Greece by the Persians, he returned to Athens, and employed his poetic powers in the composition of elegies, epigrams, dirges, &c., in connection with that momentous struggle, taking the prize, in regard to the battle of Marathon, out of the hands of his rival Æschylus. In the year 477 B.C., when S. was 80 years of age, he came off victor for the 56th time in a poetical contest at Athens. Shortly after this, he went to reside at the court of Hiero of Syracuse, where he died in 467 B.C., at the age of 90. S. appears to have scandalized his contemporaries by writing for hire; and Pindar, his great rival, accuses him, apparently not without good reason, of excessive avarice. His poetry is imbued with a comparatively high morality. He brought to perfection the elegy and epigram, and excelled in the dithyramb and triumphal ode; he seems also to have completed the Greek alphabet by the addition of the double letters and long vowels, and to have invented the art of artificial memory.. The characteristics of his poetry are sweetness, polish combined with simplicity, genuine pathos, and great power of expression, although in originality he is much inferior to his contemporary Pindar. The best edition of his fragments is that of Schneidewin, entitled *Simonidis Cei Carminum Reliquiæ* (Brunswick, 1835).

This S. must be carefully distinguished from the iambic poet SIMONIDES of Amorgos, who flourished about 100 years previous to S. of Ceos.

SIMONOSE'KI, a town of Japan, in 33° 56′ N. lat., and 131° E. long., at the south-west extremity of the island of Nipon, and at the entrance of the inland sea Suonada. It is surrounded by hills, and consists of one main street, containing about 20,000 inhabitants. The warehouses—the principal buildings—are built of mud and wood, coated with cement, and are said to be fireproof. S. is a depôt for receiving the European Imports from Nagasaki, to be sent into the interior of the country; also for the produce from Osaca, which is reshipped to Nagasaki and other places.

SI'MONY, in English Law, is the corrupt presentation of any one to an ecclesiastical benefice for gift-money or reward, and is so called from its resemblance to the sin of Simon Magus. In the canon law, it was considered a heinous crime, and a kind of heresy. As the canonical punishment, however, was not deemed sufficient, a statute was passed in the time of Elizabeth, defining its punishment. A simoniacal presentation was declared to be utterly void, and the person giving or taking the gift or reward forfeited double the value of one year's profit; and the person accepting the benefice was disabled from ever holding the same benefice. Presentation bonds, however, taken by a patron from a presentee to resign the benefice at a future period in favor of some one to be named by the patron, are not illegal, provided the nominee is either by blood or marriage an uncle, son, grandson, brother, nephew, or grandnephew of the patron, and provided the bond is registered for public inspection in the diocese. The result of the statutes is that it is not simony for a layman or spiritual person, not purchasing for himself, to purchase while the church is full, either an advowson or next presentation, however immediate may be the prospect of a vacancy, unless that vacancy is to be occasioned by some agreement or arrangement between the parties. Nor is it simony for a spiritual person to purchase for himself an advowson, although under similar circumstances. It is, however, simony for any person to purchase the next presentation while the church is vacant; and it is simony for a spiritual person to purchase for himself the next presentation, although the church be full.

SIMOO'M (otherwise written Simoun, Semoun, Samoun Samûn), or Sambuli, a name derived from the Arabic *samma*, signifying hot, poisonous, or generally whatever is disagreeable or dangerous, and applied to the hot suffocating winds which are peculiar to the hot sandy deserts of Africa and Western Asia. In Egypt, it is called *khamsin*, (Ar., fifty) because it generally continues to blow for 50 days, from the end of April to the time of the inundation of the Nile.

Owing to the great power of the sun's rays, the extreme dryness of the air, and the small conducting power of sand causing the accumulation of heat on the surface, the superficial layers of sand in the deserts of Africa and Arabia often become heated to 200° F. to a depth of several inches. The air resting on this hot sand becomes also highly heated, thus giving rise to ascending currents; air consequently flows towards these heated places from all sides, and these different currents meeting, cyclones or whirling masses of air are formed, which are swept onward by the wind prevailing at the time. Since the temperature, originally high, is still further raised by the heated grains of sand with which the air is loaded, it rapidly increases to a degree almost intolerable. In the shade, it was observed by Burckhardt in 1813 to have risen to 122°; and by the British Embassy to Abyssinia in 1841 to 126°. It is to the parching dryness of this wind, its glowing heat (about 200°), and its choking dust, and not to any poisonous qualities it possesses, that its destructive effects on animal life are to be ascribed.

The approach of the Simoom is first indicated by a thin haze along the horizon, which rapidly becomes denser, and quickly overspreads the whole sky. Fierce gusts of wind follow accompanied with clouds of red and burning sand, which often present the appearance of huge columns of dust whirling forward; and vast mounds of sand are transported from place to place by the terrible energy of the tempest. By these mounds of sand, large caravans are frequently destroyed; and even great armies have been overwhelmed by them, as in the case of Cambyses, who was overtaken by the Simoom on his march through the desert to pillage the temple of Jupiter Ammon, and perished with 50,000 of his troops. The destruction of Sennacherib's army is supposed to have been caused by the Simoom. The Simoom generally lasts from 6 to 12 hours, but sometimes for a longer period.

The effects of this wind are felt in neighboring regions, where it is known under different names, and it is subject to important modifications by the nature of the earth's surface over which it passes. In Italy, it is called the *Sirocco*, which blows occasionally over Sicily, South Italy, and adjoining districts. It is a hot moist wind, receiving its heat from the Sahara, and acquiring its moisture in its passage northward over the Mediterranean. It is the plague of Sicily and Naples, and while it lasts a haze obscures the atmosphere, and such is the fatigue which it occasions that the streets of Palermo become quite deserted. The Sirocco sometimes extends to the shores of the Black and Caspian Seas, and under its blighting touch, sheep and cattle die in the steppes beyond the Volga, and vegetation is withered and dried up. It is called the *Samiel* in Turkey, from its reputed poisonous qualities. The *Solano* of Spain is a south-east wind, extremely hot and loaded with fine dust, which prevails at certain seasons in the plains of Mancha and Andalusia, particularly at Seville and Cadiz. It produces giddiness, and heats the blood to an unusual degree, causing general uneasiness and irritation; hence, the Spanish proverb: 'Ask no favor during the Solano.' The Harmattan (q. v.) of Guinea and Senegambia belongs to the same class of winds.

SIMPLE CONTRACT, in English law, means any contract which is constituted by word of mouth or by a writing not under seal. See CONTRACT.

SI'MPLON (Ital. *Sempione*), a famous mountain of Switzerland, one of the Lepontine Alps, in the east of the canton of Valais, and near the Piedmontese frontier, rises to the height of 11,124 feet. The *Simplon Road*, one of the greatest engineering achievements of modern times, leads over a shoulder of the mountain from which it derives its name (the *Pass of the Simplon*, 6592 feet) from Brieg in Valais to Domo d'Ossola in the north of Piedmont. The road was commenced in 1800 under the direction of Napoleon, and was completed in 1806. It is from 25 to 30 feet broad, and has nowhere a slope greater than 1 in 13. It is carried across 611 bridges, over numerous galleries cut out of the natural rock, or built of solid masonry, and through great tunnels. Close to the highest point is the *New Hospice*, one of the 20 edifices on this route for the shelter of travelers.

SIMPSON, SIR JAMES YOUNG, was born at Bathgate, Linlithgowshire, in 1811. He early showed a peculiar talent for medical observation and research; and in the prosecution of his professional studies at the University of Edinburgh, so attracted the notice of his teachers as to inspire all of them with an active interest in his future career. He graduated as doctor in medicine in 1832, on which occasion his inaugural thesis won the highest admiration. Professor Thomson chose him as his professional assistant, and employed him in the preparation of his course of lectures on General Pathology. During the illness of the professor, Mr. S. supplied his place in the lecture-room with unusual skill and address.

He now began professional practice on his own account; and in 1840, succeeded Professor Hamilton as Professor of Midwifery in the University of Edinburgh. This position he has held with yearly enhanced distinction, and by the rigidly scientific, while popularly attractive, character of his prelections, has contributed greatly to the renown of the Edinburgh school, both at home and abroad. He was indefatigable, amid the distracting cares of an extensive practice, in promoting the scientific perfection of his art; and his two volumes of Obstetric Memoirs, edited by Drs. Priestly and Storrer, contain the fruits of much patient and ingenious research. The discovery by which he will be more par-

ticularly remembered, however, is that of the anæsthetic virtues of chloroform. The so-called sulphuric ether had been employed in America by Morton to produce anæsthesia during labor; but to S. belongs the credit of having, in 1847, first introduced to the scientific world the far safer, more certain, and now universally adopted agent of chloroform. Another innovation which surgical practice owes to Professor S. is the stoppage of hæmorrhage by Acupressure (q. v.). In his own peculiar field of obstetrics, his improvements on the old methods of practice are numerous and valuable; while his contributions to antiquarian research would of themselves create an independent reputation in that field. Besides the Obstetric Memoirs already mentioned, he published a volume on Acupressure; and many papers and notices read before the Royal and Antiquarian Societies of Edinburgh. Among these may be enumerated: Antiquarian Notices of Leprosy; On the Contagiousness of Cholera; Ancient Roman Medicine Stamps; Was the Roman Army provided with Medical Officers? On Syphilis in Scotland, &c. His scientific services were recognized by innumerable medical associations; while his professional distinction secured for him a baronetcy in 1866. He died on the 6th of May 1870. A statue of S. was erected in Edinburgh in 1877. See the Memoir by Duns (1873).

SIMROCK, KARL, a German poet and scholar, who has done more perhaps than any other man to make his countrymen familiar with their early literature, was born at Bonn, 28th August 1802. He studied at the university of his native city and afterwards at Berlin, and in 1823 entered the Prussian state service. His first work was a translation into Modern German of the *Nibelungenlied* (Berl. 1827; 9th. ed. Stuttg. and Tüb. 1854), followed by a translation of the songs admitted by Lachmann to be genuine, under the title *Zwanzig Lieder von den Nibelungen* (Bonn. 1840). Soon after the publication of his translation of Hartmann von der Aue's *Armer Heinrich* (Berl. 1830), he was compelled to leave the Prussian service on account of a revolutionary poem which he wrote. Afterwards he devoted himself exclusively to literature, and more particularly to the early literature of his own country, which he has modernized in splendid style. In 1850, he was appointed professor of German Language and Literature at Bonn, a situation which he held till his death, which occurred in July 1876. His principal works besides those already mentioned, are:

Quellen des Shakspeare in Novellen, Märchen, und Sagen ('Sources of Shakspeare in Novels, Tales, and Legends,' 3 vols. Berl. 1831), executed in conjunction with Echtermeyer and Henschel, but of which the most important part was S.'s; *Novellenschatz der Italiener* (Berl. 1832); a translation, with commentary, of the poems of Walther von der Vogelweide (2 vols. Berl. 1833), in conjunction with Wackernagel; and of *Wieland der Schmied. Deutsch Heldensage* (Bonn. 1835), one of the freshest of the German medieval epics; *Rheinsagen aus dem Munde des Volkes und Deutscher Dichter, fur Schule, Haus, und Wanderschaft* ('Legends of the Rhine, from the mouth of the people and German poets, for School, Home, and Travelling,' 4th ed. Bonn. 1850; latest ed. 1857); a collection of German *Volksbücher* ('People's Books'), comprising national proverbs, songs, and riddles, besides a vast quantity of stories (these, carried on for several years, include many vols.); a translation of Wolfram von Eschenbach's *Parzival und Titurel* (Stuttg. and Tüb. 1842); and *Das Heldenbuch*, partly translations and partly original poems (1843—1849), illustrative of the heroic traditions of the Teutonic race. A separate collection of his own poems (*Gedichte*) was published at Leipzig (1844, new ed. 1863). Later productions are a translation of the Songs of the Edda (Stuttg. and Tüb. 1851, 3d ed. 1863); a *Handbuch der Deutschen Mythologie* (2 vols. Bonn. 1853—1855, 2d ed. 1864); an *Altdeutsches Lesebuch in Neudeutscher Sprache* (Stuttg. and Tüb. 1854; *Das Deutsche Kinderbuch, Reime, Lieder &c.* (1856—1857); *Der Wartburg-Krieg, herausgegeben, geordnet, ubersetzt, und erläutert* (1858); *Die Nibelungenstrophe und ihr Ursprung; Beitrag zur Deutschen Metrik* (1858); *Lieder vom Deutschen Vaterlande* (1863); *Deutsche Märchen* (1864); *Gedichte Shakspeare's* (1867).

SIMSON, ROBERT, a celebrated Scotch mathematician, was born at Kirkton Hall in Ayrshire, October 1687. He was educated at the university of Glasgow with a view to the clerical profession, and attained great eminence in classical and mathematical knowledge. His taste for mathematics gradually gained the ascendency, and all other pursuits were abandoned. After a brief residence in London, during which he made the acquaintance of Dr. Halley, Mr. Ditton, and others, he returned to Glasgow, where in 1711 he was appointed Professor of Mathematics, and for 50 years discharged his professorial duties. S.'s reputation rests chiefly on his 'restorations,' or, as they might more properly be called, 'reconstructions,' of the Greek geometers. Some good judges are of opinion that he has corrected many errors in the original text, though his respect for the Greek mathematicians always led him to refer these to the ignorance of editors, and the negligence of copyists. His first attempt in this direction was to discover the signification of Euclid's porisms, the only datum being a most obscure and tantalizing description of them by Pappus, the indefiniteness of which had foiled both Fermat and Halley. In this difficult task, S., however, succeeded; and a similar attempt, attended with similar success, on the 'loci plani' and the 'sectio determinata' of Apollonius, stamped him as one of the most elegant geometers of modern times. With the thorough insight which he had thus obtained into the nature and processes of the Greek analysis, he set himself to the correction of Euclid's *Elements*. This last work was published in 1758, and has deservedly enjoyed a high character; it has been frequently re-edited and republished as a school-book, especially the edition by Playfair. S. also published along with his edition of 'Euclid,' a list of Euclid's 'Data,' of which he subsequently issued a second edition; but of his other works, some of which were almost ready for publication, none were printed till after his death. He retired from his professorship in 1761, and employed himself chiefly in the correction of his various works till his death, October 1, 1768. Eight years after S.'s death, Earl Stanhope caused to be published (for private circulation) at his own expense, the work on Porisms, the two restored works of Apollonius, a posthumous tract on Ratios, and another on Logarithms; and an edition of Pappus, which was discovered after S.'s death, was presented to the university of Oxford.

SIN is the name given by theologians to the evil of human nature, to the moral defect or perversion which appears as an inherent quality of the human will, and in a greater or less degree unavoidably characterizes it in this life. It is something more than evil as affirmed of the external world or of the lower creation. *Evil*, as denoting decay or corruption in nature, is admittedly a mere relative term, for in truth decay is just as normal a process of creation as renovation, and corruption is the condition of restored health and beauty. In a similar manner, evil such as it exists in the lower animal creation, in the form of *prey* and in the forms of pain, of sickness, and of death—whatever be the special view taken of such phenomena—is never reckoned evil in the sense of *Sin*. In order to constitute the special idea of sin, it is always necessary to suppose a moral element in the evil to which it is applied. Whatever form of evil is independent of the human will as its source, origin, or agent, is not sin. Theologians, indeed, speak of original sin, or the sin of human nature, as distinguished from actual sin, or the particular transgression of the individuals composing mankind. According to a common theological view, men are not only sinners individually, but they are partakers of a sinful nature, with which their will has had nothing to do—with reference to which they have had no choice of good or evil. The evil has come to them by natural descent from the original parents of the race. But even the most extreme view of original sin preserves a hypothetical relation between every individual will and the primal transgression which it considers to be sin, not merely in those who committed it, but in those who have descended from them. All mankind are supposed to have been in Adam, the first sinner, as their representative, so that 'they sinned in him and fell with him in his first transgression.' Without such a hypothesis of unity between Adam and his race, so that his will was in some measure the typical or representative will of the race, the notion of original sin could not be maintained. For the relation between sin and will as a moral power, having the choice of good and evil, is a cardinal relation without which it would seem impossible to distinguish sin as a quality from other forms of evil in the world.

SI'NAI, the mount on which, according to the Pentateuch, God announced to Moses the ten commandments and the other laws by which the Israelites were to be bound. Its exact position is matter of dispute among travelers, but it is to be sought for in the mass of granite and porphyry mountains occupying the greater part of the Arabian peninsula, lying between the Gulf of Suez and Akabah, and rising to a height of 8000 or 9000 feet above the sea. This mountain-mass is divisible into three groups, a north-western, reaching, in Mount Serbal, an elevation of 6340 feet; an eastern and central, attaining, in Jebel Katherin, a height of 8160 feet; and a south-eastern, whose highest peak, Um Shaumer, is the culminating point of the whole Sinaitic range. Serbal, with its five peaks, looks the most magnificent mountain in the peninsula, and is identified with S. by the earlier Church Fathers, Eusebius, Jerome, Cosmas, &c.; but it does not meet the requirements of the Hebrew narrative, and even as early as the time of Justinian, the opinion that Serbal was the S. of Moses had been abandoned, and to a ridge of the second or eastern range that honor had been transferred, the northern summit of which is termed Horeb; and the southern, Jebel-Mûsa, or Mount of Moses, continues to be regarded by the great majority of scholars as the true Sinai. Its height is variously estimated at from 6800 to 7100 feet above the sea.

At the eastern base of Jebel-Mûsa, in the ravine of Shouaib, stands in solitary peace the famous monastery of Mount S.; but

in earlier times the mountain had numerous other convents, chapels, and hermitages.

SINA'PIS. See MUSTARD.

SINCERE BRETHREN, or TRUE FRIENDS, is the name of a semi-religious, semi-scientific Mohammedan order, the beginnings of which are shrouded in obscurity, but which, about 970 A.D., manifested its existence by one of the boldest and most comprehensive literary undertakings—viz., an encyclopædic treatment of philosophy, theology, science, ethics, and metaphysics, in a series of no less than fifty-one treatises. Under the head of MOHAMMEDAN SECTS, and more especially under MOTAZILITES, mention has been made of that immense religious struggle that arose but a few generations after Mohammed, in the bosom of Islam, bringing forth sect after sect; and which, under whatever name and warcry, simply denoted the reaction of the thinking minds against the dead-weight of dogmas and formulas, such as the successors of the Prophet tried in his name, and often enough in direct contradiction to his explicit dicta, to impose upon the Faithful. What the Motazilites had attempted was the reconciliation of scientific speculation, as it had irresistibly grown up at the first contact of the Arabs with Greek literature, with the religious dogma of Islam. This new period of development of Arabic culture, which chiefly characterizes the epoch of the first Abbaside rulers, however, was of no long duration. The representatives of the 'orthodox' schools, who would not hear of reconciliation, but insisted all the more uncompromisingly upon the most literal interpretation, dexterously used against them those same weapons of dialectics which their adversaries themselves had first taught them how to wield.

Setting to work with proper systems and methods, they soon built up a scholastic edifice of theology, not easy to be attacked without the most direct outspokenness; and from this the new schools, the terror of the califate strong upon them, shrank. It was thus that the Motazilites soon disappeared from the arena. But their labors had not been in vain. Silently and by small degrees this new and mysterious union of the Sincere Brethren arose. Though widely spread, their schools, their houses of assembly, their rules, their doctrines—everything remained, for we do not know how long, a profound mystery; and apart from that which they themselves have thought fit to reveal of it, neither ancient nor modern investigation has been able to discover many traces of their inner organization and activity. Not even many of their names have come down to us, though the 'treatises' they have left point to a multitude of authors, and to many stages of development. The tone of these treatises is much more free, and their entire tendency more radical than that of any of the books of their predecessors. Yet, the desire not to offend the less advanced in religious matters, and above all, to reunite rather than to make the breach wider, is perceptible in their endeavor to use what Koranic quotations and traditions can be pressed into the service of free thought, by often very unnatural processes of allegory and mysticism.

Before speaking of the treatises themselves, we shall briefly summarize what can be gathered as to the mutual relations of the brethren of this secret lodge, and the aims of their association. There is special mention made of the 'secret doctrine' which the Brethren should communicate to each other in their houses of assembly at those 'stated periods,' at which no stranger was to be admitted on any condition. The principal subjects towards which their conversation was to be directed were to be the knowledge of the soul or psychology, the knowledge of the action of the senses and the things perceptible through them, the contemplation and investigation of the mysteries of the sacred books, of the prophetical revelations, and the ideas contained in the divine laws. Their attention was further to be directed towards the four 'mathematical' sciences—arithmetic, geometry, astronomy, and (musical) composition. But the chief subject of their investigations should be the knowledge of divine things, which are the end and aim of all study. The most catholic spirit was to prevail among them with regard to the various sciences, systems, or books; since 'our own system comprises all, without exception, and includes all science.' 'The speculations of our school extend simply to all things—the sensual and the intellectual—from the moment of their beginning to their end, according to their outer and inner life—that which is palpable and clear about them, and that which is hidden and secret—the Truth, in fact. For the true essence in everything is derived from one primeval origin and general cause, since there is but one world and one supreme mind, to which all the most manifold phenomena, species and kinds, and divisions, are to be traced back.' With these words, the encyclopædic tendency of the lodge and their essays is best characterized.

All their knowledge they traced back to four sources—as indeed this number seems to have played a very considerable part in all their divisions—as follows: 1. 'The books that are known by the names of the sages and philosophers, in as far as they belong to mathematics and natural history.' They do not indicate them further; but it is easy to see from the treatises themselves that they allude to the translations of Greek works bearing the names of Pythagoras, Aristotle, Euclid, Ptolemy, Porphyry, &c. 2. 'The revealed writings derived from the prophets,' such as the five Books of Moses, the Gospel, the Psalms, the Koran, and other writings of prophets who had received their contents through inspiration by the angels and the 'deep mysteries hidden in these books.' 3. 'Books treating of nature'—i. e., that describe and represent the things now in existence—the celestial circles, the motions of the stars, the transformation of matter, the individual species and kinds of animals, plants, &c. 4. 'The divine books, or the books on the divine things, written by the angels from the tablet of Fate, upon which all the divine decrees regarding the world and man are inscribed. These contain all that refers to substances, species, kinds, and orders of the different souls; their actions, destinies, metamorphoses, phase after phase, the heavenly conjunctures and periods,' &c.

The encyclopædia of treatises which this secret association has left as the monument of its existence, was first compiled at Basrah about 1000 A.D.; but has (save one often reproduced chapter, called 'The Contest between Man and Animal') never been printed. The 51 treatises are divided into four classes: 1, the 'Mathematical,' in 13 dissertations or treatises; 2, the 'Physical,' in 17; 3, the 'Origins' of mental activity, or the thinking soul, in 10; and 4th and last 'The Divine Law,' in 11 treatises, the last of which contains a general outline of the whole work. The 'Mathematical' section comprises also Arithmetic, Astronomy, Geography, Music, and an introduction to Philosophy and Logic.

Great interest attaches to this production, as the earliest Encyclopædia deserving the name, reflecting, as it does, the state of science both of the East and West at the end of the first thousand years after the introduction of Christianity. The fifty-one treatises are neither strictly systematically arranged nor methodized, nor free from repetitions, and by no means so instructive in detail as the enumeration of the contents would lead to believe; yet they belong to the most comprehensive and creditable efforts of the human mind.

One of the most attractive portions of the work, and the one which alone has been repeatedly edited and translated into many languages (not into English), is the so-called 'Contest between Man and Animal,' which forms a part of the twenty-first treatise. In this one place alone, man and animals are introduced speaking; in all other portions, rhetoric, ornamented by allegories and metaphors, mostly well chosen and artistically wrought, forms the ordinary style. These dissertations may not have fulfilled their purpose any more than did the whole lodge; but they will be all the better appreciated when that darkest period of Mohammedan history, the 10th c., is taken into consideration. Hypocrisy stood for piety at the courts of the many emirs, low cunning for wisdom, the vilest adulation for fidelity, and oppression for justice. No wonder this manly and scientific protest was not received very favorably by so corrupt a generation. Besides which, the want of strict logical arrangement—a circumstance owing probably to the voluntary suppression of the intermediate portion—and the vagueness in which many of the most important points are treated, made even the few independent and faithful minds fail to appreciate it.

The chief cause of the discontent which they excited among the contemporaries lay in their conciliatory tendencies. Theology pure and simple would not hear of philosophy. Religion, the orthodox champion said, was a revelation—divinely given, not to be understood even by human intelligence; philosophy, on the other hand, was a vain thing, treating of human things and other futile subjects. The philosophers, though they dared not be quite so outspoken on theology, felt no less keenly that there was no compromise possible under these circumstances, even if they had not repudiated any notion of being 'reconciled.'

We have treated this subject somewhat more fully than usual, both on account of its deep intrinsic interest, as forming the most striking refutation of the commonplace notion that the religion of Mohammed was a stationary, hard, fanatical, and dotard creed, never questioned or reasoned upon by the Faithful; and further, because little or no information on the subject is generally accessible. The work itself has, as we have said, with the exception of the one fairy-tale fragment, never been edited; and there are, even among the authorities on Mohammedan matters, but three or four who have paid special attention to this important subject, and what fragmentary information we possess lies scattered in Oriental 'Transactions,' in notes, and in prefaces.—See Sprenger, in *Asiatic Journal* of Bengal; Flügel, in *Deutsche Morgenl. Zeitschrift*; De Sacy, *Notices et Extraits;* Dieterici, *Mensch und Thier;* Nauwerck; &c.

SINCLAIR, THE FAMILY OF. The Scottish historical House of Sinclair or St. Clair is of Norman descent, the surname (Latinized *De Sancto Claro*) being doubtless derived from possessions in

Normandy. Two families bearing this surname, whose connection cannot now be traced, the St. Clairs of Rosslyn and of Herdmanston, appear in Mid-Lothian and East Lothian in the beginning of the 12th century. Henry St. Clair, *Vicecomes* of Richard Morville, Chancellor of Scotland, obtained, in 1162, a charter of the lands of Herdmanston, which have ever since continued in the family. His descendant rendered signal service to Robert Bruce, for which he is said to have presented him with a sword, still in the possession of the family, with the words inscribed: 'Le roy me donne, St. Clair me porte.' The ancestor of the other line was William St. Clair, who had Rosslyn confirmed to him by charter from David I. His descendant was, like his contemporary of the Herdmanston line, a companion-in-arms of Robert I., on whose death Sir William St. Clair of Rosslyn was one of the knights selected to accompany the good Sir James Douglas, with the heart of his sovereign, to Jerusalem. With the Douglas, he fell in battle against the Moors in 1330. But the fortunes and importance of the family were principally due to the marriage of the son of this Sir William with the daughter of Malise, Earl of Strathearn, Caithness, and Orkney, and heiress of the Norwegian Jarls of the Orkneys. In this way the St. Clair family acquired the Earldom of Orkney, coupled with some very stringent conditions of fealty to the king of Norway, which would have rendered it impossible for him, in the event of a war between the countries, to have retained both his Scotch and his Norse possessions.

The Orkney earldom was, however, acknowledged and confirmed to him by Robert II.; and for the next two generations the power of the family continued to be little less than princely, the St. Clair influence being further increased by intermarriages with near relatives of the royal house of Scotland, William, the third Earl, held the high offices of Lord Admiral, Lord Justice-general, Lord Chancellor, and Lord Warden of the three Marches. He was made Earl of Caithness in 1450. At his castle of Rosslyn he kept up an almost regal state and pomp. He founded and endowed a collegiate church there, bringing skilled workmen from foreign parts to build that rich and elaborate chapel, which is still among the architectural gems of Scotland, and in its style more resembles the churches of Spain than those of North Britain. His daughter was given in marriage to Alexander, Duke of Albany, son of James II. On the marriage of James III. with Princess Margaret of Denmark, the sovereignty of the Orkneys was made over by King Christiern in mortgage to the Scottish crown, a transaction which eventually led to the permanent cession of these islands. The earl soon after resigned into James's hands his earldom of Orkney, with the islands of Orkney and Shetland, and as a compensation—it has been said, a very inadequate one—obtained the lands of Dysart and Ravensheugh, and the castle of Ravenscraig in Fife. He was still Earl of Caithness and Lord Sinclair, and from the extent of his possessions one of the most powerful nobles in Scotland. Instead, however, of keeping these possessions united, he partitioned them among his three sons in such a way as contributed far more than the loss of the Orkneys to break down the family influence. On William, his eldest son, he bestowed merely the lands of Newburgh, in Aberdeenshire; on his second, Sir Oliver, he settled all his estates south of the Tay; while, with consent of the crown, he conveyed the earldom of Caithness to his youngest son, also named William.

LORD SINCLAIR.—The eldest son of this last Earl of Orkney endeavored to set aside his father's settlement, by which he had been postponed to his younger brothers, and succeeded at last in effecting an arrangement by which Sir Oliver made over to him all the Fifeshire estates, while he renounced all claim to Rosslyn, and the other lands in the county of Edinburgh. He was still Lord Sinclair, and on his death, on the field of Flodden, he was succeeded by a line of Lords Sinclair, who ranked among the more considerable of the Scottish nobility. His grandson, by a daughter, was the notorious Earl of Bothwell, third husband of Queen Mary, and whom, in memory of his maternal descent, that unhappy queen created Duke of Orkney. The seventh Lord Sinclair had no male issue, but a daughter, married to St. Clair of Herdmanston, the representative of the other House of Sinclair already alluded to. The son of this marriage, in virtue of a new patent obtained from Charles II., became eighth Lord Sinclair—this patent, singularly enough, bringing in, on failure of heirs male, his paternal relatives, the St. Clairs of Herdmanston, strangers in blood to the former Lords Sinclair. The contingency provided for occurred in the next generation. The two sons of the eighth lord having died without issue, the title went to the Sinclairs of Herdmanston, who have ever since inherited it.

EARLS OF ROSSLYN.—Rosslyn had been purchased by one of the sons of the eighth Lord Sinclair from the last of Sir Oliver's line, and while the title thus went to an entirely different line, the estates, both of Rosslyn and Dysart, were carried by destination to the issue of the eighth lord's second daughter, whose grandson, Sir James Erskine of Alva, succeeded to the earldom of Rosslyn, which had first been conferred on his maternal uncle, the Lord Chancellor Loughborough.

SINCLAIRS OF ROSSLYN.—Sir Oliver, the above-mentioned second son of the last Earl of Orkney, was progenitor of a line of barons who, for two centuries, owned the splendid domains of Rosslyn, and where buried in the vault of the chapel, in royal fashion, in their armor. Sir Oliver's second son was the noted Oliver Sinclair, the favorite of James V., whom, to the general disgust, he placed in command of the army sent to encounter the English in 1542. To the repugnance of the army to serve under him, is attributed the disgraceful rout of Solway Moss, where 10,000 Scottish troops fled at the sight of 300 English cavalry, to whom they can hardly be said to have made any resistance. Among the functions discharged by the Sinclairs of Rosslyn were those of protectors of the gipsy race, and hereditary grand-masters of the Masonic fraternity of Scotland. The last of Sir Oliver's line, impoverished by the political troubles in which his support of the Stewarts had involved him, sold Roslyn, which then became, as has been already seen, the property of the disinherited elder branch.

EARLS OF CAITHNESS.—This title was, as has been seen, conferred on William, the youngest son of the last Earl of Orkney, and has been ever since held by his descendants, passing repeatedly from one branch to another on the failure of the direct line. The third earl, ambitious enough to aspire to be an independent prince, endeavored, in 1529, by force of arms, to recover the Orkneys from the crown. He was joined by his cousin, the second Lord Sinclair, but this foolish expedition met with a signal defeat. The support of the islanders had been calculated on: but the large majority of them turned out to be steady in their loyalty, and encountered the insurgents in a naval battle, in which the earl with 500 men were slain, and Lord Sinclair and the rest made prisoners. The sixth earl, having got into difficulties, conveyed his lands to his powerful creditor, Sir John Campbell of Glenurquhy, afterwards first Earl of Breadalbane, who, in 1677, got a patent creating him Earl of Caithness, and took possession of the Caithness estates. He was dispossessed, however, by George Sinclair, the heir-male, who entered Caithness with an armed force, and was eventually found to have the sole right to the title and estates. The Sinclairs of Ulbster are sprung from a legitimated son of William Sinclair, second son to the fourth Earl of Caithness, to whom the valuable and extensive lands of Ulbster were conveyed in 1596 and 1600 by the fifth earl. See SINCLAIR, SIR JOHN.

A genealogical history of the St. Clairs of Rossyln, written by Father R. A. Hay, was printed privately at Edinburgh in 1835.

SINCLAIR, SIR JOHN, an eminent agricultural improver, and patriotic Scottish gentleman, was born at Thurso Castle in 1754. He represented the Sinclairs of Ulbster, a branch of the noble House of Caithness. After a careful education, completed at Oxford, he studied law, and was admitted a member of both the Scottish and English bars, but having, in his 16th year, succeeded to the family estate, he devoted himself to his duties as a northern landlord, and to the more engrossing pursuits of public life. In 1780, he was returned to parliament for his native county, which he represented for many years. He wrote pamphlets on public affairs—on the navy, the militia force, the national finances, &c. In 1784, he published a *History of the Revenue of the British Empire*, an elaborate work in two 4to vols.; and in 1786 he was created a baronet. He traveled over Europe, gathering information on economical and commercial questions, and on his return set about establishing a society in Scotland for improving the breeds of sheep and the quality of wool. His exertions also led to the formation of the Board of Agriculture in 1793, of which he was president for 13 years. This institution was the precursor of numerous agricultural associations, by which the country was greatly benefited. Sir John's most important undertaking was originating and carrying through the *Statistical Account of Scotland*, completed in the year 1798 in 20 large vols., and comprising a description of every parish in Scotland. The parochial clergy were the chief contributors, but the indefatigable baronet also employed statistical missionaries, and was for seven years actively engaged in prosecuting the work. Sir John wrote on all manner of topics, including even a tragedy and treatises on health and longevity; and his publications during 50 years of ceaseless exertion are said to amount in number to 367! Not one of the whole seems destined to live; their value perished in the using; but the long and active life of their author was highly beneficial to his country. The venerable baronet died at Edinburgh, December 21, 1835, in the 82d year of his age.

Sir John S. left a numerous family, some of whom have attained to distinction. CATHERINE SINCLAIR, fourth daughter of the deceased baronet, was the author of a number of tales and descriptive works—*Modern Accomplishments*, *Modern Society*, *Scotland and the Scotch*, *Shetland and the Shetlanders*, &c., which all evince literary taste and talent, combined with fine moral feeling; while her practical benevolence and social kindness greatly endeared her to her friends, and to Edinburgh society generally. Miss S. died, universally regretted, in 1864, aged 63.

SINDE, an extensive province of British India, lies in the extreme west of that territory, and is bounded on the N. by Beloochistan and the Punjab, E. by Rajputana, W. by Beloochistan, and S. by the Arabian Sea and the Great Western Runn, an extensive lacustrine inlet which separates S. from Cutch. It is 380 miles in greatest length, 280 in greatest breadth, contains 46,599 (besides a tributary area) English sq. m., with a pop. (1872) of 2,192,415. The sea-coast, which extends north-west for 150 miles, is very low and flat, with the sole exception of the small portion beyond Karatchi (Kurrachi), and is studded here and there with low mud-banks formed by the Indus, or with sand-hills the accumulated drift from the beach; it is overflowed at high tide to a considerable distance inland, and is hardly visible, according to Burnes, at a league from shore. The province is traversed through its whole length by the Indus (q. v.), which, on approaching the coast, divides and subdivides into a number of channels, forming a delta of 75 miles in length by 130 in breadth. This delta, unlike that of the Ganges, is almost wholly destitute of wood, and the soil consists of a mixture of clay, sand, and vegetable mould, which is speedily baked hard by the heat. Along each bank of the Indus is an alluvial tract of great fertility extending 2 to 12 miles from the river, and mostly irrigated by artificial canals and watercourses, which, overflowing during the inundations, cover the soil with a silt so rich as to yield two, and sometimes three, crops in a year. The soil, nevertheless, contains in the north so much saltpetre, and in the south so much salt, that after the year's crops have been obtained, these substances are extracted for home consumption and export.

Between the Indus and its most easterly branch, the Narra, is an alluvial 'doab,' averaging 75 miles in width, but which, from want of irrigation, has become almost a desert. East of this, on the other side of the Narra, is the *Thur*, a desert of shifting sand. West of the Indus the country is occupied by the desert of Shikarpur on the north, a desert not of sand, but of alluvial clay, the same as that of the delta, which only requires irrigation to render it fertile; and in the south it is traversed by the Hala Mountains. The *Thur*, or eastern desert, has numerous vestiges of former towns, in the shape of heaps of fragments of bricks and pottery. The climate of S. is remarkably sultry and dry, it being completely beyond the action of the south-west monsoon; at Haidarabad, the fall of rain in one year was 2½ inches, and the average annual fall at Karatchi does not exceed 6—8 inches, and Larkhana has been known to be destitute of rain for three years in succession; the average maximum heat for six months at Haidarabad was 98.5° in the shade, and is still greater in Upper Sinde. There are generally two harvests per annum; the first, or *rubbí* (spring) harvest, consists of wheat, barley, oil-seeds, millet, durra, opium, hemp, and tobacco; the second, or *kurîf* (autumn) harvest, of those crops whose ripening requires much heat, as rice, sugar-cane, cotton, indigo, maize. The population consists of a mixture of Juts (a Hindu race) and Beluchis, with a few Afghans in the north-west; the greater portion of them are Mohammedans, and the remainder, who profess Hinduism, have fallen far from the strictness of observance which characterizes the most of its followers. Generally, the Sindians are tall and handsome; the Beluchi portion of them warlike and independent; the Juts peaceable, and given to agricultural pursuits.

From the time (711) that S. was conquered by the calif, Abdul-Melek, it underwent numerous vicissitudes, forming at times a part of the empire of Delhi, and being latterly (1756) joined to Afghanistan. In 1779, the Beluchis rebelled, deposed their ruler, defeated the Afghans (1786), and raised their leader, the chief of the Talpûr tribe, to supreme power. This chief made large grants of territory to various of his relatives, reserving most of Lower S. for himself and his three brothers; so that there were four 'ameers' at Haidarabad, three at Khyerpûr, and one or two at Mirpur. The ameers of S. always regarded the British government with suspicion, and occasionally troubled those traders who visited their dominions; but they subsequently concluded commercial treaties, which were observed with punctuality. On the outbreak of the Afghan war in 1838, the British government intimated its intention to take temporary possession of Shikarpûr, and forced the ameers of Haidarabad and Mirpur to agree to a treaty which virtually destroyed their independence. Their expression of a natural dislike at the mode in which they had been treated, provoked fresh demands from the Calcutta government, to which the Haidarabad ameers agreed, despite the clamors and threats of their followers, who attacked the British residency on the following day. Sir Charles James Napier, the British envoy, at the head of a considerable military force, then marched against the enemy, totally routed them at Meeanee (17th February 1843), and by defeating the ameers of Mirpur, at Dubba, near Haidarabad (March 24th), completed the subjugation of Sinde. The conquered territory was divided into three collectorates—Haidarabad, Karatchi, and Shikarpûr; the ameer of Khyerpûr, by continuing faithful to the British, retaining his dominions. For two years afterwards, Napier was actively employed in reducing the marauding tribes of the west, who pillaged the province; and so successful was the 'Sheitanka bhai' (Devil's Brother), as the robber tribes named him, that they were completely rooted out of their fastnesses, and most of them transported to distant regions. The country is reported as rapidly improving under its present administration.

SINDHU (from the Sanscrit *syand*, which in its older form probably was *syandh*, to trickle or flow) is the ancient name of the river Indus and the country along the Indus or Sindh.

SI'NDIA, the name of a powerful family of Mahratta chiefs and princes, which occupies a conspicuous place in the history of India during the 18th and 19th centuries. The founder of the family was RANOJEE SINDIA, a Sudra of the Kûmbi ('cultivator') tribe, who from a menial station in the household of the Peishwa, rose to a high rank in the body-guard, and after 1743, received in hereditary fief the half of the extensive province of Malwa. His son, MADHAJEE SINDIA (1750—1794), joined the Mahratta confederation, and was present at the battle of Paniput (1761), where he was so desperately injured as to be left for dead, but he speedily recovered, and on the retirement of the Afghans and their allies, repossessed himself of his hereditary dominions. On the death of Mulhar Rao Holkar (q. v.), he became the chief of the Mahratta princes, and had the command of the Peishwa's body-guard; and in 1770, the Peishwa and his two powerful feudatories, S. and Holkar, aided the emperor of Delhi in expelling the Sikhs from his territories, of which the administration was handed over to S., who was now by far the most powerful of the Mahratta chiefs. The murder of the young Peishwa by his uncle, Ragoba, and the consequent expulsion of the murderer from the throne he had seized, brought S. for the first time into collision with the British, who had espoused Ragoba's cause; but in the war (1779—1782) which followed, fortune distributed her favors with impartiality, and by the treaty of Salbye (1782), S. was recognized as a sovereign prince, and confirmed in all his possessions. In 1784, he captured the stronghold of Gwalior, and in the following year marched on Delhi, to restore his preponderance in the councils of the puppet monarch, and subsequently seized Agra, Allyghur, and nearly the whole of the Doab (q. v.). The manifold advantages of European discipline had struck him forcibly during the war with the British, and, with the aid of an able French officer, he introduced it into his own army.

An army of 18,000 regular and 6000 irregular infantry, 2000 irregular and 600 Persian horse, with 200 cannon, was accordingly raised, and under the leadership of De Boigne, the officer above noticed, reduced Joudpore, Odeypore, and Jypore, three Rajpût states, and effectually humbled the pride of Holkar.—DOWLUT RAO SINDIA (1794—1827) continued his grand-uncle's policy, and during the troubles which convulsed Holkar's dominions at the commencement of the 19th c., he ravaged Indore and Poona, but was wholly routed in 1802 by Jeswunt Rao Holkar. Having joined Bhonsla, the rajah of Berar, in a raid on the Nizam (1803), he brought down upon himself the vengeance of the East India Company. The confederated Mahrattas were routed at Assaye and Argaum by Sir Arthur Wellesley; S.'s disciplined troops, under the command of French officers, were scattered irretrievably at Patpergunge (near Delhi) and Laswari by Lord Lake, and he only escaped total ruin by acceding to a treaty by which all his possessions in the Doab and along the right bank of the Jumna were ceded to the British. Gwalior was, however, restored in 1805, and from this time became the capital of S.'s dominions. S. had been taught by his reverses a useful lesson, and he declined to join Holkar, the Peishwa, and Bhonsla, in their attack (1817) on the British, and thus escaped the swift destruction which was visited upon his turbulent neighbors. During the reign of BHAGERUT RAO SINDIA, a minor, the Gwalior dominions were in such a state of anarchy, that the British were compelled to insist on certain guarantees for the preservation of tranquillity; and on these being rejected, a war followed, and the Mahrattas were routed at Maharajpûr (December 29, 1843) by Lord Gough, and at Puniaur by Major-general Grey on the same day. Gwalior fell into the hands of the British, 4th January 1844, and S. submitted to the conditions demanded of him, besides maintaining a contingent force of sepoys at Gwalior. In 1853, he was declared of age by the East India Company, and in 1858 he took the field at the head of his own army against the Gwalior contingent, which had joined in the great sepoy mutiny. But the most of his troops deserted him during the battle (June 1), and he narrowly escaped by fleeing to Agra. S. was subsequently reinstated by Sir Hugh Rose, and received from the British government numerous testimonials of its grateful respect. He is a Knight Grand Cross of the Order of the Bath.

SI'NECURE (Lat. *sine cura*, without care), in common language, an office which has revenue without employment. In the canon law, a sinecure is an ecclesiastical benefice, such as a chaplainry, canonry, or chantry, to which no spiritual function is attached, except reading prayers and singing, and where residence

is not required. The strictest kind of sinecure is where the benefice is a donative, and is conferred by the patron expressly without cure of souls, the cure either not existing, or being committed to a vicar. Sinecure rectories were abolished by 3 and 4 Vict. c. 113, s. 48.

SI'NEW. See TENDON.

SINGAPO'RE, one of the Straits Settlements (q. v.), belonging to Great Britain, consists of an island lying off the south extremity of the peninsula of Malacca, in lat. about 1° 17′ N., long. 103° 50′ E., and having a city of the same name on its south side. The island is 25 miles long, and from 14 to 15 broad; area, 224 sq. miles. It is separated from the mainland by a narrow but deep strait, varying from a mile to a few furlongs in width. The surface is generally low and undulating, the greatest elevation (Bukit Tima, or the Hill of Tin) being only 520 feet. According to Malay accounts, a colony was planted on the site of the present town by tribes who are inferred to have been Javanese, from the circumstance that the name Singapura, which they gave to their settlement, is most probably of Sanscrit origin (lion-town); the Javanese being the only people in these seas who have become fairly Hinduized. Be that as it may, in 1818 it was found by Sir Stamford Raffles to be an island covered with primeval forests, sheltering in its creeks and rivers only a few miserable fishermen and pirates. It seems to have been unclaimed by any power until 1811, when the Sultan of Jahore formally annexed it to his territories.

The commanding position of S., in the very center of the highway leading from British India to China, led Sir Stamford Raffles to mark it out as the site of the first free port in the Malayan seas; and in 1819, the British flag was hoisted on the new settlement; although it was not till 1824 that Mr. Crawford concluded a satisfactory treaty with the Sultan of Jahore, whereby the island of S., and all the islands within 10 miles of its shore, were given up in full sovereignty to the East India Company, on condition of a considerable yearly payment. Since then, the prosperity of S. has been almost without a parallel. Its position as an entrepôt for the trade of the Malayan Archipelago, the Eastern Peninsula, and China, and the wise policy that placed the commerce of the port on an entirely unfettered footing, rapidly established a flourishing trade. In 1823, the imports amounted to £1,200,000; the exports to £920,000. In the year ending 30th April 1865, the value of the imports was £6,610,000; the exports, £6,630,000, being fully double the amounts in 1854—1855. Notwithstanding the opening up of more direct communication with Europe of many of the markets in China, Cochin-China, and Siam, formerly largely supplied by traders from S., the commerce has increased, and in 1880 the value of imports was £16,743,620, and of exports, £15,610,347. This shows that both exports and imports had doubled within the past ten years.

The imports to the United Kingdom in 1880 amounted in value to £3,697,624, and the exports from thence to S. were £2,459,659. The local trade and the exports to the British colonies at the same time showed an increase. The chief articles of export to Europe and North America are gambir, tin, sago, tapioca, black and white pepper, tortoise-shell, nutmegs, gutta-percha, camphor, coffee, sapan-wood, and ratans. Of these, only gambir, sago, and nutmegs are produced on the island to any important extent; all the other articles being imported, chiefly by natives from other quarters. From Europe, large imports are received of cotton manufactures, woollens and linen, metals, hardware, earthenware, arms and ammunition, and treasure in the form of dollars. Large fleets of prahus are wafted by the southerly monsoon towards this great center of trade, laden with the numerous products of the Indian Archipelago, to return again laden with the manufactures of Europe. The splendid harbor of S. is well sheltered and of easy access, and lying as it does at the converging points of the great trade routes of the East, is visited by a large number of vessels. In 1880, 2120 vessels (1753 of these being steamers), of 1,693,096 tons, entered the port; and 1728 steamers, of 1,359,913 tons cleared; the coasting-trade being 4657 entered and 4694 cleared. In 1880, the local revenue of S. was £55,695; expenditure, £57,737. The total revenue of S. in 1880 was £255,482, and the expenditure, £247,905. A savings-bank was established at S. in 1877, and is now managed by a secretary immediately under the colonial treasurer. Under the new postal contract, letters can be delivered in S. twenty-eight days after the date of their leaving England. Education is being steadily advanced in S., and a zealous desire on the part of the Eurasians to learn English is now observable. One school in S. had, in 1876, an attendance of 476. It is intended to establish at S. a training school for vernacular teachers. There is already a Malay College.

The currency of commerce is the Spanish dollar; but the official currency of government is the rupee. The Chinese pecul, of 133⅓ lbs. avoirdupois, which is divided into 100 catties, is the standard of weight. The population of S. is perhaps the most heterogeneous in the world, comprising at least 16 nationalities, speaking different tongues. The Malay, however, soft and easily acquired, is the recognized medium of communication between all classes. The population amounted, in 1881, to about 139,000; in 1871, to 97,111; of whom, 61,752 were in the town of S. and its environs, 31,235 in the country, and 4124 on board of vessels. According to the census report for that year, the various races stand to each other in the following proportion: Europeans and Americans, 1946; Chinese, upwards of 54,000; Eurasians, Armenians, and Jews, 2285; Malays, and Klings or immigrants from Southern India, 37,000. Of the aboriginal inhabitants of the island, not a trace remains; but similar tribes are still to be found in small numbers in several parts of the peninsula. Of the native population, the Chinese are the most useful part; they form almost the only body of trustworthy native merchants, in the proper sense of the word, and are freely trusted to large amounts by European importers; and it may be doubted whether, as a commercial body, they are, on the whole, more deficient in morality than many European communities. The laws are those of Great Britain, with some modifications; the court is that of a recorder. S. being a free port, the revenue is raised by inland excises on opium and spirits. S. is the seat of government for the Straits Settlements (q. v.), which, on April 1, 1867, were transferred from the control of the Indian government to that of the Secretary of State for the Colonies.

The town of S., which, as we have seen, contains ⅔ds of the whole population of the settlement, is situated at the mouth of a small river, on the S. side of the island. It is the seat of government for the whole of the Straits settlements. Its appearance is of a mixed oriental and European character; the streets are generally wide, and kept in good order, and in 1864 the town was lighted with gas. There is an efficient police, and the sanitary arrangements of the town are good. The municipal council consists of public officers and ratepayers.

S. possesses two fine harbors; one opposite the town, which, although little more than an open roadstead, is a safe and convenient anchorage, where ships load and discharge by means of lighters; the other is about 3 miles west of the town, and is landlocked, and capable of admitting the largest vessels. Along its shores, extensive wharfs have been erected by steam-companies and individual merchants; and it is probable that when communication by railway with the town is established, the old harbor will be little used. There are several fortifications commanding the harbor and roads, but the increasing commercial and political importance of the place calls for a still stronger naval and military station. S. being within 80 miles of the equator, has little or no variety of seasons; the climate, although hot, is healthy; the temperature ranges from 71° to 92°; rain falls more or less on 200 days of the year, and the extent of the fall is about 87 inches. The soil of S. is not fertile, although the climate is such as to cover it with a rich and beautiful vegetation. The nutmeg was at one time successfully cultivated, but most of the trees having unaccountably died, this has been abandoned, and husbandry is now confined to the cultivation of the cocoa-nut, the pepper-vine and gambir plant, and to the raising of sugar-cane and vegetables for local consumption. The curse of S. is the tiger. It is estimated that 300 Chinamen and other natives are carried off yearly. Turtle are abundant on the shores, and form the cheapest animal food in the bazaars.—See Thomson's *Journal of the Indian Archipelago;* J. Crawford's *Dictionary of the Indian Islands and Adjacent Countries;* J. Cameron's *Our Tropical Possessions in Malayan India.*

SINGHARA NUT. See TRAPA.

SINGING, the art of producing music from the human voice, generally, though not necessarily, combined with speech. The mechanism of the vocal organs, as applicable to singing, has by some physiologists been likened to a reed, by others to a stringed instrument; in point of fact, the human voice is produced by an apparatus far beyond either in complexity of structure.

The extreme limits of the voice in respect of pitch may be considered to be from to  ; but the compass of any individual voice is limited to a portion of that range, and voices are classified according to their pitch. Generally speaking, male voices lie an octave below female. The former are divided into *bass* and *tenor*, the compass of ordinary bass voices being considered to be from  to  , and of tenor from to  . For tenor music, the tenor or C clef is

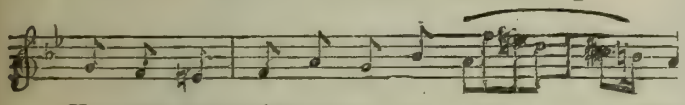
generally used , which has the advantage of having the principal tones within the staff. When the treble clef is used, the music is written an octave above its true pitch. Female voices are either *contralto* (otherwise called *alto*) or *soprano*, the former extending from  to  , the latter from  t  , or sometimes higher.

Contralto music may be noted either on the treble clef, or on the alto clef, which latter is but the tenor clef placed on the third instead of the fourth line of the staff  These are the principal divisions of voices; but there are also further subdivisions. Intermediate between bass and tenor is another male voice, called *baryton;* and intermediate between contralto and soprano, another female voice, called *mezzo soprano*. The ordinary compass of a voice is about twelve notes, but two octaves are not uncommon, and some voices have reached three. Madame Catalani is said to have possessed a voice of three and a half octaves compass.

The notes produced in singing are of two kinds, according as they proceed from the chest voice (*voce di petto*), or head voice (*voce di testa*). The chest notes, or lower register, proceed naturally and readily from the ordinary mechanism of the voice; the upper register, head voice, or falsetto, is produced by a more or less forced contraction of the cavity from which the voice proceeds, imparting to the notes a fife-like character, gentle and weak in the male voice, but often clear and sonorous in the female. It is only in the higher notes of the voice that the falsetto is used, and some notes on the borders of the two registers may be given in either. Where the two registers meet, the tones are apt to be hard and uncertain, or weak; but a cultivated singer will blend the head and chest voice at the point of junction, so as to make the break imperceptible. The notes of the bass voice are given entirely from the chest. In the tenor, the three or four upper notes belong mostly to head voice. The contralto tones are mostly chest voice, and the upper tones of the soprano are head voice. The alto, when sung, as it often is in England, by male voices, is principally falsetto.

In singing, the head should be held erect, and the chest well expanded, to allow free play to the lungs, and free emission of the voice from the throat. The tongue should be kept still, slightly pressing on the lower teeth. Proper regulation of the breath, and proper articulation of the words, are also matters of essential moment.

One particular requires to be mentioned, in which the notation of songs differs from that of instrumental music. In the latter, two or more quavers or semiquavers may be grouped together by a common line; in singing, this can only be done when the whole group are to be sung to one syllable, and notes belonging to different syllables are always written separately. When notes without hooks, or notes that are not grouped, belong to one syllable, they are bound together by a *slur* placed over them, e. g.:



Among the principal objects to be studied in cultivating the voice for singing are the improvement of its quality in respect of clearness and resources; the rendering every note in its compass equally pure; the extension of its compass, not by injudicious forcing, but by gradual practice; and the acquirement of the power to prolong any note with perfect ease. See MUSIC, VOICE, SOLFEGGIO.

SI'NGULAR SUCCE'SSOR, in the Law of Scotland, means one who succeeds in the ownership of property by purchase or any other mode than by descent.

SINIGA'GLIA, or SINIGALLIA (anc. *Sena-Gallia*), a city and seaport on the east coast of Italy, in the province of Ancona, and 17 miles west-north-west of the city of that name, at the mouth of the Misa, with 10,500 inhabitants. It is a bright, cheerful city, built after the modern style, walled round, and it has bastions and handsome gates. S. is celebrated for its annual fair, which lasts from the 20th July to the 10th August, and which sometimes puts in circulation about 60 million francs in 20 days. English, French, Swiss, Americans, Germans, &c., attend it. S. was founded by the Senonian Gauls, and colonized by the Romans 289 B.C.

SI'NISTER, in Heraldry, the left-hand side of a shield. As shields are supposed to be carried in front of the person, the sinister side is that which covers the bearer's left side, and therefore lies to the spectator's right. See POINTS OF ESCUTCHEON.

SINKING FUND. See FUND.

SINO'PÉ (Turk. *Sinub*), a town of Asiatic Turkey, province of Anatolia, on the southern side of a little promontory running eastward into the Black Sea, 80 miles north-west of Samsun. S., which is defended by some half-ruined fortifications, possesses a dock-yard, and naval arsenal; exports timber, dried fruits, tobacco, bay-leaves, and oil, and has a population of from 8000 to 10,000 souls. The bay of S., which affords the finest anchorage for ships along the whole northern coast of Asiatic Turkey, was the scene of a bloody naval engagement, or rather massacre, 30th November 1853, when a Turkish squadron of 13 ships was suddenly attacked and destroyed by the Russian fleet.—Of the ancient city of S., which was founded by a colony of Milesian Greeks, and, for 200 years after the Peloponnesian war, was almost the mistress of the Euxine, numerous ruins still exist, 'friezes, hundreds of Corinthian columns, capitals, sculptures, inscriptions, and even statues, built up into the walls of its picturesque Byzantine fortifications.' S. was the birthplace of Diogenes the cynic.

SI'NOPLE, in Heraldry (q. v.), the same as Vert.

SI'NTER, the name given by German mineralogists to those rocks which are precipitated in a crystalline form from mineral waters. They are of recent date, belonging in fact to the strata at present in course of formation. S. is of various forms, kidney-shaped, knotted, tuberous, botryoidal, tubular, stalactitic, shrub-like, or pronged, and is occasionally distinguished by its chief component, as Calcareous S., Flint or Quartz S., Iron S., &c. Calcareous S., which is a variety of carbonate of lime, composed of concentric plane parallel layers, appears under various forms; it is deposited with extraordinary rapidity by many springs, a peculiarity frequently made use of to obtain the incrustation of objects with a coating of this substance. Quartz S. is mostly found in intermittent hot springs, as in the Geysers (q. v.) of Iceland. Iron S. occurs in old mines, and in coal-beds, where it is formed from iron pyrites through the agency of the atmosphere. The tubular conglomeration of grains of sand half-melted by lightning (*blitz*) is also known as Blitz-S., or Fulgurite (q. v.).

SI'NUS (Lat. a bend or hollow) has two significations in Anatomy, and one in Surgery. The cells or cavities contained in certain bones—as the frontal, ethmoid, sphenoid, and superior maxillary—receive this designation. The frontal sinuses are two irregular cavities extending upwards and outwards, from their openings on each side of the nasal spine, between the inner and outer layers of the skull, and separated from one another by a thin bony septum. They give rise to the prominences above the root of the nose called the nasal eminences. They are not developed till after puberty, and vary considerably in size, being usually larger in men than in women and young persons, in consequence of the greater prominence of the superciliary ridges in the former. When very much developed, they give a receding appearance to the forehead.

They are larger in Europeans than in negroes, and are very imperfectly developed in the Australians, whose peculiar want of vocal resonance is apparently due to this deficiency. They communicate on each side with the upper part of the nostril by a funnel-shaped opening, which transmits a prolongation of mucous membrane to line their interior. These cells are much more highly developed in certain mammals and birds than in man. Professor Owen observes that 'they extend backwards over the top of the skull in the ruminant and some other quadrupeds, and penetrate the cores of the horns in oxen, sheep, and a few antelopes. The most remarkable development of air-cells in the mammalian class is presented by the elephant; the intellectual physiognomy of this huge quadruped being caused, as in the owl, not by the actual capacity of the brain-case, but by the enormous extent of the pneumatic cellular structure between the outer and inner plates of the skull.' The sphenoidal sinuses are two large

irregular cavities, formed, after the period of childhood, in the body of the sphenoid bone. They communicate with the upper part of the nose, from which they receive a layer of mucous membrane. Like the frontal sinuses, they serve to lessen the weight of the skull, and to add to the resonance of the voice. The ethmoid sinuses or cells lie in the lateral masses of the ethmoid bone. They open into the cavities of the nose. Their main use is to diminish the weight of the fore-part of the skull. The superior maxillary sinus commonly known as the *Antrum of Highmore* (the anatomist who first accurately described it) is the largest of the facial sinuses. Its uses are the same as those of the others, and like them, it communicates with the nasal cavities.

The *sinuses of the dura mater* are quite distinct from the above-described bony sinuses; they are irregular channels for the transmission of venous blood, and are formed in the following way. The dura mater consists of two layers—an outer, belonging to the skull; and an inner, belonging to the brain. They can be easily separated in infancy, but in the adult they are blended together for the greater part of their extent. In some places, however, as beneath the sagittal suture (formed by the two parietal bones at the top of the head, and running from before backwards), they are separated on either side of the mesial line, the outer layer being continued beneath the bone, and in contact with it; while the inner one dips inwards, and meeting with the corresponding layer of the opposite side, forms a triangular canal or sinus, which is strengthened at the sides and angles by interlacing bands of fibrous tissue. The sinus whose formation we have thus described is called the superior longitudinal sinus, and the other sinuses are formed in the same way. They are all lodged in the intervals between the great divisions of the brain, and they are so constructed 'that their shape cannot easily be altered by any external pressure; consequently, the flow of blood through them cannot be impeded by the pulsations or pressure of the brain, in the varying positions of the body. The tense, unyielding character of their walls, moreover, does not admit of either collapse or distention; hence, they must be equally full at all times, and must exert a uniform pressure on the brain.'—Humphry *On The Human Skeleton*, p. 200.

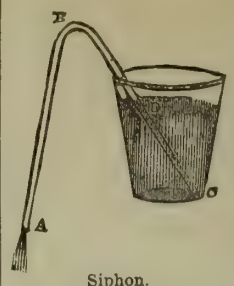
In Surgery, the term *sinus* is nearly equivalent to *Fistula* (q. v.).

SION, a small town of Switzerland, capital of the canton of Valais, in a picturesque situation on the right bank of the Rhone, 18 miles north-east of Martigny by the Simplon Railway. It is defended by walls, towers, and a ditch, and contains a large cathedral, a handsome Gothic town-house, a Jesuit's convent, and an ancient prison. On the north of the town is a lofty rock, divided into two peaks by a deeply-cut ravine. On the highest peak is the ruined castle of Tourbillon, built in 1294; on the other, the castle of Valeria, now used as a seminary. An excellent wine, called Malvoise, is made here. S. is called *Civitas Sedunorum* in a still existing inscription in honor of Augustus, to be seen in the cathedral; in the middle ages it was named *Sedunum*. Pop. (1870) 4895.

SIOU'T, also *Es-Sioût*, and *Osiût*, the chief city of Upper Egypt, stands near the western bank of the Nile, and is 200 miles in direct line south of Cairo. It has several fine mosques, bazaars almost as well furnished as those of the capital, some good baths, and one or two well-built houses. S. manufactures great quantities of the best pipe-bowls. It is the residence of the governor of Upper Egypt; the resort of the caravans from Darfur, that come by the way of the Great Oasis, and until recently was the principal seat of the Egyptian slave-trade. Pop. about 25,000. S. is built on the site of the ancient Lycopolis, but few remains of the Græco-Egyptian city are extant. From the neighboring heights of the Libyan mountains, which contain numerous rock sepulchres, the view over the valley of the Nile is, in the opinion of Lepsius, the finest in Egypt.

SIOU'X, a tribe of North American Indians, calling themselves also Dacotahs, inhabiting Dacotah territory. They are a brave and warlike people, generally at war with the Chippeways. Formerly they numbered 30,000, and counted 7000 warriors; at present their whole number is estimated at 23,250. Roman Catholic missions were established among them 200 years ago, and Presbyterian missions recently. The S. are more advanced towards civilization than any tribe of the North-west.

SI'PHON is a tube bent so that the two legs are either parallel, or incline at an acute angle, and is employed to draw off liquids from vessels which it is not convenient or desirable to move. If the end of the short leg of a siphon be plunged into the liquid, and the other leg be suffered to hang outside the vessel, then, whenever the siphon is exhausted of air (a process which can be performed by suction by the mouth or a pump, or by filling the tube with the liquid it is employed to decant, and keeping it so filled till it is placed in its proper position), the liquid will at once flow out of the vessel through the tube, and continue to do so either till it falls below the level of the outside end, or till the inside end ceases to be immersed. The principle of this simple and efficient instrument is easy of explanation: let ABC (fig.) be a siphon with one leg, BC, partially immersed in liquid, and suppose the whole siphon filled with the same liquid; then at A we have the pressure of the atmosphere acting upwards into the tube in opposition to the pressure of the liquid in the leg BA; at C we have the pressure of the atmosphere (transmitted through the liquid), and the pressure of the liquid in the vessel outside (which balances an equal height of liquid inside) the tube, acting upwards into the tube in opposition to the pressure downwards of the liquid in the leg BC.



Siphon.

The effective pressures inwards at A and C are, respectively, the atmospheric pressure less by the pressure of the liquid in BA, and the atmospheric pressure less by the pressure of the liquid in BD; and as the latter of these two is the greater, it overcomes the other, forces the liquid in the tube out at A, and that in the vessel into the tube at C, the process continuing till the liquid falls to the level of C (when air is admitted), or of A (when the two pressures become equal). It is evident from the above explanation that when A is on or above the level of D, the surface of the fluid, there can be no flow through the tube; also, that it is quite immaterial whether the longer or the shorter leg be immersed, if only A be below the level of D. If the bend of the siphon be 33 feet for water, or 30 inches for mercury, above D, the pressure at C, which produces the action of the siphon, becomes the weight of the atmosphere, diminished by an equal weight of a column of fluid, in which case the resulting pressure is zero, and there is no flow through the tube. The flow increases in rapidity and force as the difference of level between D and A increases, and as the difference of level between D and B diminishes. Many siphons have a suction-pump permanently attached to the end of the outer leg for the purpose of exhausting the air inside. Another variety is the *Wurtemberg siphon*, which has two equal legs, the extremities of which are bent upwards so that when the siphon is once filled with fluid, it remains full, and is always ready for use.

SIPHONO'STOMA. See FISH-LOUSE.

SIPHONOSTO'MATA, a large group of gasteropodous molluscs, of the order *Pectinibranchiata*, having the mantle prolonged into a siphon, by which the water enters the gill-chamber. The shell is spiral, the aperture notched or produced into a canal in front, often much produced. To this group belong the families *Cypræidæ* (cowries, &c.), *Volutidæ*, *Buccinidæ* (whelks, &c.), *Muricidæ*, and *Strombidæ*. They are almost all carnivorous, and move about with considerable activity.

SIPU'NCULUS, a genus of *Echinodermata*, giving its name to a family, *Sipunculaceæ*, and to an order, *Sipunculidæ*. The *Sipunculidæ*, although ranked among the *Radiata*, and having the essential characters of that division of the animal kingdom, resemble the *Annelida* in form, general appearance, motions, and habits, as well as in their softer covering, which is leathery and

Sipunculus Bernhardus:

1, Sipunculus alive in a periwinkle shell, with the upper part of the shell broken away to show the animal's body; 2, S. freed from its shell with the trunk retracted; 3, S. with all its parts expanded, as when preserved in spirits.—From Forbes's *British Star-fishes.*

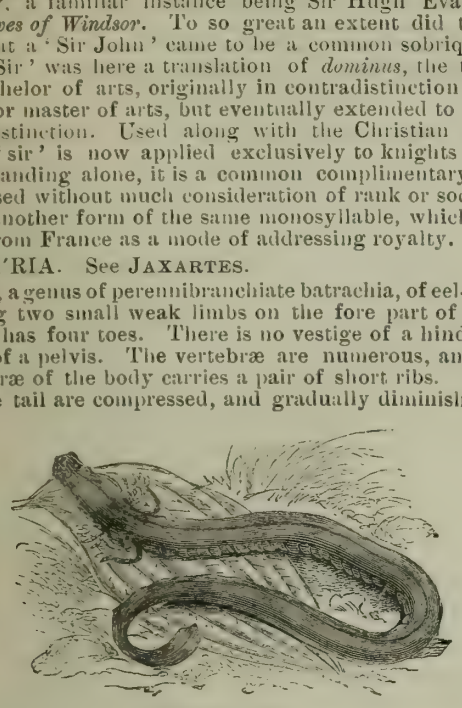
not calcareous, and in the absence of calcareous spines. The *Sipunculaceæ* have a retractile proboscis, around the extremity of which is a circle of tentacula, and at the base of it the anus. In the genus *Sipunculus* the proboscis is long and cylindrical, with a circle of tentacula near its extremity. *S. Bernhardus* is common on many parts of the British coast, living at the bottom of the sea, at a depth of from ten to thirty fathoms, and occupying as a habitation the shell of some univalve mollusc, for the protection of its soft wormlike body. It secures the entrance of the shell

by a plaster-work of sand, leaving only a hole wide enough for the protrusion of its long flexible proboscis. Other species, instead of sheltering themselves in shells, burrow in the sand. Among these is the EDIBLE S. (*S. edulis*), much esteemed by the Chinese.

SIR (Fr. *sieur* and *sire*, contracted from *seigneur;* from Lat. *senior*, elder), a term originally corresponding to *dominus* in Latin, and which has come, when appended to the Christian name and surname, to be the distinctive mark of knighthood. It was at one time the practice to use the same title in addressing the clergy, a familiar instance being Sir Hugh Evans in the *Merry Wives of Windsor*. To so great an extent did this usage obtain, that a 'Sir John' came to be a common sobriquet for a priest. 'Sir' was here a translation of *dominus*, the term used for a bachelor of arts, originally in contradistinction from the *magister*, or master of arts, but eventually extended to the clergy without distinction. Used along with the Christian name and surname 'sir' is now applied exclusively to knights and baronets. Standing alone, it is a common complimentary mode of address used without much consideration of rank or social status. 'Sire' is another form of the same monosyllable, which has been adopted from France as a mode of addressing royalty.

SIR-DA'RIA. See JAXARTES.

SI'REN, a genus of perennibranchiate batrachia, of eel-like form, but having two small weak limbs on the fore part of the body. Each foot has four toes. There is no vestige of a hinder pair of feet, nor of a pelvis. The vertebræ are numerous, and each of the vertebræ of the body carries a pair of short ribs. The vertebræ of the tail are compressed, and gradually diminish in size to



Siren Lacertinus.

its tip. The head is flattened, the mouth not deeply cleft, the muzzle blunt, the eyes very small, the ears concealed. The teeth are small; the lower jaw is furnished with them all round; there are none on the upper jaw, but two rows on each side of the palate. On each side of the neck are three gills, each consisting of a short fleshy stalk, supporting a beautiful fringe-like tuft, and water passes from the mouth to the gills through openings as in fishes. But the S. has also lungs, which are long bags, one on each side, beginning behind the heart, and extending almost the whole length of the abdomen. The blood discs are remarkable for their large size, exceeding even those of the proteus. The sirens inhabit the swamps of the Carolinas and other southern parts of North America. They live chiefly in the mud, but sometimes are to be seen swimming in the water, and even make excursions on moist ground. They feed on worms and insects. *S. lacertina* grows to the length of about three feet. Its color is blackish. The tail is compressed. The other species are smaller.

SIRÈNE, an instrument for the production of musical sounds in such a manner as to enable us to discover their ultimate nature. The simplest form of sirène is represented in section in fig. 1. A vane consisting of four equal plates, attached to a delicately supported axle, is so fixed in a metal tube as to close it almost completely (with the help of stops P, P), when either pair of plates is perpendicular to the axis of the tube. When air is forced from a bellows through the pipe A, it gives the vane a rotation in the direction indicated by the arrow, and thus produces a current which is interrupted four times in each revolution. In other words, four times in each revolution the air escapes freely, giving rise to a sound. While the vane revolves slowly, the ear distinguishes these successive puffs; but when the revolutions are more numerous than about five per second, the successive puffs cannot be distinguished, and the recurrent sounds are merged into a uniform note, whose pitch rises (i. e., it becomes more and more shrill) the faster the vane revolves. Such an instrument works well when driven by water instead of air. What it shows is, that musical sounds consist of the repetition, at equal very small intervals of time, of some definite noise. By turning the vane by means of a train of wheels, so as to give it a definite rate of rotation, the number of such repetitions per second, necessary for the production of a given musical note, may be measured.

But the sirène of Cagniard de la Tour is much more valuable for such a purpose, as it counts for itself the number of repetitions per second. In principle, it is identical with the simpler instrument just described; but the details of its construction are different. It consists essentially of two circular discs, the upper of which is free to revolve so as almost to touch the lower (fig. 2). In each a series of holes is cut, arranged at equal distances in a circle about its axis. Through the holes in the lower (fixed) plate, streams of air are admitted from a bellows, and pass through the corresponding holes in the upper (movable) plate, when the

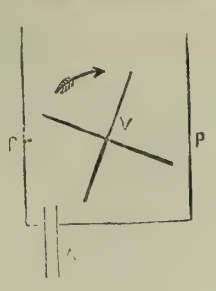


Fig. 1.

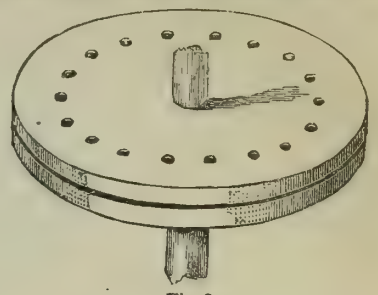

Fig. 2.

pairs of holes are superposed; but are checked when the upper plate is turned a little, readmitted when the plate turns a little further, and so on. The holes are pierced *obliquely* through the upper plate, so that the issuing stream makes it turn about its axis. The sounds given by this instrument are exceedingly pure (see SOUND) like those of the flute or tuning-fork. The axis of the upper plate carries an endless screw, which turns a light train of wheels (with dials) resembling that of a gas meter, so that when, by proper adjustment of the pressure in the bellows, the instrument gives steadily some definite note, we may observe the number of turns in any number of minutes by watch. The number of puffs is obviously to be found from this by multiplying by the number of holes in the plate, since during one turn any hole in the upper plate has been opposite each of those in the lower plate in succession. Thus we find the number of puffs per second necessary to the formation of any given musical note.

More complex forms, such as Helmholtz's double sirène, have been devised for more recondite branches of the science. See SOUND.

SI'RENS (Gr. *seirenes*, the 'entanglers,' probably from *seira*, 'a cord' or 'string') figure in Greek mythology as young maidens, who sat on the shores of a certain island or promontory near the south-western coast of Italy, and sang with bewitching sweetness songs that allured the passing sailor to draw near, but only to meet with death. Homer speaks of them in the plural, but does not specify their number; later writers mention two and three by name, and assign them various genealogies. Their tenure of life was dependent on the successful exercise of their charms. If any seaman could resist the enticements of their magic music, they were doomed, but Ulysses or the Argonauts alone succeeded in doing so. It is related by Homer, in the *Odyssey*, that when the former in the course of his wanderings approached their perilous home, he, by the advice of the sorceress Circe, stuffed the ears of his companions with wax, and lashed himself to a mast, until he had sailed out of hearing of the fatal songs. Others say that it was the Argonauts who got safely past, owing to the superior enchantment of Orpheus's singing, whereupon the S. threw themselves into the sea, and were transformed into rocks. The Latin poets give them wings, and in works of art they are often represented as birds with the faces of virgins, and are provided with musical instruments. There is obviously a close resemblance between the Mermaid (q. v.) of northern mythology, and these Græco-Mediterranean Sirens. The Loreley of the Rhine is only a river-siren, though a more exquisite enchantress than ever Greek fancy conceived.

SIRINAGUR. See SERINAGUR.

SIR-I-PUL, a town of Afghan Turkestan, 45 miles south-west from Balkh, in lat. 36° 21′ N., and long. 66° 28′ E., on a river which loses itself without reaching the Jihoon. It is the capital of an Uzbek chief. Pop. 18,000.

SI'RIUS, otherwise called *Canicula*, or the *Dogstar*, is a star of the first magnitude, the brightest in the heavens, and is situated in the constellation of *Canis Major*, or the 'Great Dog.' It is about 123 billions of miles distant from the earth. See STARS. It has long been known to possess a 'proper motion' (i. e., an independent progressive motion), which was for a time believed to be in a straight line, but has now been shown to consist of an undulatory progressive motion on each side of a middle line. This motion was investigated by Professor Peters of the Pulkowa Observatory, Russia, on the supposition that its anomalous character was produced by the attraction of some unseen neighbor, and his calculations being completed and verified (on this supposition) by Mr. Stafford of Washington, the distance of S. from the center

of gravity of both was determined to be 1495 millions of miles. In January 1862, Mr. Alvan Clark of New York, chancing to observe S. through a powerful telescope, detected a minute star (which had never before been observed) situated at an angular distance of 7″ from S., representing about 4300 millions of miles, and it is generally believed that this is the disturber in question. By photometric measurement it has been shown that, supposing the intensity of the sun's light for unit of surface to equal that of S., it would require 400 suns at the distance of S. to send us the light which that star does; and our sun at the distance of S. would appear less than a star of the sixth magnitude, and be invisible to the naked eye. The Egyptians called this star Sothis, and at one time its 'heliacal rising' (q. v.) was a sure forerunner of the rising of the Nile; while among the Romans it was considered as a star of evil omen, whose appearance above the horizon coincided with (or even caused the unhealthy and oppressive heats of summer. Hence the origin of the various superstitions regarding the Dog Days (q. v.), many of which are still current.—The term 'dog star' was also applied to Procyon, a bright star in *Canis Minor*, whose heliacal rising differs only by a few days from that of Sirius.

SIRO'CCO. See SIMOOM.

SISMONDI, JEAN CHARLES LEONARD DE, a distinguished historian of Italian descent, was born at Geneva on 9th May 1773. He received his education as a boy at the 'College' or high school of his native town. At the due age, he was removed to the Auditoire, or university. Before he had completed his education, the pecuniary reverses of his father made it necessary for S. to do something for his own maintenance, for which purpose he entered the counting-house of the eminent firm of Eynard and Co. of Lyon. Hateful as mercantile pursuits seem to have been to him, he applied himself to his drudgery with all diligence. He became a thoroughly good clerk, and in after life he acknowledged that the practical training had been of incalculable benefit to him. The French revolution sent S. back to Geneva, but the storm following, he took refuge in England, along with his family. Homesickness soon sent them back to Geneva, but the continuance of political trouble made it impossible to remain there long. In 1795, they bought a small farm near Pescia, in Tuscany, where their narrow circumstances rendered it necessary for S. almost literally to put his hand to the plough. He had now, however, leisure for literature. In 1798, he began to collect materials for his *History of the Italian Republics*. In 1803, appeared a work on political economy, *De la Richesse Commerciale*, in which he writes like a decided follower of Adam Smith, though at a later period, in his *Nouveaux Principes d'Economie Politique* (1819), he abandoned the wiser views of his youth. In consequence, a professorship in this science was in the same year offered to him in the university of Wilna, which he declined. It was in history, however, that his literary forte lay. The 16 vols. of his *Histoire des Républiques Italiennes*, published between 1807 and 1818, placed him in the first rank among contemporary historians, and brought him praise from the most distinguished men in France and Germany.

The events of the Hundred Days occasioned one of the most memorable passages in the life of S.—his interview with Napoleon. In 1813 appeared his *Littérature du Midi de l'Europe* ('Literature of the South of Europe,' Eng. by Roscoe, frequently reprinted). In 1819, he began his best and greatest work, the *Histoire des Français*, with which he was occupied until his death. On the 19th April of the same year he married Miss Allen, an English lady, whom he had previously met in Italy. This marriage was followed by many happy years during which S. resided at Geneva, making frequent visits to Pescia and England. His latter days were, however, darkened by the troubles of his native city, in whose politics he took a keen interest. He died 25th June 1842. S. has contributed more to historical literature than any other writer of his time, and the labor which he bestowed on his works has never been surpassed. 'Nine times,' he says, 'have I traversed Italy, and I have visited every place which has been the scene of any great historical event.' For twenty years he worked habitually eight hours a day. Both as a worker and as a thinker, he was thoroughly conscientious. His mind was to the last open to truth; neither fettered by prejudice nor blinded by self-conceit. At the same time, no one has surpassed him in tenacity of purpose, nor in energy in following it out. His feelings on religious questions were especially intense. Having on one occasion heard a sermon in an English church on eternal punishment, he vowed never again to enter another church holding the same creed; and 'never to contribute to spread what the English call their Reformation; for, by its side Romanism is a religion of mercy and peace.' His private character was singularly amiable and benevolent. His whole career is a noble one, full of interest and instruction.—See *Quarterly Review*, September 1843; *Vie et Travaux de Sismondi* (Paris, 1845); see also his Correspondence with Mademoiselle de St. Aulaire (Paris, 1863); and his *Letters Inédites à Madame d'Albany* (1864).

SISTERS OF CHARITY. See BROTHERS AND SISTERS OF CHARITY.

SI'STOVA, an important commercial town of the principality of Bulgaria, on the south bank of the Danube, about 35 miles up the river from Rustchuk. It has several mosques, an ancient and strong castle, where the 'peace of Sistova' between Austria and Turkey was concluded in 1791; manufactures cottons and leather, and carries on an active river-trade. Pop. (1881) 11,438.

S'ISUPALA is in Hindu legend the sovereign of Chedi, a country situated in Central India, who was the enemy of Krishn'a (q. v.), and ultimately was slain by him. The history of this enmity, and the death of S., are the subject of the *S'is'upâlabadha* of Mâgha. See SANSCRIT LITERATURE.

SI'SYPHUS, a personage of Greek mythology, whom later accounts make to be the father of Odysseus. He is said to have been founder and king of Ephyra—afterwards Corinth—and both he and his whole house were notorious for their wickedness. He is, however, best known for the punishment which he suffered in the lower world, either for treachery towards the gods, or for his wholesale robbery of travelers, whom, at the same time, he murdered with a huge block of stone. He was condemned to roll an immense boulder from the bottom to the summit of a hill, which, whenever it reached the top, rolled down again, and the task of S. had to be begun anew.

SITA is, in Hindu Mythology, the daughter of Janaka, a king of Mithilâ, and the wife of Râma. See VISHN'U. The word means literally 'furrow,' as she was not born in the usual sense of this word, but arose from a furrow when her father was ploughing the ground, whence she is also called *Pârthivî* (from *pr'thivî*, the earth). Her history is related in the RAMAYAN'A (q. v.).

SI''TKA, or NEW ARCHANGEL, the principal settlement in the territory of Alaska, is a small place of about 2000 inhabitants, on the west coast of the island of Sitka or Baranov, the largest island in the group known as George III.'s Archipelago. Lat. 57° 3′ N., long. 135° 18′ W. S. was the residence of the governor of Russian America, and has a magnetic observatory. Here the chief establishments of the Russian-American Company, incorporated 1799, for fishing and hunting fur-bearing animals, were situated. The Company employed 50 ships, and about 850 men, but their privileges expired in 1863.

SITOPHO'BIA, or SITOMA'NIA. The repugnance to or refusal of food may range from mere impairment or loss of appetite, or hysterical antipathy to particular viands, to total and prolonged abstinence, as a symptom of delusion or delirium. In the insane, food has been consistently refused for years. During this time, the system was, of course (see FASTING), sustained by compulsory alimentation. The causes of such a course are generally local disease in the organs of digestion, creating disgust and loathing towards food, and associating suffering with the process of nourishment; the fear of death, or the desire for death. The motives assigned for such feelings or resolution vary, of course, as the morbid condition may affect the stomach or the brain; and, according to the mental state predominating, suicide may be courted, or poisoning, drugging, or pollution of aliment may be dreaded. The throat or bowels may be imagined to be hermetically sealed; God or Satan may have imposed abstinence; the body is dead, inanimate, or belongs to another.

Absurd as such principles of action may be, they prove inexpugnable to persuasion, or to the pangs of hunger and exhaustion, and require a special course of treatment. The determination may be exorcised by medicine; it may be overcome by commands, threats, bribes; it may be evaded by giving eggs, cocoanuts, milk from the cow, and other substances, into which mercury, arsenic, &c., cannot well be introduced; or it may be defeated by placing food in the stomach through the instrumentality of the stomach-pump. There have been epidemics of maniacal abstinence.—Chipley, *American Journal of Insanity*, July 1859; Browne, *Report Crichton Institution*, 1854.

SI''TTA. See NUT-HATCH.

S'IVA (a Sanscrit word, literally meaning happy, auspicious) is the name of the third god of the Hindu Trimûrti (q. v.) or triad, in which he represents the principle of destruction. The name S., as that of a deity, is unknown in the Vedic hymns, but established as such in the epic poems, *Purân'as* and *Tantras*. The worshipers of S. (see S'AIVAS) assigned to him the first place in the Trimûrti; and to them he is not only the chief deity but the deity which comprises in itself all other deities. Thus, in the *S'iva-Purân'a* (see PURAN'A), he is addressed as Brahma, Vishn'u, Indra, Varun'a, as the sun and the moon, as earth, fire, water, wind, &c.; but even in the Purân'as relating to Vishn'u, his power is exalted in praise, and he is addressed with the utmost awe. The symbol of S. is the *Linga* (q. v.), emblematic of creation, which follows destruction. From each of his numerous attributes or characteristics he derives a name or epithet. He has five heads (hence his name *Panchânana*, &c., the five-faced);

three eyes (hence his name, *Trinetra*, &c., the three-eyed), one of which is on his forehead, and indicates his power of contemplation; and in the middle of his forehead he wears a crescent.

His hair is clotted together, and brought over the head so as to project like a horn from the forehead. On his head he carries the Ganges, whose course he intercepted by his hair, when this river descended from heaven, so as to enable the earth to bear its fall (hence his name, *Gangâdhara*, &c., the Ganges-bearer). Round his neck he carries a garland of human skulls; and his throat is dark blue, from the poison which he swallowed when it emerged from the ocean, churned by the gods for the attainment of the beverage of immortality, and threatened to destroy the world. In his hands he holds the trident, a club or pole, armed at the upper end with transverse pieces, representing the breastbone and ribs adjoining, and surmounted by a skull and one or two human heads. His weapons are the *Khinkhira*, which is not described, a bow called *Ajakava*, or *Ajagava*, a thunderbolt, and an axe. As the destroyer of the world, he is also called *Kâla* (Time or Death), and represented as of black color. One of his representations is also half-male and half-female, emblematic of the indissoluble unity of the creative principle (hence his name, *Ardhanârîs'a*, the half-female-lord). He is clothed in a deer-skin; or he also holds a deer in one of his hands; or he sits on a tiger-skin, or is clothed in it. When riding, his vehicle is the bull Nandi, whom he also carries as an emblem in his banner. He resides on the wonderful mount Kailâsa, the northern peak of the Himalaya, where he also rules over the north-east quarter. His principal wife is *Durgâ* or *Umâ* (q. v.); his sons are GANES'A and KARTTIKEYA (q. v.). One of his principal attendants is *Tan'du*, who is one of the original teachers of the arts of dancing and mimicry, whence S. is the patron of the dancers, and is called *Nat'es'wara* (lord of the dancers). Besides Tan'du, a host of other attendants and companions, together with demons and other beings surrounding him, are named by the Purân'as.

Amongst the principal achievements of this god is his conflict with the god Brahma, who was originally possessed of five heads, but lost one through exciting the anger of S.; for the fifth head of Brahma once disrespectfully addressing S., and even challenging his power, S. immediately cut off the offending member with the nail of his left thumb. A similar penalty he inflicted on *Daksha*, his father-in-law, who once performed a great sacrifice, but neither invited his daughter Satî nor her husband Si'va. S., nevertheless, appeared at the sacrifice; but when Satî, offended at the reception she met with, threw herself into the sacrificial flames, S. cut off the head of Daksha; and Daksha would have remained headless, had not the gods interfered in his favor with S., who, out of compassion, replaced his head by that of a ram. Besides these feats, he killed several demons.—*Ruru, Andhaka, Tripura;* and he also reduced to ashes *Kâma* (the god of love), who, at the instigation of the gods, undertook to excite the desire of S. to procreate a son, but was indiscreet enough to choose for this purpose a time when S. was engaged in fierce austerities (see KAMA). S. is especially worshiped under the symbol of the Linga; but there are periods at which homage is paid to him also, under other forms, corresponding with the description given above. Hindu mythology knows, properly speaking, no incarnations of S. like those of Vishn'u; in some writings, however, some of his forms, especially that called Bhairava, and that called Virabhadra, are considered to be his sons or incarnations. S., like Vishn'u (q. v.), has a thousand names by which he is addressed; some derived from his exterior attributes have been mentioned before; among the rest, the principal are *Îsa* or *Is'wara* (lord); *Mahes'a* or *Mahes'wara* (the great lord); *S'ankara* (the conferrer of happiness); *Rudra* (the terrible), or *Mahârudra* (the very terrible); and *Mahâdeva* (the great god). For his worshipers, see S'AIVAS.

SI'VAS, a city of Asiatic Turkey, capital of the pashalic of the same name, is situated on the Kizil Irmak (anc. *Halys*), 60 miles south-south-east of Tokat. S. covers a large extent of ground, is well built, has numerous old mosques, khans, gardens, and excellent bazaars, manufactures coarse woollens, and carries on a considerable transit trade. Pop. 25,000, of whom about 5000 are Armenians, the rest Turks. S. is built on the site of the ancient *Sebasteia*, from which it derives its name.

SIVA'SH, or PUTRID SEA. See CRIMEA.

SIVATHE'RIUM (*Siva*, an Indian god; and Gr. *therion*, a wild beast), a remarkable genus of extinct mammals, found in the Miocene strata of the Sewalik Hills in Northern India. It had a large skull, nearly as long as that of an elephant, supported on a neck little short of that of a giraffe, but much stronger. The face was short, and the nasal bones were prolonged into a pointed arch above the external nostrils, indicating the existence of a trunk or proboscis, an organ unknown among the Ruminantia to which it belonged. Like the existing 4-horned antelope of India, it had two small diverging horns, rising from the brow between the orbits, and two large, probably palmated horns, further back. In general appearance, it resembled a huge antelope. The remains of two species have been described by Falconer and Cautley.

SIX ARTICLES, STATUTE OF, an enactment of the 33d year of Henry VIII., passed January 7, 1541, and commonly called the Bloody Statute. The object of this statute was to compel, from all the subjects of the crown, the uniform profession of certain doctrines, six in number, which are carefully recited in the act. These doctrines are (1), the Real Presence of Christ in the Eucharist, and Transubstantiation; (2), the sufficiency of communion in one kind only; (3), the unlawfulness of the marriage of priests; (4), the obligation of vows of chastity; (5), the propriety of retaining private masses; (6), the expediency and necessity of auricular confession. The penalties of this act exceeded in severity almost every precedent, at least in England, and they are specially severe against impugners of the first article, all of whom, whether they dispute, write, or preach against it, are to suffer death as heretics, with forfeiture of all their goods to the crown, and without being allowed to abjure the error. With regard to the remaining four articles; the usual penalty of felony is attached to the crime of publicly preaching against them; private impugners are liable for the first offence to imprisonment at the king's pleasure, for the second, to death; and the same, or nearly the same penalties are enacted against priests or nuns marrying or cohabiting, and against persons contemptuously refusing to confess at the prescribed times, or to receive the sacraments. The act at first was enforced with great severity, but it was somewhat mitigated in 1544, and was finally repealed in 1549.

SIXTUS, the name of five popes, of whom two call for particular notice, Sixtus IV. and Sixtus V. The former (originally named Francesco della Rovere), born July 22, 1414, was a native of a small village near Savona, and a member of a very humble family. He was a scholar of the celebrated Cardinal Bessarion, and became a member of the Franciscan order, in which capacity he obtained the highest reputation throughout Italy as a preacher. On the death of Paul II. in 1471, Rovere was elected to the Roman see. The domestic government of S. has been strongly condemned. His inordinate partiality to his relatives exhausted the papal treasury, and led to many questionable exactions, and to gross abuses in the dispensation of church patronage. His excessive facility, too, in dispensing favors, led to his not unfrequently conferring the same benefice on more than one individual. But the worst imputation upon the memory of his pontificate arises in connection with the political affairs of Florence, and especially with the conspiracy against the Medici family, known in history as the Pazzi conspiracy. In the last act of this nefarious plot, the murder of Giuliano in the church at Florence, S.'s nephew, Riasio, was present, and when, after its failure, the leaders, including the Archbishop of Pisa, were executed, S. excommunicated the Duke Lorenzo and all the magistrates of the city. Although this censure was passed professedly for the violation of the immunities of the church in putting an ecclesiastic to death, yet it has drawn upon S. the suspicion of complicity, or at least of connivance after the fact; and has led to much controversy among historians.

The necessities of defence against the Turkish invasion embarrassed still further the finances of the pope, and even the Catholic historians deplore the lengths to which ecclesiastical exactions and the simoniacal distribution of benefices were carried in the latter years of Sixtus. In many respects, nevertheless, his administration was liberal and public spirited. He did much to foster learning and to encourage art. Under him, the Vatican library continued to increase, and he contributed notably to the improvement and decoration of the city. In 1482 he entered into an alliance with the Venetians against the Duke of Ferrara, which led to a general Italian war, and ended in a dissolution of the Venetian alliance, so mortifying to the pope, that his death is said to have been caused by chagrin and mortification, August 13, 1484. —SIXTUS V., in many respects, one of the most remarkable of the modern occupants of the Roman see, originally named Felice Peretti, was born (December 13, 1521) near Montalto, of parents so poor, that his boyhood was spent in the humble occupation of a swineherd. While thus engaged, the boy attracted the notice of a conventual Franciscan father, who procured his admission into the order. He was ordained priest in 1545, and became professor of theology at Siena. His reputation as a preacher led to his being transferred to Rome, where he rose to its first dignities. He accompanied Cardinal Buoncompagno as theologian in his legative mission to Spain (1565); and on the accession of Pius V. to the pontificate, was named cardinal (1570). On the accession of his former patron, Buoncompagno, under the name of Gregory XIII., Cardinal Montalto might have exercised the highest influence, but he lived a retired and mortified life, and was believed to have fallen almost into the decrepitude of age and infirmity.

This appearance was afterwards ascribed by his enemies to the design of concealing his ambitious views; and there is a well-known but apocryphal story of his having, when elected pope on

the death of Gregory in 1585 (April 24), flung aside his crutch, and revealed himself to the astonished cardinals in the full vigor of his physical strength and his moral character. His pontificate, however, was a most active and energetic one, and was marked by vigorous measures of improvement in every department of administration, ecclesiastical as well as civil. His first care was to repress the prevailing license and disorder of the city of Rome, and of the papal states generally, by effectually breaking up and exterminating the lawless bands of outlaws by which both were infested. His administration, both in this matter and in the repression of immorality, was rigorous perhaps to the extreme of cruelty; but the evil was one which seemed to call for extreme remedies. He reformed the administration of the law, and the disposal of public patronage; and he entered upon numerous and most comprehensive projects for the moral and material improvement of Rome. Many of his great works are still recognizable at Rome under his name, and are popularly remembered as his; among which are the library buildings of the Vatican. A distinguishing characteristic of his administration, too, was its disinterestedness. He steadfastly refused to use his position for the purpose of advancing any of his relatives, or to bestow upon them property or money derived from the public; and by judicious retrenchment he secured within the first years of his short pontificate a surplus of above 5,000,000 of crowns.

It is of course impossible to enter into the details of his foreign policy; it will be enough to say that its great aim was, in the strongest sense of the words, to advance the cause of the Roman Catholic Church in every portion of Christendom, against the Huguenots in France, against the Lutherans in Germany, and against Queen Elizabeth in England. At the same time, he entertained a deep jealousy and apprehension of the designs of Spain; and he resisted persistently the excessively rigorous measures of the Spanish Inquisition as organized under Philip II. His church administration was equally vigorous and energetic. He fixed the number of the Sacred College of Cardinals at 70; and it was under him that the present organization of separate congregations of cardinals for the several departments received some of its most important developments. He published a new edition of the Septuagint, and an edition of the Vulgate, which has become famous from the multiplicity of its errors, subsequently corrected in the edition of Clement VIII. Many of the popular stories regarding him are derived from Gregorio Lete's *Vita di Sisto V.* (2 vols., Lausanne, 1669), a work of no authority. See also Tempesti, *Storia della Vita e Gesti de Sisto V.* (2 vols., Rome, 1754); Lorentz, *Sixtus V. und seine Zeit* (Mainz, 1852); Ranke, *Fürste und Völker von Süd-Europa,* and Von Hübner, *Sixtus V.* (1874).

SI'ZAR (from *size*, in university slang, an allowance of victuals from the buttery—or the smallest quantity of anything which can be bought, a word derived from *assize*, formerly the same as *assess*, to apportion), a name given to an order of students at Cambridge and Dublin universities, who are admitted on easier terms than others. Duties of a somewhat menial kind were originally required to be performed by the sizars, but these have long since gone into disuse. Sizars are not on the foundation, and therefore so long as they remain such, are not eligible for fellowships; but they may at any time become pensioners, and generally sit for scholarships immediately before taking their first degree. If successful, they are on the foundation, and may become candidates for fellowships when they have taken their degree.—At Oxford, there is a similar order of students, denominated Servitors.

SIZE. See GLUE and GELATINE.

SKA'GEN, CAPE, or THE SKAW, the most northerly point of Jutland, Denmark. On it is built a light-house of stone, 67 feet high, the lat. of which is 57° 43′ 8″ N., long. 10° 36′ 5″ E.; and near it is a small town of 1400 inhabitants.

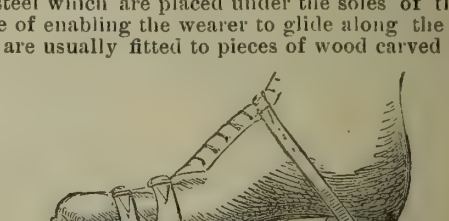
SKA'GER-RACK (' Crooked Strait of Skagen; ' *rack* is probably from the same root as A.-S. *raca*, Ger. *rachen*, throat; thus being equivalent to the Celtic *Kyle* [in Kyles of Bute], Lat. *gula*, English *gully*—is the *Race* of Alderney allied to *Rack?*), an arm of the North Sea (q. v.) lying between Denmark and Norway, and communicating with the Cattegat, is about 150 miles long from west-south-west to east-north-east, and 80 miles broad. The depth is much greater on the Norwegian than on the Danish coast, being on the former about 200 fathoms, while on the latter it varies from 30 to 40 fathoms, increasing towards the center to about 60. When free from violent storms—to which, however, it is very subject—the current runs east on the side next Denmark, and west on that next Norway, the harbors being all on the latter coast.

SKALD (allied to *skill;* the radical sense is, to separate, and hence to discern) signifies, in old Norse, a poet. The name was given specially to that class of poets who exercised their art (*Skálldskapr*) as a vocation requiring a learned education; that is, a knowledge of the construction of verse, and of the enigmatical imagery, roughly shaped out of obscure tradition, to which Scandinavian poets were prone. The great, if not the only aim of the Skaldic poetry was to celebrate the deeds of living warriors or of their ancestors. For this reason, princes attached Skalds to their courts, and competed with each other, by magnificent presents, for the possession of the most skilful minstrels. Very few complete Skaldic poems are extant; but, on the other hand, the multitude of fragments preserved, partly in the younger Edda (q. v.), partly in the Sagas (q. v.), and the Heimskringla (q. v.), is very great. A manuscript of the younger Edda, belonging to the university of Upsala (which has been printed in the *Historia Literaria Islandica* of Einarsen), contains a list of the most celebrated Icelandic and Norwegian Skalds of the 13th c., under the name of *Skálldatal.* The songs relating to the religious and heroic traditions of the North, which are found in the Edda, go back to an earlier time, in which the class or school of ' Skalds,' properly so called, did not yet exist. The authorship of these primitive Eddaic songs is unknown; but they are the sources from which the ' Skalds ' of later times drew much of their inspiration.

SKA'LITZ, or SZAKO'LCZA, a town in the north-west of Hungary, near the borders of Moravia, 47 miles N. of Presburg, on the left bank of the March, with a pop. (1880) of 5715. It is nearly in the form of a square, is surrounded by walls, has several Protestant and Roman Catholic churches, a Franciscan monastery, town-hall, &c., besides large manufactures of cloth. Good wine is produced in the vicinity, and hemp is largely grown.

SKATE, the popular name of several species of Ray (q. v.).—The COMMON S. (*Raia batis*), known in Scotland as the *Blue S.* or *Gray S.*, and in the south of England as the *Tinker*, is plentiful on most parts of the British coasts; the breadth of the body is to its length in the proportion of about four to three; the snout sharp; a slight concavity in the outline between the snout and the extreme lateral angle of the pectoral fin; a short hard tubercle in front of each eye, and another on the inner side of each; a single row of spines commencing on the dorsal ridge near the origin of the ventral fins, and reaching along the tail as far as the first of the two small fins which it bears; the upper parts grayish brown, the belly dusky white with darker lines. It attains a large size, having been known to weigh 200 lbs.—The LONG-NOSED S. (*R. rostrata* or *mucronata*) is remarkable for the elongation and sharpness of the snout. The upper surface is of a light lead color, the lower grayish white. The tail has a row of crooked spines. This species is not uncommon on the British coasts, and attains a large size.—The SHARP-NOSED S. (*R. oxyrhynchus*) has also a very sharp snout, but less elongated. It is thicker in proportion to its other dimensions than any of the other British species, and attains a very great weight. The line of the body from the snout to the extreme lateral expansion is waved. The tail is armed with three rows of spines. The upper surface is of a brown color; the color being lighter than in the other species, this is generally known in Scotland as the *White Skate.*—The FLAPPER S. (*R. intermedia*) is very thin and broad; it has only a line of pointed tubercles on the tail; the upper surface is dark olive green, with numerous white spots. Skates are very voracious. They are often caught by lines, but the greater number of those brought to market are caught by trawl-nets. They are much esteemed for food in most countries, yet on some parts of the British coast they were until recently rejected as worthless.

SKATES AND SKATING. Skates are small keels or blades of iron or steel which are placed under the soles of the feet for the purpose of enabling the wearer to glide along the surface of ice. They are usually fitted to pieces of wood carved into some-



Skate attached to the Foot.

what of a boat-like form, to which straps of leather are adjusted, to enable the skater to attach them firmly to his feet. Of late, in some improved skates, the wood has given way to metallic fittings, which are neater and perhaps preferable; they are, however, liable to rust, and consequently to get out of order. In Britain, skating is a favorite pastime in winter; and in England, and Scotland especially, is carried to a degree of excellence not known in other countries: the skaters study the most graceful curves, and the nicest possible balancing of the body, when going

at great speed. In such countries as Holland and the more northern parts of Europe, skating is used merely as a necessary means of locomotion among the laboring classes.—The name of *roller-skate* has been adopted for a frame for the foot, fitted on small wheels or rollers. On a specially prepared surface, such as an asphalted floor, these roller-skates permit a smooth, gliding motion somewhat analogous to that of skating. Places for this amusement (called *rinking*) have of late years sprung up all over the country, and are known as *skating-rinks*.

SKE'LETON (Gr. *skeletos*, dry) is the term applied in anatomy to designate the hard parts or framework of animals. In the invertebrate animals, the skeleton, except in the case of certain corals, is tegumentary or dermal, forming the outer hard and protective covering, as in the *Echinodermata*, *Mollusca*, and *Crustacea;* and like the epirdermis and its appendages, is non-vascular, and can only be increased by additions to its edges. This hard insensible covering serves to protect the animal from hurtful external influences, and to afford fixed points of attachment to the muscles which move the body and limbs; the muscles, however, always lying interior to the skeleton, and not clothing it, as we see in the vertebrata. We scarcely ever observe, amongst the invertebrata, that the skeleton bears any definite relation to the nervous system, which is merely protected by it to the same extent as the other soft tissues. Moreover, in none of these animals are the hard parts composed of true bone.

In the vertebrate animals, although we find occasional cases of bone being deposited in various parts of the body, its most constant position is around the central masses of the nervous and vascular systems, with rays extending thence into the middle of chief muscular masses, forming the bases of the limbs. 'Portions of bone are also developed, to protect and otherwise subserve the organs of the senses, and in some species are found encasing mucus-ducts, and buried in the substance of certain viscera—as, e. g., the heart in the bullock and some other large quadrupeds. Strong membranes, called "aponeurotic," and certain leaders or tendons, become bony in some animals—as, e. g., the "tentorium" in the cat, the temporal fascia in the turtle, the leaders in the leg-muscles in the turkey, the nuchal ligament in the mole, and certain tendons in the abdominal muscles of the kangaroo, which, so ossified, are called the marsupial bones.'—Owen's *Structure of the Skeleton*, p. 163. In some animals (e. g., the sturgeon, the crocodile, the armadillo), bony matter accumulates upon or near to the surface of the body, rendering the skin in some cases absolutely ball-proof.

The following is Owen's theory of the vertebrate skeleton (which, however, is not supported by embryological research—see end of article). The superficial or skin bones constitute the 'dermo-skeleton' (Gr. *derma*, skin); the deep-seated bones in relation to the nervous axis and locomotion, form the 'neuro-skeleton' (Gr. *neuron*, nerve); the bones connected with the sense-organs and viscera form the 'splanchno-skeleton' (Gr. *splanchnon*, a viscus or inward part); while those developed in tendons, ligaments, and aponeuroses are termed the 'sclero-skeleton' (Gr. *skleros*, hard). In the arrangement of the various parts of the dermo-, splanchno-, and sclero-skeletons, no definite plan or law can be detected. The definite end or purpose gained by the position of the bony plates, cases, or rods, belonging to these skeletons, is usually easily seen to be connected with the habits and well-being of the animals in which they occur, but the parts cannot be referred to one general type, as in the case of the neuro-skeleton. We will follow Professor Owen in taking the sturgeon and armadillo as examples of a dermo-skeleton, and shall condense the remarks which he makes on their outer covering. The head of the sturgeon is defended by a case of superficial bony plates, and the body by five longitudinal rows of similar plates, one extending along the mid-line of the back, one along each side of the body, and two along the belly, between the ventral and pectoral fins. These fishes habitually swim low and grovel along the bottom, turning up the mud and sand with their pig-like snout, and feeding on the decomposing organic substances carried down by strong and rapid currents. The heavy dermal osseous plates, regularly arranged in orderly rows along the middle and sides of the body, act as well-arranged ballast. The protection which their plate-armor affords them against the logs and stones hurried along their feeding-grounds, renders needless the ossification of the immediate case of the brain and spinal marrow, and, consequently, all the parts of the neuro-skeleton remain in the flexible, elastic, gristly state common to all the so-called cartilaginous fishes; the weight of the dermo-skeleton requiring that the neuro-skeleton shall be as light as possible, consistently with the defensive and sustaining functions which it is called to perform.

The coat of mail in which the ganoid fishes of an early period were clothed, was probably subservient to the same ends as the dermal plates of the sturgeon; and in most of these fishes, as in the sturgeon, the dermal bones are coated externally with a very hard material resembling enamel. In these extinct fishes, the plates are more close-set than in the sturgeon, overlapping each other, and being fastened together like tiles by a peg of one entering a socket in the next, and conversely.

In the armadillo, the dermal bones are small, usually five or six sided, smooth internally, and variously sculptured externally—the pattern, however, being constant in, and characteristic of, each species. They are united together at their margins by rough surfaces, and collectively resemble a tesselated pavement. To allow of the requisite movements of the trunk of the armadillos, which have the power of rolling themselves into a ball, a certain number

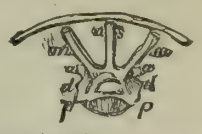


Fig. 1.—Transverse section, showing portions of Dermo- and Neuro-skeleton of Armadillo.
(The signification of the letters is subsequently given.)

of transverse rows, marked in the figure, are interposed, having an elastic yielding attachment with one another, and with the anterior and posterior fixed parts of the trunk-armor; and by this arrangement, the head and limbs can be withdrawn beneath the central case, by the action of strong subcutaneous muscles. In the colossal extinct armadillo (the *Glyptodon*), the trunk-armor was not divided by bands, but was composed of one immovable piece, covering the back and sides—an arrangement by which the dermo-skeleton would afford increased protection against falling timber, the attacks of other animals, &c.

The splanchno-skeleton is at first sight less apparent than the dermo-skeleton. In most air breathing vertebrates, the larynx, trachea, and bronchial tubes contain a cartilaginous framework, which sometimes becomes ossified; in fishes, and in the batrachians in the tadpole state, the gills are supported upon a cartilaginous or osseous framework, developed independently of the vertebral skeleton; and in mammals, the heart contains a bone that serves as a support for its muscular and ligamentous fibres. If to these parts we add the so-called 'sense-capsules'—the bony cap which is found in the outer coat of the eye in many birds and most fishes; the hard bony envelope which surrounds the internal ear, and which subsequently, as the petrous portion of the temporal bone, becomes incorporated in most vertebrates with the neuro-skeleton; and the turbinate bones of the nose—and the teeth, we have the principal parts of the splanchno-skeleton. The sclero-skeleton requires no further explanation than that which has been already given; and we therefore proceed to what may be called the skeleton proper—the neuro-skeleton.

From the nature of the subject, it is impossible to avoid the introduction of a considerable number of technical terms, which will probably be new, and will sound somewhat harshly to many of our readers; and as few writers can popularize a difficult subject more successfully than Professor Owen himself (unquestionably the greatest osteologist of the present age) we shall for the most part follow the history of the neuro-skeleton which he drew up for the benefit of general readers in *The Circle of the Sciences*. A thoughtful examination of the skeleton of any vertebrate shows that it is arranged in a series of segments, following and articulating with each other in the direction of the axis of the body, from before backwards in brutes, from above downwards in man.

Each complete segment, called a 'vertebra,' consists of a series of osseous pieces arranged according to the plan shown in figs. 2 and 3, so as to form a bony hoop or arch above a central piece, for the protection of a segment of the nervous axis; and a bony hoop or arch beneath the central piece, for the protection of a segment of the vascular system. The upper hoop, N, is called the 'neural arch' (Gr. *neuron*, a nerve), and the lower hoop, H, the 'hæmal arch' (Gr. *hæma*, blood); while their common center, C, is termed the centrum. The neural arch is formed by a pair of bones, *n*, *n*, called 'neurapophyses' (Gr. *apophysis*, a projecting part or process), and by a bone, *ns*, sometimes cleft or bifid, called the 'neural spine;' it also sometimes includes a pair of bones, *d*, *d*, called 'diapophyses' (Gr. *dia*, across). The hæmal arch is formed by a pair of bones, *pl*, called 'pleurapophyses' (Gr. *pleuron*, a rib); by a second pair, *h*, called 'hæmapophyses;' and by a bone, *hs*, sometimes bifid, called the 'hæmal spine.' It also sometimes includes parts or bones called 'parapophyses' (Gr. *para*, transverse). Bones, moreover, are developed, which diverge as rays from one or more parts of a vertebra. Professor Owen divides the various parts of a vertebra into (1) the autogenous and (2) the exogenous parts. The autogenous parts are those which are developed from independent centers of Ossification (q. v.), and are termed the elements of the vertebra; while the exogenous parts are those that grow from parts previously ossified, and are termed processes. The line between these two sets of parts cannot be strictly drawn, since parts which are usually exogenous are sometimes autogenous, and *vice versâ*.

The autogenous parts or elements are the centrum, C; the neurapophyses, *n, n;* the neural spine, *ns;* the pleurapophyses, *pl, pl;* the hæmapophyses, *h, h,* and the hæmal spine, *hs;* while the exogenous parts or processes are the diapophyses (fig. 3), *d, d;* the parapophyses (fig. 5), *p, p;* the zygapophyses (fig. 3), *z, z* (Gr. *zygos*, a junction); the anapophyses (fig. 1), *a, a* (Gr. *ana*, backwards); the metapophyses (fig. 1), *m, m* (Gr. *meta*, between); the hypapophysis (fig. 5), *y* (Gr. *hypo*, below); and the epapophysis (fig. 2), *e* (Gr. *epi*, upon). These individual parts may be united with each other in various ways, and may occur in various degrees of development; sometimes they (or some of them) remain entirely disjoined even in the adult animal, while in other cases they are united into a single piece, so that their real distinctness can only be recognized by tracing the history of their development. In most instances, some one or more of these parts will be found to be altogether deficient, while in other cases one set of parts is exaggerated to a great degree.

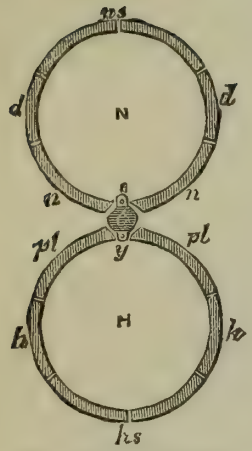

Fig. 2.—Typical Vertebra (ideal.)
(The signification of the letters is fully given in the text.)

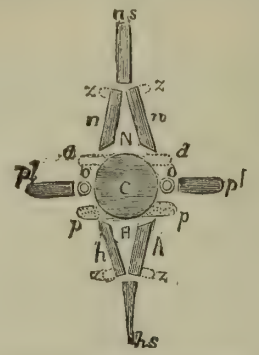

Fig. 3.—Another Modification of a Typical Vertebra:
C, the centrum, giving off *d, d,* the diapophyses, and *p, p,* the parapophyses; the neural arch N, enclosing the spinal cord, is formed by *n, n,* the neurapophyses, and *ns,* the neural spine; the hæmal arch H, enclosing the great centers of the circulation is formed by *h, h,* the hæmapophyses, and *hs,* the hæmal spine. From both the neurapophyses and the hæmapophyses may be given off the zygapophyses, *z, z.* The lateral arches which may enclose the vertebral arteries, O, O, are completed by the pleurapophyses, *pl.*

Thus, in fig. 4, which exhibits the third or parietal segment of the human skeleton, the neural arch, N, is much expanded, while the hæmal one, H, is contracted; while more commonly, as is shown in fig. 5, which represents a thoracic segment or vertebra of a raven, the hæmal arch, H, is much expanded, and the neural one, N, contracted; while sometimes, again, as in the tail of the crocodile and of many other animals, both neural and hæmal arches are simultaneously contracted. The segments are commonly simplified, and made smaller as they approach the end of the vertebral column or axis, one element or process after another being removed until the vertebra is reduced to its centrum, as in the diagram of the archetype vertebral skeleton. If we glance at the typical vertebra represented in fig. 3, we observe the diapophyses projecting above a canal that serves for the passage of a blood-vessel, and parapophyses which form the lower boundaries of this canal. These elements never attain any high development in mammals, birds, or reptiles; thus, in the human cervical vertebra, they form the two roots of the transverse process surrounding the foramen for the passage of the vertebral artery, while in the thoracic vertebra of the bird (see fig. 5) the diapophyses, *d, d,* form the transverse processes, and the parapophyses, *p, p,* reduced to mere rudiments, form the articular surfaces with which the heads of the ribs come in contact.

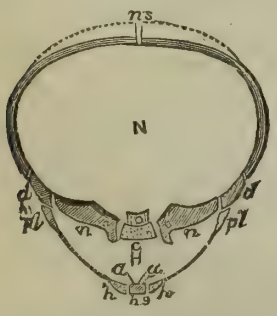

Fig. 4.—Parietal, or Third Segment or Vertebra of the Human Skeleton.
(Letters as in preceding diagrams.)

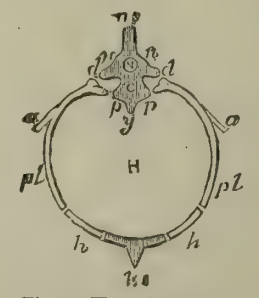

Fig. 5.—Thoracic Segment or Vertebra of a Raven.
(In this and the preceding figure, *a, a,* are diverging appendages.)

In fishes, however, they are much developed, and in the cod tribe are even larger and broader than the pleurapophyses or true ribs. The ordinary function of these lateral processes is to afford attachment to muscles, to protect the lateral vascular trunks (as in the case of the vertebral artery), and to give support to the pleurapophyses, *pl, pl,* whose development varies extremely in different parts of the same vertebral column, as well as in different animals. Then, in the human cervical vertebra (fig. 6), they form the short bifid transverse processes which are anchylosed at their base to the diapophyses and parapophyses which surround the vertebral canal. In the thoracic segments (fig. 5), they are developed separately, and constitute the ribs which form the greater part of the circumference of the hæmal arch. Proceeding to the consideration of the parts below the centrum, we often find the entire hæmal arch wanting, as in the cervical and lumbar vertebræ of man and mammals; but in the tail of some mammals and of reptiles, a hæmal arch, protecting the caudal artery and vein, and closely resembling a neural arch, is found. It is in the thoracic region of mammals, birds, and reptiles that we find the greatest expansion of the hæmal arch (see fig. 5); the hæmapophyses here articulating with the extremities of the ribs instead of with the centrum, and the arch surrounding the entire visceral cavity. In man and mammals, the hæmapophyses remain unossified, and are known as the cartilages of the ribs; but in birds and reptiles, they are ossified, and constitute the sternal ribs. The hæmal spine, *hs,* presents great variety of form, and is often altogether absent. In the mammalian thorax, it occurs as a flat sternum; in birds, the flatness is replaced by a prominent keel on the mesial line, so that a transverse section almost resembles a neural spine; while in reptiles, again, the hæmal spine or sternum is flattened laterally, as in mammals.

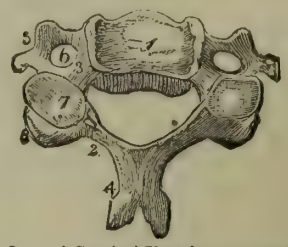

Fig. 6.—A Central Cervical Vertebra as seen from above:
1, the body; 2, the lamina; 3, the pedicle; 4, the bifid spinous process; 6, the vertebral foramen; 7, the superior articular process. This figure, as compared with the preceding ones, must be regarded as inverted, the neural arch being here below the centrum.

The hæmapophyses and hæmal spine are absent in the abdominal region of mammals and birds, but are continued backwards in the saurians or lizard like reptiles, whose hæmal arch is, notwithstanding, incomplete, from the absence of pleurapophyses. In serpents, the hæmal arches are wanting through the whole trunk, the ends of the ribs being free; and in fishes generally, the hæmapophyses and hæmal spine are absent, or unossified.

Having noticed, as fully as our space permits, the modifications which the typical vertebra undergoes in various animals, and in different parts of the same animal, we now come to the more difficult subject of 'the archetype vertebrate skeleton,' which is made up of a series of vertebræ arranged in a continuous row. The accompanying scheme or diagram represents Professor Owen's conception of the common pattern or archetype of the vertebrate skeleton. It is difficult at first sight to see any resemblance between this figure and the human skeleton; but, in fact, the human skeleton, of all others, recedes the furthest from the common pattern; and if we turn to fishes, which were the first form of vertebrate life introduced into this planet, we find that they deviate the least from the archetypal idea. If proof be demanded that a given bone in the human skull is an element of a particular vertebra, it is afforded by tracing the same bone through its various modifications in mammals, birds, reptiles, and fishes, till the simple archetypal form is arrived at. The skull is found to be but a continuation of the backbone, and to consist of four vertebræ or segments, corresponding to the four consecutive enlargements of the nervous system which we call the brain. These segments, reckoning them from behind forwards, are termed the occipital, the parietal, the frontal, and the nasal segment. Each segment consists of a neural and a hæmal arch.

The Neural Arches are :

N. I. Epencephalic Arch (bones Nos. 1, 2, 3, 4 in figure). N. II. Mesencephalic Arch (bones Nos. 5, 6, 7, 8 in figure). N. III. Prosencephalic Arch (bones Nos. 9, 10, 11, 12 in figure). N. IV. Rhinencephalic Arch (bones Nos. 13, 14, 15 in figure).

The Hæmal Arches are :

H. I. Scapular Arch (Nos. 50—52). H. II. Hyoidean Arch (Nos. 38—43). H. III. Mandibular Arch (Nos. 28—32). H. IV. Maxillary Arch (Nos. 20—22).

The special names given by Owen to the various elements of that hæmal arch, from above downwards, are 'suprascapular,' No. 50; 'scapula,' No. 51; 'coracoid,' No. 52. The scapular arch thus formed supports and protects the heart or center of the hæmal system, and in most fishes supports the pectoral fin, while in other animals the appendage that here becomes a fin is modified into a fore-leg, a wing, an arm, and a hand. Some of the special names originally employed in human anatomy are retained and applied to like parts in the pectoral fin of the fish; but it will be

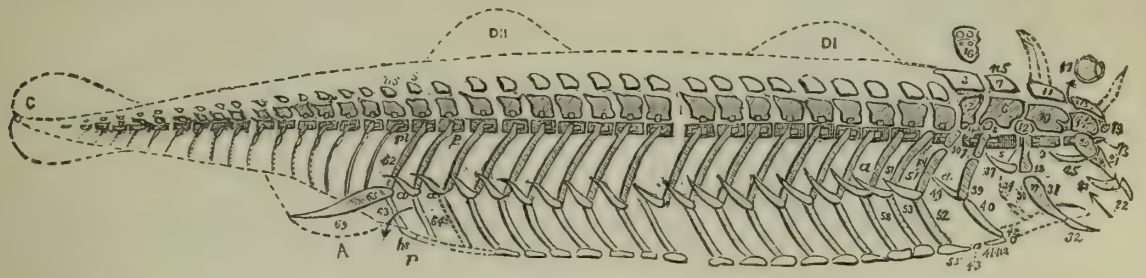

Fig. 7.—Diagram of Archetype Vertebrate Skeleton, composed of the following parts:

1, Basioccipital; 2, Exoccipital; 3, Supraoccipital; 4, Paroccipital, constituting the neural arch of the first or occipital vertebra of the head (the epencephalic arch); 5, Basisphenoid; 6, Alisphenoid; 7, Parietal; 8, Mastoid, constituting the neural arch of the second or parietal vertebra (the mesencephalic arch); 9, Presphenoid; 10, Orbitosphenoid; 11, Frontal; 12, Post-frontal, constituting the neural arch of the third or frontal vertebra (the prosencephalic arch); 13, Vomer; 14, Prefontals; 15, Nasal, constituting the neural arch of the fourth or nasal vertebra (the rhinencephalic arch); 16, Petrosal or acoustic sense-capsule; 17, Sclerotic, or ophthalmic sense-capsule; 19, Ethmoturbinal or olfactive sense-capsule;—20, Palatine; 21, Maxillary; 22, Premaxillary, constituting the maxillary hæmal arch; 25, 27, being its diverging appendages;—28, Tympanic; 29—32, Mandibular, or lower jaw, constituting the mandibular hæmal arch; 34, 37, Operculars, being the diverging appendages of this arch;—38, Stylohyal; 39, Epihyal; 40, Ceratohyal; 41, Basihyal; 42, Glossohyal; 43, Urohyal, constituting the hyoidean hæmal arch; 44, Branchiostegal, being its diverging appendages; 50, Supra-scapula; 51, Scapula; 52, Coracoid; 52', Episternum; 53, Anterior member, constituting the scapular hæmal arch, with its diverging appendages; 58, Clavicle;—62, Ilium; 63, Ischium; 64, Pubis, th : hæmapophysis of one of the lumbar vertebræ; 65, 69, Posterior extremity, constituting the hæmal arch of the sacral vertebra skeleton, with its diverging appendages.

The jaws are the modified hæmal arches of the first two segments; and the mouth opens at the interspace between these arches. The position of the vent varies (in fishes), but always opens behind the pelvic arch, S 62, 63, *p*, where this is ossified. Outlines of the chief ossified developments of the dermo-skeleton, in different vertebrates, are added by Professor Owen to the neuro-skeletal archetype; as, for example, the median horn, supported by the nasal spine, 15, in the rhinoceros; the pair of lateral horns developed from the frontal spine, 11, in most ruminants; the median folds, DI, DII, above the neural spines, one or more in number, constituting the dorsal fin or fins in fishes and cetaceans, and the dorsal hump or humps in the buffaloes and camels; similar folds are sometimes developed at the end of the tail, constituting the caudal fin, C, and the anal fin or fins, A, of fishes.

It has been already remarked, that bones which diverge as rays are formed from one or more parts of a vertebra. These 'diverging appendages' are mainly connected with the hæmal arches, and those which especially concern us are the pectoral appendages of the scapular arch, which become developed into fore-limbs or arms (54—57, fig. 9), and the pelvic appendages which are attached to their supporting hæmal arch, 63, *hs*. If we examine the skull

Fig. 8.

1, neural spines	A, nasal vertebra.
2, diapophyses of the three posterior vertebræ.	B, frontal vertebra.
	C, parietal vertebra.
3, neurapophyses.	D, occipital vertebra.
4, pleurapophyses.	E, supra-scapula.
5, hæmapophyses.	F, scapula.
6, hæmal spine.	G, ulna.
7, appendage proceeding from the pleurapophysis of the first arch to that of the second, and corresponding to internal pterygoid plate in man.	H, carpus.
	I, radius.
	K, metacarpus.
	L, phalanges.
	M, scapular arch.
8, centra.	N, hyoidean arch.
	O, inferior maxillary arch.
	P, superior maxillary arch.

of a cod-fish, in which the bones have been arranged according to the segments or vertebræ to which they belong, we observe that the occipital vertebra has a widely expanded hæmal arch, consisting of three pairs of bones with diverging appendages.

observed that Professor Owen designates each bone not only by a name but by a numeral. Of the two flat bones connecting the fin with the coracoid, the upper one is the 'ulna,' No. 54; the lower one, the 'radius,' No. 55; the row of short bones joined with these are the 'carpals,' No. 56; beyond which are the metacarpals and phalanges. Ascending from fishes to reptiles, we find that, in the lower batrachia (as the *amphiuma*), the scapulæ are detached from the occiput, and that other important modifications have occurred. The coracoids, *h* 52, are well expanded, three segments of the diverging appendage, *a*, are ossified, and two of these segments are bifid, showing a simple beginning of the radiating multiplication of parts. The first segment is the seat of these modifications, which have acquired for it the special name of 'humerus,' 53; the two divisions of the next segment of the appendage are called 'ulnar,' 54, and 'radius,' 55; the gristly mass, 56, is the carpus, and the two bony divisions are the digits or fingers, 57.

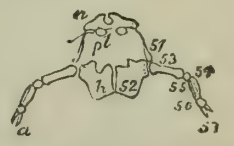

Fig. 9.—Posterior View of the Occipital Vertebra of *Amphiuma*:

n, neurapophyses; *pl*, 51, pleurapophyses of occipital vertebra or scapula; *h*, 52, hæmapophyses of occipital vertebra, or caracoid bone; *a*, 53—57, diverging appendages of occipital vertebra, or anterior limbs.

We have here got so distinct a rudimentary arm, separated from the head, although, according to the views propounded in this article, an appendage of the occipital segment of the cranium, that it is unnecessary to trace the further modifications that ensue, which lead finally to the arm and hand of man. It is only necessary to remark, that in mammals, except amongst the non-placental orders, the coracoid bone is reduced to a mere rudiment, being known as a process of the scapula, and that its function—namely, that of keeping the shoulders apart—is performed by the clavicle, which, according to Owen, is the hæmapophysis (58) of the first cervical vertebra (see fig. 7). With regard to the pelvic arch, we have only space to add that it must be regarded as the hæmal arch of one or more of the pelvic vertebræ; and there is undoubted evidence to show that the pelvic and scapular arches are constructed on the same plan; the 'ileum' answering to the scapula.

The elaborate and ingenious morphological theory of the skeleton here outlined was founded entirely upon the comparison of adult structures, and has of late years been entirely disproved, in principle and detail, by actual observation of the phenomena of development. For some account of the embryological theory of the skeleton, which is now securely founded, chiefly through the labors of Huxley, Parker, and Gegenbaur, see the article SKULL.

or Huxley's *Anat. of Verteb. Animals;* Balfour's *Embryology*, vol. ii.; or Parker's *Morphology of the Skull.*

SKE'LLIGS, THE, three rocky islands on the west coast of Ireland, about 8 miles west of Bolus Head, county Kerry, in long. 10° 32′ W. The lights on the Great Skellig are the first visible to ships crossing the Atlantic.

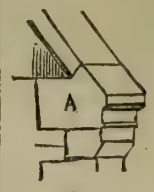
SKELTON, JOHN, an early English satirical poet, is supposed to have been born about the year 1460, but whether in Norfolk or Cumberland, is uncertain. He studied at both Cambridge and Oxford, and received from each the academical honor of laureate. His sovereign, Henry VII., appointed him tutor to the young Prince Henry, afterwards King Henry VIII.; and Erasmus, in allusion to his learning, styled him the light and grace of British scholars. At this time, S. had produced some translations, written elegies on Edward IV. (1483) and the Duke of Northumberland (1489), and was author of some stiff court masques and allegorical poems of little or no merit. He entered the church in 1498, and became rector of Diss in Norfolk, shortly after which he seems to have struck into that vein of original vernacular poetry, addressed to the multitude, for which he is unique among our elder bards, and which helped to fix our language. It consists in a flow of rattling voluble verse, unrestrained satire and jocularity, and a profusion of grotesque imagery mixed up with Latin and slang phrases. At times, S. has gleams of bright fancy and snatches of pleasant description. Of this higher class is his *Philip Sparrow*, being a poetical lamentation made by a young maiden (whose charms the poet describes with great gusto and minuteness) over the loss of a pet bird slain in a convent of black nuns at Carowe near Norwich.

The most humorous of his pictures of low life—often coarse enough—are found in the piece entitled *The Tunning* [or Brewing] *of Elynor Rummyng*, an alewife at Leatherhead in Surrey. This poem was highly popular, and was often reprinted in black-letter, garnished with a rude woodcut representation of the fat hostess. His best satires are *Colin Clout*, and *Why come ye not to Court?* The former is a general satire on the clergy; and the latter, a virulent attack on Cardinal Wolsey, whom the unscrupulous poet had previously flattered, but who had disappointed him of a prebend which he coveted. In this scurrilous lampoon, Wolsey is not only charged with arrogance, avariciousness, and incontinence, but is reminded of his 'base original' and 'greasy genealogy,' having been 'cast out of a butcher's stall.' The enraged cardinal ordered his libeller to be arrested, but S. took refuge in the sanctuary at Westminster, and received the protection of Abbot Islip. From this retreat he did not dare to emerge, but continued silent under its sacred shelter till his death in 1529. The 'pithy, pleasaunt, and profitable workes of Maister Skelton, Poete Laureate,' were collected and published in 1568, and reprinted in 1736. An edition, carefully edited by the Rev. A. Dyce, was issued in 1843, in 2 vols. 8vo.

SKE'RRIES, THE (Skerry is a term for any isolated sea-grit rock), small islands about 2 miles off the north-west coast of Anglesey, having a light-house 117 feet high. See also PENTLAND FIRTH.

SKE'RRYVORE is the chief rock of a reef which lies about 10 miles south-south-west of the south-west point of the island of Tiree (q. v.), and 24 miles west of Iona. This reef, which stretches from 8 to 10 miles in a west-south-west direction, is composed of compact gneiss, worn smooth by the constant action of the waves, and was long a terror to mariners, having caused the loss of one ship annually for forty years previous to 1844. The Northern Light-house Commission had long intended the erection of a light-house on S., the only point of this dangerous reef which could afford the needful foundation; but the difficulty of landing on the rock, from the immense force (three tons to the superficial foot) with which the Atlantic waves beat upon it, caused the delay of the scheme till 1834, when preparations were made in earnest. The design and superintendence of the construction of the building were intrusted to Mr. Alan Stevenson, who commenced operations on the rock in 1838, following generally the mode adopted by his father, Mr. Robert Stevenson (q. v.), in the construction of the Bell Rock (q. v.) Light-house, and in spite of occasional disasters from tempests, completed his work in 1844. The light-house is 138½ feet high; at the base 42 feet, and at the top 16 feet in diameter. The light, a revolving one, is produced by the revolution of eight large annular lenses round a lamp of four wicks, according to Fresnel's first dioptric system, and can be seen at a distance of 18 miles. The cost of erection was close upon £87.000. S. Light-house is nearly ⅛ths higher than that on the Bell Rock, and more than twice as high as the Eddystone. A small group of rocks belonging to this reef, and situated three miles westward of the light-house, is known as Stevenson's rocks.

SKEW, a sloping water-table—as on the set-off of a buttress, the cope of a gable, &c. This term is more generally used in Scotland than in England. The large stone (A) at bottom is called the skew-putt.



Skew.

SKEW-BRIDGE, a bridge placed obliquely so as to cross a road or river at an angle not a right angle. Such bridges, built of stone, are not easy of construction, owing to the peculiar twisted forms which the voussoirs assume, and were scarcely ever used till the necessities of railway curves compelled their introduction. They are evidently a great improvement on the old-fashioned mode of twisting a road, first to the right, and then to the left, in order to get the bridge at right angles to the place to be crossed. Since the introduction of iron girders as the supports of bridges, skew-bridges have become easy of construction, and are now quite generally used.

SKIBBEREE'N, a market-town of the county of Cork, Ireland, and situated in lat. 51° 34′ N., long. 9° 16′ W., distant from Cork 52 miles south-west. It is a place of little commerce, and almost entirely without manufactures. The pop. in 1881 was 3631, of whom 3209 were Roman Catholics.

SKID, in Military and Naval Language, is any timber which is used as a base to keep one object from resting on another. Thus, a row of cannon in store will be kept from the ground by skids. The term is also applied to the drag which is put on the wheels of carriages in going up hills, to prevent rolling backwards.

SKI'DDAW, a mountain in Cumberland, near the center of the county; height, 3054 feet. A few miles to the south lie Derwent Water and the town of Keswick.

SKIN. Considered in its general physiological and histological (or textural) relations, the skin is merely a part of the great mucous system to which the mucous membrane and secreting glands also belong, and which consists of two essential elements—a *basement tissue*, composed of simple cutaneous membrane, and an *epithelium* of nucleated particles resting on it—while beneath the basement membrane are vessels, nerves, and connective tissue. See EPITHELIUM and MUCOUS MEMBRANES. In the skin, the hard and thick epithelium is termed *cuticle* or *epidermis*, and the true skin below it is termed the *derma* or *cutis vera*, and is chiefly formed of modified and very dense connective (or areola or cellular) tissue.

The external surface of the skin formed by the cuticle is marked by furrows of different kinds. Some (termed furrows of motion) occur transversely in the neighborhood of joints, on the side of flexion; others correspond to the insertion of cutaneous muscles; while others, of quite another kind, are seen in aged and emaciated persons, and after the subsidence of any great distention of the integument; and besides these coarse lines, most parts of the skin are grooved with very minute furrows, which assume various courses in relation to one another. These minute furrows are most distinctly seen on the palmar aspect of the hand and fingers, and on the sole of the foot. The outer surface of the skin also presents innumerable pores for the discharge of the contents of the sudoriparous and sebaceous follicles, or the sweat and fat glands; and the modifications of epidermis known as hair and nails occur on the same surface.

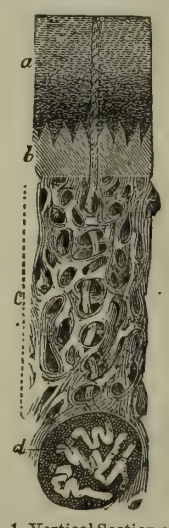


Fig. 1. Vertical Section of the Skin of the Sole:
a, Cuticle; *b*, Papillary structure; *c*, *Cutis vera*, or true skin; *d*, Sweat-gland lying in a cavity on the deep surface of the skin, and imbedded in globules of fat. Its duct is seen passing to the surface. Magnified about 30 diameters.

The deep layer of the skin consists of connective tissue, in which both the white and yellow fibrous elements are considerably modified as to the proportions in which they occur, and smooth muscles are present in no inconsiderable quantity in some parts of the skin. Where great extensiblity, with elasticity, is required, the yellow (elastic) element predominates; and where strength and resistance are specially required, as in the sole of the foot, the *cutis* is chiefly composed of a dense interweaving of the white (inelastic) element. The thickness and strength of this layer differ greatly in different parts, according to the amount of resistance required against pressure. The skin is thicker on the hinder surface of the body than in front, and on the outer than on the inner, sides of the limbs. 'It is unusually thin over the flexures of the joints. It is particularly delicate in the eyelids, and proportionably so in some other situations where great mobility is demanded. In regions which are most subject to external pressure, as the soles of the feet,

it is firmly united by very dense laminæ to the subcutaneous fascia; and the intervals between these are provided with pellets of fat, forming a cushion, as an additional means of protection to the delicate organs it encloses and covers. Amongst the lower animals, we may notice numberless examples of an analogous kind.'—Todd and Bowman's *Physiological Anatomy and Physiology of Man*, vol. i. p. 407. The blubber of the whale merely represents, in a very exaggerated form, the layer of fat which generally occurs in the subcutaneous areolar tissue of man and most animals, serving as a soft bed on which the skin may rest, and gives the appearance of plumpness and symmetry to the outline of the body. It is on the external surface of the cutis that the *tactile papillæ*, or true organs of touch, are developed.

Kölliker divides the true cutis into the 'reticular' and 'papillary' portions, the latter being the reddish-gray external superficial layer which contains the upper portion of the hair follicles and cutaneous glands, and whose most important element is these tactile papillæ. They are most abundant and largest in the palm of the hand* and the sole of the foot, while in the back and in the outer sides of the limbs, they are almost entirely absent. They occur as small, semi-transparent, flexible elevations (see *b*, in fig. 1), which are usually conical or club-shaped in form; but in certain parts, as the palm of the hand, present numerous points (in which case they are termed compound papillæ).

The thickness of the true skin varies, according to Kölliker, from $\frac{1}{4}$th of a line to a line and a half. In its chemical characters,

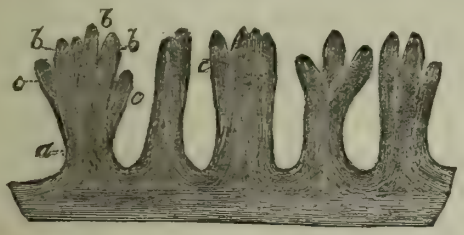

Fig. 2.—Compound Papillæ of the Surface of the Hand, with Two, Three, and Four Points:

rived mainly from the white fibrous tissue, and it is probably this element which is principally concerned in the changes which skin undergoes in the process of tanning. Arteries from the subcutaneous connective tissue freely enter into the structure of the skin, and are distributed to the fat-lobules, the sudoriparous and sebaceous glands (presently to be described), the hair follicles, the papillæ, &c. In these several parts, they terminate in a close network of capillaries. The two accompanying diagrams illustrate the mode in which these capillaries are distributed over the fat-cells and in the papillæ. Those parts of the skin which border upon the epidermis are for the most part very freely provided with nerves, while in the deeper parts the nervous filaments are comparatively scanty. How they terminate, is still a subject of dispute; but the view most generally adopted is that they end in loops.

The glands occurring in the skin next claim our consideration. They are the *sudoriparous* or *sweat glands*, the *sebaceous* or *fat glands*, and the *ceruminous glands*. The *sweat-glands* exist in almost every part of the human skin. They lie in small pits in the deepest parts of the true skin, and sometimes entirely below the skin. Their orifices can be seen in the middle of the cross grooves that intersect the ridges of the papillæ on the hands and

Fig. 4.—Arrangement of the Capillary Loops in the Skin.

feet, their arrangement being here necessarily regular, while in other parts they are irregularly scattered. Their size and number in different regions of the skin correspond with the amount of perspiration yielded by each part; thus they are nowhere so much developed as in the axilla, or armpit. In that part of this region, which in the adult is more or less covered with hair, they form a layer of a reddish color, of about an eighth of an inch thick. They are soft, and more or less flattened by their pressure on one

another, being imbedded in delicate connective tissue, and covered and permeated with a network of capillaries. On isolating one of these glands, and highly magnifying it, it is found to consist of a solitary tube, intricately ravelled, one end of which is closed, and hidden within the glandular mass, while the other emerges from the gland. The wall of the tube consists of an outer or *basement membrane*, with which the blood-vessels are in contact, and an *epithelium*, lining the interior, the former disappearing when the tube reaches the surface of the papillæ. The duct, on leaving the gland, follows a meandering and rather spiral direction through the reticular portion of the cutis to the interval between the papillæ, when it becomes straight; and it again assumes a spiral course in perforating the cuticle (see fig. 1). It is not easy to explain how or why so beautifully regular a spiral form should be given to the cuticular portion of the duct, which is rather wider than the rest, the average diameter of the duct being $\frac{1}{1700}$th of an inch.

The *sebaceous glands* are small whitish glands, which exist in almost every part of the skin, except the palms and soles, and are especially abundant in the scalp, face (the nose being particularly rich in them), and about the anus. They are usually connected with the hairs, as shown in fig. 7, and consist of a duct terminating in a blind pouch-like or pear-shaped extremity. The *basement membrane* of these glands is lined by an epithelium, in the particles of which are included granules of fatty or sebaceous matter, which, having become detached, constitutes the secretion. These glands are the seat of the parasite known as *Acarus folliculorum*.

The *ceruminous glands* are brown simple glands, in external appearance like the sudoriparous glands, occurring in the cartilaginous portion of the external meatus of the ear. They yield an adhesive bitter secretion, which protects the membrane of the tympanum from the access of dust, insects, &c.

We shall conclude by taking a brief survey of the functions of the skin, omitting, however, its most important function, TOUCH (q. v.). Regarded as a protective covering, the skin possesses the combined advantages of toughness, resistance, flexibility, and

* In one square line of the palm of the hand, E. H. Weber reckons that there are 21 compound, and from 150 to 200 smaller papillæ, arranged in tolerably regular rows.

elasticity; the connective framework being the part which mainly confers these properties, although the epidermis co-operates with it. The subcutaneous layer of fat, and the modifications of epidermis in various forms, as hairs, wool, feathers, scales, &c.,

(With two exceptions, the diagrams in this article are borrowed from Todd and Bowman.)

serve for the preservation of warmth, and occasionally (when they occur as claws, talons, &c.) as means of offence or defence.

The skin is the seat of a twofold excretion—viz., of that formed by the sudoriparous glands, and that formed by the sebaceous glands. The fluid secreted by the sudoriparous glands is usually formed so gradually that the watery portions of it escape by evaporation as soon as it reaches the surface; but in certain conditions, as during strong exercise, or when the external heat is excessive, or in certain diseases, or when the evaporation is prevented by the application of a texture impermeable to air, as, for example, oiled silk, or the material known as mackintosh, or india-rubber cloth, the secretion, instead of evaporating, collects on the skin in the form of drops of fluid. When it is stated that the sweat contains urea, lactates, extractive matters, &c., and that the amount of watery vapor exhaled from the skin is, on an average, 2½ lbs. daily (according to Valentine's observation), the importance of the sudoriparous glands as organs of excretion will be at once manifest. Moreover, there is reason to believe, from the experiments of Scharling, Gerlach, and others, that the importance of the skin as a *respiratory* organ is far from inconsiderable, very appreciable quantities of carbonic acid being exhaled hourly by the external surface of the body. In the amphibia, in which the skin is thin and moist, the cutaneous respiration is extremely active; and that the respiratory function of the skin in the higher animals is also considerable, is proved not only by measuring the excreted carbonic acid, but by the fact, that if the skin is covered with an impermeable varnish, or if the body be enclosed, all but the head, in a caoutchouc dress, animals soon die, as if asphyxiated, their heart and lungs being gorged with blood, and their temperature before death gradually falling many degrees. The secretion of the sebaceous glands is a semi-fluid oily mass, which often solidifies into a white viscid tallow-like matter on the surface or in the glandular ducts, from which it can be removed by pressure, in a form resembling that of a small whitish worm or maggot. Under the microscope, cells containing fat, free fat mixed with epidermic scales, and sometimes chrystals of cholesterin, are observed. Its chemical constituents, in addition to water, are a peculiar nitrogenous matter resembling casein, fat (consisting of palmitin and olein, soaps composed of palmitic and oleic acids), cholesterin, earthy phosphates, and chlorides and phosphates of the alkalies. Its purpose seems to be that of keeping the skin moist and supple, and by its oily nature, of hindering too rapid evaporation. Moreover, considered as an excretion, it must take a share in the purification of the blood.

The skin is, moreover, an organ of absorption: mercurial preparations, when rubbed into the skin, have the same action as when given internally, Potassio-tartrate of antimony, when rubbed into the skin in the form of ointment or solution, may excite vomiting, or an eruption extending over the whole body; and many other illustrations might be given. The effect of rubbing is probably to force the particles of the matter into the orifices of the glands, where they are more easily absorbed than they would be through the epidermis. It has been proved by the experiments of Madden, Berthold, and others, that the skin has the power of absorbing water, although to a less extent than occurs in thin-skinned animals, such as frogs and lizards. This fact has a practical application. In severe cases of dysphagia—difficult swallowing—when not even fluids can be taken into the stomach, immersion in a bath of warm water, or of milk and water, may assuage the thirst. Sailors, also, when destitute of fresh water, find their urgent thirst allayed by soaking their clothes in salt water.

The *diseases* of the skin and their classification into genera and species, have occupied much attention; but none of the proposed classifications is very satisfactory. The more important affections are noticed in special articles. See ECZEMA, and ECTHYMA; also Quain's *Anatomy*.

SKINK. See SCINK.

SKIPS, large square baskets, lined with leather or skin, used in spinning-mills for carying the bobbins of yarn; sometimes they are made entirely of thick hides. Wood or basket work would be apt to catch and break the delicate threads.

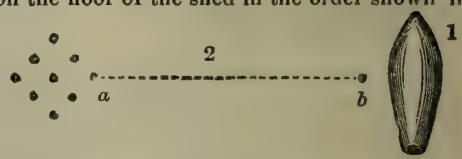
SKI'PTON, a market-town of England, County of York, is finely situated in a broad and fertile valley, near the river Aire, about 38 miles west of York, and 16 north-north-west of Bradford. S. carries on manufactures of cotton and woollen goods, and is a station on the Leeds and East Lancashire Railway and on the Midland line. Pop. (1881) 9091.

SKI'RMISHERS are soldiers operating in loose array, two together i. e., front and rear, with a lateral distance of about six paces between the files. When the army advances, the ground in front, and for some distance on each flank, is usually covered by skirmishers, to prevent surprise. If cavalry come suddenly on them, they rush together, and form small squares, called rallying squares. Skirmishers fire independently at their own discretion; but the rule is, that one of the two men composing a file should always have his rifle loaded. Orders are communicated by the sound of bugle.

SKI'RRET (*Sium Sisarum*), a perennial plant of the natural order *Umbelliferæ*, a native of China and Japan, but which has long been cultivated in gardens in Europe for the sake of its roots, which are tuberous and clustered, sometimes 6 inches long, and of the thickness of the finger. They are sweet, succulent and nutritious, with a somewhat aromatic flavor, and when boiled, are a very agreeable article of food. A kind of spirituous liquor is sometimes made from them. Good sugar can also be extracted. S. was at one time more cultivated in Britain than it is at present, although there seems to be no good reason for its having fallen into disrepute. It is propagated either by seed or by very small offsets from the roots. It has a stem of 2—3 feet high; the lower leaves pinnate, with oblong serrated leaflets, and a heart-shaped terminal leaf, the upper ones ternate with lanceolate leaflets.

SKI'RTING, the board round the bottom of the walls of rooms. When large, it is called a base-plinth.

SKI''TTLES, a game very popular in England amongst the frequenters of public houses. It is usually played in a covered shed, called a skittle alley, about 60 feet in length. The skittles are made of hard wood of the shape shown in fig. 1, and they are placed upon the floor of the shed in the order shown in fig. 2, *a*.



Skittles.

The player, standing at *b*, throws a wooden ball, and tries to knock down the whole of the skittles in a given number of throws. The rules of the game vary in different places. It is sometimes called 'Ninepins,' from the number of skittles used.

SKOPI'N, a town of Russia, government of Riazan, and 160 miles south-east of Moscow, is situated on the Verda, a tributary of the Oka, which is itself a tributary of the Volga. It has manufactures of Russian leather, and a trade in corn and cattle. Pop. (1880) 9500.

SKU'A, or SKUA GULL (*Lestris*), a genus of birds of the family *Laridæ*, also known by the name JAGER (Ger. hunter), and differing from the gulls in having the upper mandible more hooked at the tip, and the nostrils larger and further forward in the bill, the base of which is covered with a cere. The skuas are bold and powerful birds, and generally obtain their food by pursuing gulls or terns, and causing them to disgorge the fish which

they have captured, which they dart upon and seize in the air. They also eat eggs and small birds. The COMMON S. (*L. cataractes*) is fully two feet in length, of a brown color, with lighter streaks

Common Skua (*Lestris cataractes*), in pursuit of a Gull.

on the head and neck. It inhabits the northern seas, and breeds in some of the Shetland isles.

SKULL. The skull is divided into two parts, the cranium and the face. In human anatomy, it is customary to describe the former as consisting of eight, and the latter of fourteen bones; the eight cranial bones, which constitute the brain-case, being the *occipital, two parietal, frontal, two temporal, sphenoid,* and *ethmoid;* while the fourteen facial bones are the *two nasal, two superior maxillary, two lachrymal, two malar, two palate, two inferior turbinated, vomer,* and *inferior maxillary.* The bones of the ear, the teeth, and the Wormian bones are not included in this enumeration. The morphologist, however, who wishes to trace out the fundamental similarity of type in the structure of the various modifications of the vertebrate skull will not be content with this arrangement, in which, as, for example, in the occipital, temporal, and sphenoid bones, the human anatomist considers as a single bone an osseous mass consisting primarily in man, and persistently in some of the lower vertebrates, of several distinct pieces

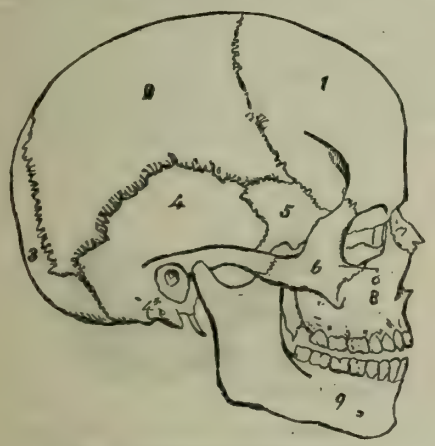


Fig. 1.—Side-view of Human Skull:

1, Frontal bone; 2, Parietal bone; 3, Occipital bone; 4, Temporal bone (squamous portion); 4*, Do (mastoid portion); 5, Sphenoid bone; 6, Malar bone; 7, Nasal bone; 8, Superior maxillary or jaw bone; 9, Inferior maxillary or jaw bone.

or elements. Postponing to the close of this article any remarks on the structure of the vertebrate skull generally, we shall proceed to notice the ordinary anatomical relations of the human skull. The development of the skull is a subject of great interest not only in itself, but as throwing light on many points which the study of the adult skull would fail to explain. At a very early period of fœtal existence, the cerebrum is enclosed in a membranous capsule external to the dura mater, and in close contact with it. This is the first rudiment of the skull, the cerebral portion of which is consequently formed before there is any indication of a facial part. Soon, however, four or five processes jut from it on either side of the mesial line, which grow downwards, incline towards each other, and unite to form a series of inverted arches, from which the face is ultimately developed. Imperfect development or ossification of these rudimentary parts of the face gives rise to the peculiarities known as 'hare-lip' and 'cleft-palate,' or in very extreme cases to the form of monstrosity termed 'Cyclopean,' in which, from absence of the frontal processes, the two orbits form a single cavity, and the eyes are more or less blended in the mesial line.

The following is a brief summary of the succession of events that occur in the ordinary or normal development of the skull. Cartilage is formed at the base of the membranous capsule, which has been already described as thrown around the brain, and capable of enlarging with it. This is speedily followed by the deposition of ossific matter at various points of the capsule, which soon becomes converted into flakes of bone, which afford protection for the brain, while the intervening portions, which remain membranous, permit the skull to expand as its contents enlarge. The formation of these bony flakes on the convexity of the cranium is soon followed by the appearance of osseous nuclei in the cartilage at the base, corresponding to the future occipital and sphenoid bones. Lastly, the various bones, some originating in membrane, and some in cartilage (as described in the article OSSIFICATION), approach one another by gradual enlargement, and become united in various ways, so as to form a continuous, and ultimately an unyielding bony case, which, in the words of of Dr. Humphry, 'is admirably adapted for the defence of the brain, for the accommodation of the organs of special sense, and for the attachment of the ligaments and muscles by which the skull is supported and moved on the spine.'—*The Human Skeleton,* p. 185. At the period of birth, most of the principal bones have grown into apposition with their neighbors, forming the *Sutures* (q. v.), but one large vacuity remains at the meeting-point of the parietal and frontal bones, which is termed the anterior fonta-

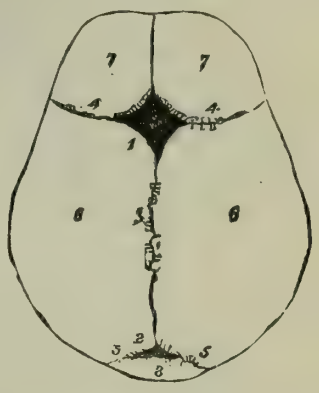

Fig. 2.

1, Anterior fontanelle; 2, Posterior fontanelle; 3, Sagittal suture; 4, 4, Coronal suture; 5, Lambdoidal suture; 6, 6, Parietal bones; 7, 7, Two halves of the frontal bone, still ununited; 8, Occipital bone.

nelle,* which does not close till the second year after birth, and sometimes remains open much longer.

The deficiency of the osseous brain-case at this position not only facilitates the act of delivery, but also acts, according to Humphry, 'to some extent like a safety-valve during the first months of infantile life, at which time the brain bears an unusually large proportion to the rest of the body, and is liable to sudden variations of size from temporary congestion, sudden wasting of its

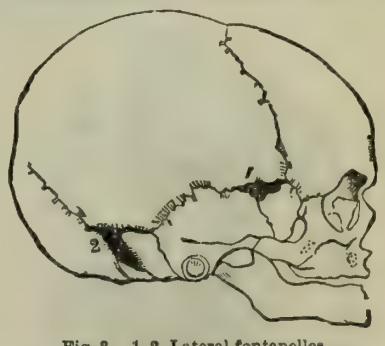

Fig. 3.—1, 2, Lateral fontanelles.

substance, and other causes. The sutures remain distinct long after the closure of the fontanelles, and probably serve a purpose both in permitting an increase of the size of the cranium by the growth of the bones at their edges (although the enlargement of the cranial cavity does not entirely depend upon this growth at the edges), and in diminishing and disbursing vibrations from blows, and thus contributing to the security of the brain.

The number of centers of ossification in the skull is tolerably constant; each bone having a certain number. (Thus, the occipital has 7 centers, the temporal 5, the sphenoid 12, &c.; the total number being about 59.) In addition to these, centers frequently occur in the course of the sutures, giving rise to independent pieces, which are called the *ossa triquetra,* or the *Wormian bones.* They are regarded by Humphry as stop-gaps, developed in the membranous

* So called from the pulsations of the brain, which may be here seen resembling the rising of water at a spring or fountain. There are two fontanelles in the mesial line, as shown in fig. 2, and two lateral fontanelles on either side, as shown in fig. 3.

covering of the brain, when the extension of the regular osseous nuclei is likely, for some reason, to be insufficient to cover in the cranial cavity; and this view is supported by the observation that, in cases of rickets and hydrocephalus, the Wormian bones are especially abundant.

After the sutures have been formed, and the skull has acquired a certain thickness, a process of resorption commences in the interior of the bones, and reduces the originally dense structure to a more or less cellular or cancellated state. The interior thus altered is called the *Diplöe*, and by this change the weight of the skull is much diminished, while its strength is scarcely affected.

The diplöe usually begins to be apparent about the tenth year, and is most developed in those skulls which are thickest. Dr. Humphry has observed it to be especially thick in idiots, and where the brain is small. 'Hence,' he observes, 'the propriety of the term *thick-headed*, as a synonym for *stupid*, derives some confirmation from anatomy.' A continuation of the same process of resorption, which causes the diplöe, gives rise to the formation of the cavities known as the frontal and sphenoid sinuses. The formation of the diplöe divides the walls of the cranium into three layers, viz., an outer tough layer; an inner dense, brittle, and somewhat glass-like layer, known as the vitreous table or layer; and the intervening cancellous diplöe. The vitreous table being more brittle than the outer layer, is apt to be fissured to a greater extent in fracture of the skull; and is even sometimes broken while the outer layer, which received the blow, has remained entire; although the diplöe must have great power in lessening the concussions transmitted from the outer to the inner layer of the skull. The growth of the skull after the seventh year proceeds slowly, but a slight increase goes on to about the age of twenty. The skull-bones are freely supplied with blood from arteries which pass from the dura mater internally and the pericranium externally, through the numerous foramina observed on both surfaces; the blood being returned by veins which take various directions.

The fact that concussion of the brain scarcely ever proves fatal, unless there is also fracture of the skull, affords the most distinct evidence that the skull is constructed in such a manner that so long as it maintains its integrity, it is able to protect its contents from serious lesion. This marvelous protective power is due to its rounded shape, whereby its strength is increased, and in consequence of which blows tend to glide off it, without doing material damage. Moreover, the curved lines or ridges which may be traced round the skull tend to strengthen it. The weakest part of the skull is at the base. Hence, notwithstanding its removal from exposure to direct injury and the protection afforded by the soft parts, fracture takes place more frequently at the base than at any other part of the skull, fracture often taking place here even when the skull was not broken at the part struck. There are two points in the architecture of the bones of the face which deserve especial notice, viz. (1), the great strength of the nasal arch, and (2) the immobility of the upper jaw, which is fixed by three buttresses, the nasal, the zygomatic, and the pterygoid.

The base of the skull, whether seen from within or from below,

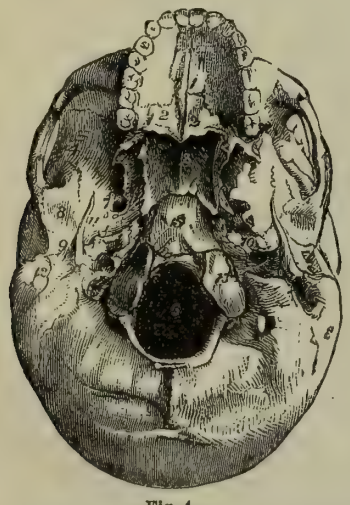

Fig. 4.

1, 1. Hard palate, formed by the palate processes of the superior maxillary bone; 2, 2, Palate bones; 3, Vomer, dividing the openings of the posterior nostrils; 4, Zygomatic fossa; 5, Basilar process of the occipital bone; 6, Foramen magnum, through which the spinal cord passes; 7, Foramen ovale; 8, Glenoid fossa, in which the head of the lower jaw-bone lies: 9, External auditory foramen; 10, Carotid foramen of the left side; 11, Styloid process; 12, Mastoid process; 13, One of the condyles of the occipital bone.

presents many objects of physiological interest, in relation to the nervous system. As seen from within, the base presents on each side three fossæ, corresponding to the anterior and middle lobes of the cerebrum and to the cerebellum. These fossæ are marked, as is the whole skull-cap, by the cerebral convolutions, and they contain numerous 'foramina' and 'fissures' which give passage to various sets of nerves and blood-vessels. The external or outer surface of the base of the skull, if we consider it from before backwards, is formed by the palate processes of the superior maxillary and palate bones; the vomer; the pterygoid and spinous processes of the sphenoid and part of its body; the under surface of the temporal bones, and by the occipital bone. The most important of the parts which it presents are named in the description of fig. 4.

The anterior region of the skull, which forms the face, is of an irregularly oval form, and the bones are so arranged as to enclose the cavities for the eyes, the nose, and the mouth, and to give strength to the apparatus for masticating the food. The size of the face and the capacity of the cranial cavity stand in an inverse ratio to one another, as may be readily seen by comparing vertical sections (through the mesial line) of human and other mammalian skulls; and if, in place of mammalian skulls, we take skulls of lower vertebrates (the crocodile, for example), this ratio is far more striking. In man, the face is at its *minimum* as compared with the cranial cavity; chiefly in consequence of the facial bones being arranged in a nearly vertical manner beneath the cranium, instead of projecting in front of it. The human face is also remarkable for its relatively great breadth, which allows the orbits for the reception of the eyes to be placed in front instead of on the sides of the head, and renders their inner walls nearly parallel. 'This parallelism,' says Dr. Humphry, 'in man is associated with the parallelism of the optic axes, and contributes to that clear, accurate, and steady vision which results from the ready convergence of the eyes upon every object.' Each orbit is of a pyramidal form, with the apex behind, and is composed of seven bones—viz., the frontal, ethmoid, lachrymal, sphenoid, superior maxillary, malar, and palate, which last contributes very slightly to the human orbit, but is an important constituent in the orbit of many animals. The nasal cavities have been sufficiently described in the article NOSE.

The different varieties of mankind present certain well-marked and characteristic peculiarities in the form of the skull. There are *three typical forms* of the skull which seem to be well established from the examination and comparison of a large number of crania, viz., the *prognathous*, the *pyramidal*, and the *oval* or *elliptical* cranium. When the upper jaw slopes forward, the insertion of the teeth, instead of being perpendicular, is oblique. A skull with

Fig. 5.—Prognathous Skull of a Native Australian.

this peculiarity is *prognathous* or *prognathic* (Gr. *pro*, forwards, and *gnathos*, a jaw); the opposite condition being termed *orthognathous* or *orthognathic* (Gr. *orthos*, upright). The Negro of the Guinea Coast and the Negrito of Australia present the prognathous character in its most marked form. The pyramidal form is characterized by the breadth and flatness of the face, which with the narrowness of the forehead, gives this shape to the head. The Mongolian and Esquimaux skulls belong to this type. The oval or elliptical type is that which is presented by the natives of Western or Southern Europe, and which is not distinguished by any particular feature so much as by the absence of the longitudinal projection of the first type, or the lateral projection of the second, and by a general symmetry of the whole configuration. The length of the skull, which to a great degree corresponds to the degree of development of the posterior cerebral lobes, has been taken by the late Professor Retzius as a basis of classification. He arranges all the varieties of mankind into two great classes—the *Dolicocephalæ*, or *long-heads*, whose cerebral lobes completely cover the cerebellum; and the *Brachycephalæ*, or *shortheads*, in whom the cerebral lobes do not extend so far. Each of these classes contains *orthognathous* and *prognathous* varieties. See ETHNOLOGY.

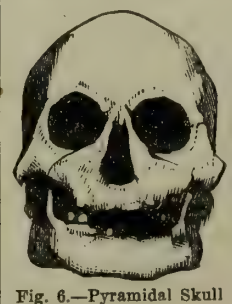

Fig. 6.—Pyramidal Skull of Mongolian Race.

The *Morphology of the Skull* is the highest and most difficult problem of comparative anatomy, and has cost the most extraordinary labor for its solution. Goethe and Oken independently suggested that the skull was to be regarded as the modification of a series of four vertebræ, and this 'vertebral theory' was worked out in the most elaborate detail by Owen and other anatomists (see SKELETON). Huxley, however, in a celebrated Croonian Lecture (1858), revised and extended the hitherto neglected embryological observations of Rathke, proposed an unanswerable destructive criticism of the archetypal theory, and may be said to have thus definitely placed the newer view in the way of general acceptance. An enormous amount of detailed research, for which we are indebted chiefly to Parker in England, and Gegenbaur in Germany, and which is still in progress, has established the newer theory on sure grounds of actual observation.

Taking first the simple unsegmented cartilaginous cranium of a skate or dog-fish, with its appended jaws and branchial arches, we find that in development, though the notochord extends into the region of the head, the vertebræ stop altogether short of it; but that on each side of the cranium there arise a pair of cartilaginous bars—the *trabeculæ* or 'rafters' of the future skull—three pairs of cartilaginous capsules, nasal, ocular, and auditory, form round the developing sense organs; the nasal capsules immediately unite with the ends of the trabeculæ, which are meanwhile uniting below, and growing up at the sides to form the brain-case. The auditory capsules become united with the trabeculæ by the appearance of two new masses of cartilage—the parachordals—the eyes of course remaining free. At first there are no jaws, but a series of seven or more similar vertical cartilaginous bars or arches, considerably resembling the trabeculæ, between which slits open into the pharyngeal cavity. The first pair of these arches develops an ascending process, which passes above the developing mouth, and becomes the 'palato-pterygoid' arch or upper jaw, the original portion remaining as the mandible. The second pair of arches—the 'hyoid'—becomes more or less modified usually to aid in supporting the jaws and floor of the mouth, while the remaining pairs become little modified, and serve throughout life to support the gills.

The more complex bony skulls of higher vertebrates are now in principle readily understood. The chondro-cranium and subjacent arches in all cases develop in the same way, although reduction and even atrophy of the gill arches subsequently takes place. The bones, although similar in the adult, originate in two utterly distinct ways, either by actual ossifications in the substance of the chondro-cranium and jaws, or by the ossification of overlying dermis, and are hence known as cartilage bones and membrane bones respectively—the latter corresponding to the dermal bones and teeth of ganoid and elasmobranch fishes. In mammals, a further extraordinary specialization takes place: the ends of the mandibular and hyoid arches lose their suspensory function, are taken up during development into the interior of the ear capsule, and are metamorphosed into the auditory ossicles.

See article on SKELETON; Huxley's *Croonian Lecture* 1858; Huxley's *Anat. of Verteb. Animals*, 1871; Parker's *Morphology of the Skull*, 1877; and for summary, Balfour's *Embryology*, vol. ii.

Fracture of the skull may take place either in the vault or at the base of the skull. We shall first consider *fractures of the vault*. Here the fracture is usually direct, the bone giving way at the point at which it was struck, and the result being either a simple fissure, or a breaking of the bone into several fragments (a comminuted fracture). Although fractures may be limited to the outer or to the inner surface of the skull, they most commonly extend through the whole thickness, and the broken bone is generally driven inwards; and the most ordinary form of fracture with depression is that in which several fragments of a somewhat triangular form have their points driven down and wedged into each other, while their bases remain on a level with the surrounding bone. There are no signs by which we can in all cases recognize the existence of fracture of the vault.

Fissures constantly exist without ever having been suspected during life. When, however, the fracture is accompanied by a wound leading down to the bone, it may, in general, be easily detected. With regard to treatment, it is now an established rule, that 'simple fractures of the skull with depression, and without symptoms, are to be left alone. The depression may be so marked as to be easily detected; and yet so long as there are no symptoms, all operative interference, of whatsoever form, is carefully to be avoided.'—Prescott Hewett, *op. cit.* If, however, there be a wound leading down to the bone in a depressed fracture without symptoms, immediate operative interference is called for. When a depressed fracture is accompanied by primary brain-symptoms, an operation for the purpose of raising or removing the depressed fragments is usually necessary. If, however, the fracture is a simple one, and the symptoms are not urgent, milder remedial agents, as bleeding, purging, and low diet, may be first tried.

Fractures of the base may be direct or indirect, but in most cases are indirect, that is to say, the bones give way at a point remote from the seat of the blow, as has been already shown. At certain parts, however, the bones of the base are so thin, that if direct pressure be brought to bear upon them, they readily give way. Thus scissors, slate-pencils, tobacco-pipes, &c., have often been thrust into the skull through the orbits of the nostrils, and these wounds are very serious, from the readiness with which the brain may be thus injured. The only symptoms that can be depended upon as indicating a fracture of the base of the skull, are connected either with an escape of the substance of the brain, or blood, or watery fluid, or with an injury done to the nerves as they emerge at the base. Out of 32 cases of fractured base observed by Hewett, bleeding from the mouth or nose occurred in 14 and bleeding from the ear in 15 cases.

SKUNK (*Mephitis*), a genus of quadrupeds of the weasel family (*Mustelidæ*), but departing very considerably from the typical characters of that family, and approaching to the badgers and gluttons in general appearance, in habits, in the lengthened claws of the fore-feet, in the plantigrade hind-feet, and in some of the teeth. There are six incisors and two canine teeth in each jaw, eight molars in the upper, and ten in the lower; the teeth

Common Skunk (*Mephitis varians*).

generally resemble those of the polecat. Skunks depend very much for defence against enemies on an excessively fetid fluid, which is secreted by glands near the anus; and when assailed, they turn the rump towards the assailant, elevate the tail, and discharge this fluid with considerable force. The odor proceeding from it, even when a dead S. had been flung into an enclosure has been known to cause nausea to the inmates of an apartment with closed windows at the distance of 100 yards. So confident does the S. seem of the efficacy of its peculiar mode of defence, that it permits itself to be approached till it is just on the point of being seized, which, however, is only attempted by the inexperienced, when the battery is discharged. It is almost impossible to remove the odor from clothes. Dogs flee at once, and rub their noses on the ground till they bleed. Dogs that are aware of the S.'s powers, however, kill it by leaping upon it suddenly, and in such a way that they are not exposed to danger. There is much uncertainty concerning the species of S., as the colors vary considerably even in the same species; but there is no doubt of the existence of a number of species. They are found only in America, where they are very widely distributed from Hudson's Bay, to the Strait of Magellan. The COMMON S. (*M. Americana* or *varians*) is about the size of a cat, generally black or blackish brown, with white streaks along the back. It inhabits burrows which it makes in the earth, feeds on mice, frogs, &c., and also on insects and fruits; and sometimes enters houses to plunder storerooms, where, if it is suddenly alarmed, everything is tainted with an intolerable odor. White streaks on the back, one or more, are very characteristic of this genus.

SKYE, the largest of the Scottish islands after Lewis, and the most northerly of the group known as the Inner Hebrides, forms part of the county of Inverness, from the mainland of which it is separated by a channel scarcely half a mile in breadth at its narrowest point, Kyle Rhea. Its extreme length, from south-east to north-west, is 47 miles; breadth, from 7 to 25 miles; but on account of the extraordinary number of inlets at all parts of the island, no point is above 4 miles from the sea. Area, 547 sq. m.; pop. (1871) 17,330; (1881) 16,099. S. is for the most part mountainous and moory, but it contains some pleasant tracts of arable and pasture land, and one considerable plain, formerly the bed of a lake, in the parish of Kilmuir, where some ruins of a religious house called after St. Columba were found. The principal mountains are the Coolin Hills (not Cuchullin), which stretch irregularly chiefly from south-west to north-east, terminating in the sharp peak of Scoor-nan-Gillean (3167 feet) above Sligachan. Another peak, Scoor Dearg, has been found to be the highest of the range (3233 feet), but Scoor-nan-Gillean will still be regarded as the chief of the Coolin Hills. The jagged outline of these remarkable hills arrests the eye at a great distance, and forms the dominant feature in the view at almost every point round the island, and far out at sea. The rock of which they are composed, hypersthene, is not found in any other part of Britain. The most

famous scene in this region is Loch Coiruisg, a small lake near the head of the bay of Scavaig, all but encircled by frowning ridges of rock, shooting up at several points to heights above 3000 feet. It has been powerfully depicted by Sir W. Scott in *The Lord of the Isles*. Glen Sligachan, extending from the head of the loch of that name about 9 miles to Camusunary, is by many considered the grandest glen in the Highlands. The scenery of Cuiraing, near the north of the island, has been truly styled 'unique.' The same may be said of Storr. The coast-scenery is for the most part highly picturesque. Between Rhunam-Brarin and Loch Staffin, on the east side, it presents columnar trap formations on a grand scale.

On the west side, at Galtrigill and Vaterstein, the cliffs reach a height of 1000 feet. Over these cliffs descend many remarkable waterfalls, and their bases are frequently worn into deep caves, some of which are of historical interest. One, near Portree, afforded a refuge to Prince Charles; another, on the west coast, was the temporary prison of Lady Grange. The largest arms of the sea are Loch Bracadale, Loch Dunvegan, and Loch Snizort; and the chief harbors are those of Portree, Uig, Grishernish, Lochbay, Dunvegan, Pooltiel, and Harport.

The coasts abound in fish, the most important being herring, salmon, cod, and ling. Good oysters are found in several places. The herring-fishery is prosecuted in the season in all the bays; the cod and ling-fishery is chiefly confined to Loch Dunvegan and Loch Snizort; and the salmon-fishery to Portree and the east coast. Lobster-fishing is also carried on to a considerable extent. There are no rivers of any magnitude; but salmon and sea-trout are got in some of the principal streams, at Skeabost, Portree, Ose, Hammer, &c., and trout in most of the fresh-water lochs. Deer are not numerous, nor are grouse. West Highland cattle are reared to a considerable extent, but sheep-farming on a large scale predominates. The climate is exceedingly rainy, but mild and healthy. Agriculture in S. being comparatively unprofitable, owing to the moisture of the climate, is falling into entire neglect on some of the chief sheep-farms. The soil, however, is in many places excellent, and capable, in dry seasons, of yielding good cereal crops, while for turnips it is peculiarly suited.

The inhabitants are for the most part poor and ill-housed, but well-behaved and intelligent. At one time they contributed largely to the British army; not less than 10,000 private soldiers, it has been calculated, during the long war with France. The number of soldiers now sent from Skye is very small. In the districts where the men practise fishing, nearly the whole of the adult males go to the east coast fisheries in summer, while from all parts of the island young men and women go to the south in search of field-labor. Potatoes and fish are the general diet, meat being a rare luxury. The population is chiefly Celtic, with, however, a considerable mixture of the Norse element. Gaelic is still universally spoken, but is gradually giving place to English. The chief proprietors are still, as of old, Lord Macdonald, whose seat, Armadale Castle in Sleat, is one of the most beautiful in all its surroundings to be seen on the Scottish coasts, and Macleod of Macleod, whose ancient castle of Dunvegan, picturesquely seated on a rock, has been pleasantly commemorated by Dr. Johnson and Sir Walter Scott. The principal port of S. is Portree, a picturesquely situated village of (1881) 758 inhabitants, to which steamers regularly ply from Glasgow, and also from Strome Ferry, in connection with the Skye Railway thence to Inverness. Other villages, also calling-points of the steamers, are Kyleakin (Hakon's Strait), Broadford, and Dunvegan. The celebrated whiskey generally known as 'Tallisker,' is made at the distillery of Carabost, at the head of Loch Bracadale. The inhabitants are nearly all Presbyterians, and chiefly adherents of the Free Church.

Of books about S. the most interesting are, Boswell's *Tour in the Hebrides*, and Alexander Smith's *Summer in Skye*.

SKY'ROS, or SCYRO, an island of the Grecian Archipelago, the largest of the northern Sporades, 25 miles north-east of Eubœa. Length 19 miles; area 60 sq. miles. S. is very mountainous and uncultivated in the south; but the northern part, though also hilly, has several fertile plains, which produce as fine wheat as any grown in the archipelago. The only town in the island is Skyro, or St. George, which is built on a high peak on the eastern coast, the broad summit of which is occupied by the ruins of a castle, and was the site of 'the lofty Scyros' of Homer. There are several relics of antiquity in the island. Pop. 3250.

SLAGS, called otherwise Scoriæ or Cinders, are fused compounds of silica in combination with lime, alumina, or other bases; and result as secondary products from the reduction of metallic ores. More or less of the metal always remains in a slag; in the early days of iron-smelting, the proportion of metal thus wasted was so great, that some old slags have been profitably smelted in recent times. Slags being silicates, are of the nature of glass, and externally have a glassy, crystallized, or stone-like character. Beautifully crystallized specimens are occasionally to be met with at smelting-works. They vary very much in color, and are sometimes so prettily veined and marbled, that attempts have been made to apply them to ornamental purposes. Millions of tons of slag are annually produced at the iron-smelting works of Great Britain, but almost the only use to which it has yet been successfully applied is in the making of square blocks or bricks for building purposes. The slag is run into moulds, either as it issues from the blast-furnace, or after being remelted; and it is found to be a very durable material. Broken slag is also used as a covering for roads, but its brittleness and sharpness are objectionable qualities for this purpose. Several patents, beginning so far back as 1728, have been taken out for casting slag into articles of a more ornamental kind, but hitherto they have not been commercially successful.

In an archæological point of view, slags are interesting as pointing out the sites of ancient smelting-works, and as affording a clue to the primitive methods of obtaining the metals from their ores.

SLANDER is an injury to a person's character and reputation caused by spoken words. It is difficult to define what kind of injuries of this nature are actionable, but in general whatever imputes disgraceful, fraudulent, or dishonest conduct, or even tends to make a man contemptible, in his private relations, and shunned by his friends and neighbors, is a slander. Thus, whatever imputes a crime or indictable offence, or a contagious disease, is a slander. There are some epithets, however, which are not actionable unless some special damage is directly caused thereby, as calling a man a scoundrel, swindler, rogue, gambler, liar, &c. To call a woman a whore is also not actionable, unless she can show that she has lost offers of marriage, &c. thereby. Words imputing gross ignorance or misconduct affecting one's trade or profession, are, however, actionable, as calling a man a bankrupt grocer, a quack doctor, &c. See also LIBEL. The remedy for slander is an action at law for damages. Though certain words when spoken will not amount to slander, yet, if printed or written, they will sometimes become so, as calling one a rogue, swindler, rascal, &c.

SLANG, once assumed to have been borrowed from the gipsy tongue, but derived by Skeat from a Scandinavian source (see his *Etymological Dictionary*). In its usual signification, it denotes a burlesque style of conversational language, originally found only among the vulgar, but now more or less in use in this country among persons in a variety of walks in life. It is somewhat allied to, though not indentical with *cant* (in French *argot*), the language used for purposes of concealment by thieves and vagrants of all descriptions.

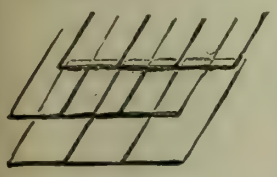
Slang is not exclusively of modern date. It was known in the classic ages of Greece and Rome, and abounds in the writings of Aristophanes, Plautus, Terence, and Martial. Every modern European language has its slang. In our country, the 'Rump,' the 'Barebones Parliament,' the terms 'Roundheads,' 'Puritans,' 'Quakers,' all belonged to the slang of the 17th century. *Hudibras* and the dramatic works of last century abound in slang. Old English slang was coarser than that now in use, but the greater portion of its phraseology had a somewhat restricted circulation, not permeating every species of conversation to the extent that modern slang does. Towards the close of last century, the slang vocabulary received large additions from pugilism, racing, and 'fast life;' and its fashionable vulgarisms came into great favor during the minority of the Prince Regent. In the present century, the growth of refinement in manners and ideas has not banished slang, but given it a more familiar and utilitarian character, while it has been introduced in some measure into circles where it was formerly unknown.

Slang consists in part of new words, and in part of words of the legitimate language invested with new meanings, such as are assigned to the verbs to *cut* to *do*. Many slang expressions are derived from thieves' cant, and some from the gypsy tongue. Their derivations are often indirect, arising out of fanciful allusions and metaphors, which soon pass out of the public mind, the word remaining, while its origin is forgotten. The origin of much of the current slang may be traced to the universities of Oxford and Cambridge, and the great public schools of England. There is not an institution connected with the university which has not its slang equivalent (e. g., 'plucked,' 'little go').

There is a slang attached to various professions, occupations, and classes of society. The slang of English fashionable life and fashionable novels comprises a number of French words and phrases, whose application is often very different from what is current in France. The *beau monde*, a *chaperon*, a marriage being on the *tapis*, are expressions which, in their English sense, are utterly unknown in Paris. To the slang of military life, Hindustani has contributed its quota of words, imported by officers who have resided long in India. We have also parliamentary slang, religious slang, literary slang, civic slang, and shopkeepers' slang.—Many curious details regarding slang in all its departments are to be found in Hotten's *Slang Dictionary* (Lond. 1865).

SLATE, or CLAY-SLATE (Fr. *esclat*, a shiver or splinter), is a highly metamorphosed argillaceous rock, fine-grained and fissile, and of a dull blue, gray, green, or black color. It splits into thin laminæ or plates, that are altogether independent of the layers of deposit; though sometimes coinciding with them, they more frequently cross them at different angles. See CLEAVAGE. Some rocks that split into the thin plates of the original stratification, are popularly but erroneously named slate, as the thin bedded sandstones properly called flagstones or tilestones, the fissile shales of Cambrian and Silurian age, and the metamorphic gneiss, and mica schist, whose planes of division correspond to their stratification. True slate is a very compact rock, little liable to be acted upon by atmospheric agencies. It is chiefly obtained from Palæozoic strata, but it is found also among more recent rocks. It is used for various purposes, being split into thin slabs of small size for the roofing of houses, and into larger slabs for fitting up dairies, &c., and even for making billiard-tables, and split and polished by means of pumice for writing-slates. There are extensive quarries of roofing-slate in Wales and in the Western Highlands of Scotland, and in the Ardennes in France, some of which have been wrought for a long time, and give employment to a great number of workmen. A hard compact slate is best for roofing; that which is porous imbibes water, the freezing of which splits it in winter, whilst it affords also a soil for mosses, which soon injure the roof.

In roofing with slates, it is necessary to put on the slates in two thicknesses, so that the sloping joints may be covered by the overlap of the course above. Besides this, the third course must also cover the first by an inch or two, to prevent rain from penetrating. Slates are generally laid upon boarding, and bedded in lime, and nailed with malleable-iron nails, japanned, so as to prevent them from rusting. When large strong slates are used, they may be nailed to strong laths in place of boarding. Welsh slates are the cheapest and most generally used; but Easdale or Ballachulish slates, from the west of Scotland, are stronger and better when the roofs are liable to be injured.



SLATE-PENCILS are either cut or turned sticks of slate, or they are made by pressing moistened slate-powder until it is firm enough to be made into pencils.

SLAVE-COAST, a division of the coast of Upper Guinea Africa, lying between the rivers Volta and Lagos. See GUINEA.

SLAVERY. A slave is an individual who is the property, or at the disposal of another, who has a right to employ or treat him as he pleases. Such is the state of the slave in the most absolute sense of the term; but slavery has been subjected to innumerable limitations and modifications.

Slavery probably arose at an early period of the world's history out of the accident of capture in war. Savages, in place of massacring their captives, found it more profitable to keep them in servitude. All the ancient oriental nations of whom we have any records, including the Jews, had their slaves. The Hebrews were authorized by their law to possess slaves, not only of other races, but of their own nation. The latter were generally insolvent debtors, who had sold themselves through poverty, or thieves who lacked the means of making restitution; and the law dealt with them far more leniently than with stranger slaves. They might be redeemed; and if not redeemed, became free in the space of seven years from the beginning of their servitude; besides which, there was, every fiftieth year, a general emancipation of native slaves.

Slavery existed in ancient Greece: in the Homeric poems, it is the ordinary destiny of prisoners of war; and the practice of kidnapping slaves is also recognized—Ulysses himself narrowly escaping a fate of this kind. None of the Greek philosophers considered the condition of slavery objectionable on the score of morals. Aristotle defends its justice on the ground of a diversity of race, dividing mankind into the free and the slaves by nature; while Plato only desires that no Greeks should be made slaves. One class of Greek slaves were the descendants of an earlier and conquered race of inhabitants, who cultivated the land which their masters had appropriated, paid rent for it, and attended their masters in war. Such were the Helots in Sparta, the Penestæ in Thessaly, the Bithynians at Byzantium, &c., who were more favorably dealt with than other slaves, their condition somewhat resembling that of the serfs of the middle ages. They could not be sold out of the country, or separated from their families, and were even capable of acquiring property. Domestic slaves obtained by purchase were the unrestricted property of their owners, who could dispose of them at pleasure. In Athens, Corinth, and the other commercial states, they were very numerous, and mostly barbarians. They were employed partly in domestic service, but more as bakers, cooks, tailors, or in other trades, and in mines and manufactories; and their labor was the means by which the owner obtained profit for his outlay in their purchase. These slaves were, for the most part, purchased; but few were born in their master's family, partly from the general discouragement of the cohabitation of slaves, and partly from the small number of the female in comparison with the male slaves. An extensive traffic in slaves was carried on by the Greek colonists in Asia Minor with the interior of Asia; and another source of supply arose from the practice common among Thracian parents of selling their children. In Greece in general, and especially at Athens, slaves were mildly treated, and enjoyed a large share of legal protection. According to Demosthenes, a slave at Athens was better off than a free citizen in many other countries.

The Roman condition of slavery differed in some particulars from that of Greece. All men were considered by the Roman jurists to be free by natural law; while slavery was regarded as a state contrary to natural law, but agreeable to the law of nations, when a captive was preserved, instead of being slain (hence the name *servus*, quasi *servatus*); or agreeable to the civil law, when a free man sold himself. In earlier times, there was no restriction on the master's power of punishing or putting to death his slave; and even at a later period, when the law on this head was much modified, slaves were used with considerable rigor. The estimation in which their lives were held is illustrated by the practice of gladiatorial combats, as also by the conduct of Vedius Pollio, who, in the polite age of Augustus, flung such slaves as displeased him into his fishponds, to feed his lampreys, and on the matter being brought under the emperor's notice, was visited with no severer punishment than the destruction of his ponds. Old and useless slaves were often exposed to starve in an island of the Tiber. Under the Empire, the cruelty of masters was in some degree restrained by law. It was enacted that a man who put to death his own slave without cause should be dealt with as if the slave had been the property of another; and that if the cruelty of the master was intolerable, he might be compelled to sell the slave. A constitution of Claudius declared the killing of a slave to be murder, and it was also enacted, that in sales of slaves, parents and children, brothers and sisters, should not be separated. A slave could not contract marriage, and no legal relation between him and his children was recognized. The children of a female slave followed the status of their mother. There were various ways in which a slave might be manumitted, but the power of manumission was restricted by law. The harboring of a runaway slave was illegal. The number of slaves in Rome, originally small, was increased much by war and commerce; and the cultivation of the soil came, in the course of time, to be entirely given up to them.

During the later republic and empire, persons in good circumstances kept an immense number of slaves as personal attendants; and the possession of a numerous retinue of domestic slaves was matter of ostentation—200 being no uncommon number for one person. A multitude of slaves were also occupied in the mechanical arts and the games of the amphitheater. Originally, a slave was incapable of acquiring property, all his acquisitions belonging to his master; but when slaves came to be employed in trade, this condition was mitigated, and it became the practice to allow a slave to consider part of his gains, called his *peculium*, as his own, a stipulation being sometimes made that he should purchase his freedom with his peculium, when it amounted to a specific sum.

Though the introduction of Christianity did not do away with slavery, it tended to ameliorate the condition of the slave. Justinian did much to promote the eventual extinction of slavery; and the church excommunicated slave-owners who put their slaves to death without warrant from the judge. But the number of slaves again increased; multitudes being brought with them by the barbarian invaders, who were mostly Slavonian captives (whence our word *slave*); and in the countries which had been provinces of the empire, slavery continued long after the empire had fallen to pieces, and eventually merged into the mitigated condition known as serfdom, which prevailed all over Europe in the middle ages, and has been gradually abolished in modern times. See SERF. But though the practice of selling captives taken in war as slaves ceased in the Christian countries of Europe, a large traffic in slaves continued among Mohammedan nations, by whom Christian captives were sold in Asia and Africa; and in the early middle ages, the Venetian merchants traded largely in slaves, whom they purchased on the coast of Slavonia, to supply the slave-markets of the Saracens.

The negro slavery of modern times was a sequel to the discovery of America. Prior, however, to that event, the negroes, like other savage races, enslaved those captives in war whom they did not put to death, and a considerable trade in slaves from the coast of Guinea was carried on by the Arabs. The deportation of the Africans to the plantations and mines of the New World doubtless raised the value of the captive negro, and made slavery rather than death his common fate; while it may also have tempted the petty princes to make war on each other, for the pur-

pose of acquiring captives, and selling them. The aborigines of America having proved too weak for the work required of them, the Portuguese, who possessed a large part of the African coast, began the importation of negroes, in which they were followed by the other colonizers of the New World. The first part of the New World in which negroes were extensively used was Hayti, in St. Domingo. The aboriginal population had at first been employed in the mines; but this sort of labor was found so fatal to their constitutions that Las Casas, bishop of Chiapa, the celebrated protector of the Indians, interceded with Charles for the substitution of African slaves as a stronger race; the emperor accordingly, in 1517, authorized a large importation of negroes from the establishments of the Portuguese on the coast of Guinea. Sir John Hawkins was the first Englishman who engaged in the traffic, in which his countrymen soon largely participated, England having exported no fewer than 300,000 slaves from Africa between the years 1680 and 1700; and between 1700 and 1786, imported 610,000 into Jamaica alone. The slave-trade was attended with extreme inhumanity; the ships which transported the negroes from Africa to America were over-crowded to such an extent that a large proportion died in the passage; and the treatment of the slave after his arrival in the New World depended much on the character of his master. Legal restraints were, however, imposed in the various European settlements, to protect the slaves from injury; in the British colonies courts were instituted to hear their complaints; their condition was to a certain extent ameliorated, and the flogging of women was prohibited. But while slavery was thus legalized in the British colonies, it was at the same time the law of England (as decided in 1772 in the case of the negro Somerset), that as soon as a slave set his foot on English soil he became free; though, if he returned to his master's country, he could be reclaimed.

Before the idea of emancipation was contemplated, the efforts of the more humane portion of the public were directed towards the abolition of the traffic in slaves. In 1787, a society for the suppression of the slave-trade was formed in London, numbering Messrs. W. Dellwyn, Thomas Clarkson, and Granville Sharp among its original members. The most active parliamentary leader in the cause was Mr. William Wilberforce, whose views were seconded by Mr. Pitt. In February 1788, an order of the crown directed that an inquiry should be made by a committee of the Privy Council into the state of the slave-trade; and an act was passed to regulate the burden of slave-ships, and otherwise diminish the horrors of the middle-passage. A bill introduced by Mr. Wilberforce for putting an end to the further importation of slaves was lost in 1791. Meanwhile, our conquest of the Dutch colonies having led to a great increase in the British slave-trade, an order in council, in 1805, prohibited that traffic in the conquered colonies; and in the following year, an act was passed forbidding British subjects to take part in it, either for the supply of the conquered colonies or of foreign possessions. In the same year, a resolution moved by Mr. Fox for a total abolition next session, was carried in the Commons, and on Lord Granville's motion, adopted in the Lords; and the following year, the general abolition bill, making all slave-trade illegal after 1st January 1808, was introduced by Lord Howick (afterwards Earl Grey) in the House of Commons, was carried in both Houses, and received the royal assent on 25th March 1807.

British subjects, however, continued to carry on the trade under cover of the Spanish and Portuguese flags; the slave-ships were more crowded than ever, from the necessity of avoiding capture, and the negroes were not unfrequently thrown overboard on a pursuit. The pecuniary penalties of the act were discovered to be inadequate to put down a traffic so lucrative as to cover all losses by capture. Mr. Brougham therefore, in 1811, introduced a bill, which was carried unanimously, making the slave-trade felony, punishable with 14 years' transportation, or from three to five years' imprisonment with hard labor. An act of 1824 declared it piracy, and as such, a capital crime, if committed within the Admiralty jurisdiction; and the statute of 1837, mitigating the criminal code, left it punishable with transportation for life. Among the philanthropic projects due to the exertions of the Anti-slavery Society was the establishment of the colony of Sierra Leone, on the coast of Africa, which had been formed by the British government in 1787, in order to show the possibility of obtaining colonial produce without slave-labor, and after the abolition of the slave-trade, became a settlement for the negroes captured by British cruisers.

The United States of America abolished the slave-trade immediately after Great Britain, and the same was in the course of time done by the South American republics of Venezuela, Chili, and Buenos Ayres, by Sweden, Denmark, Holland, and during the Hundred Days after Napoleon's return from Elba, by France. Great Britain, at the peace, exerted her influence to induce other foreign powers to adopt a similar policy; and eventually nearly all the states of Europe have passed laws or entered into treaties prohibiting the traffic. The accession of Portugal and Spain to the principle of abolition was obtained by treaties of date 1815 and 1817; and by a convention concluded with Brazil in 1826, it was declared piratical for the subjects of that country to be engaged in the slave-trade after 1830. By the conventions with France of 1831 and 1833, to which nearly all the maritime powers of Europe have since acceded, a mutual right of search was stipulated within certain seas, for the purpose of suppressing this traffic. The provisions of these treaties were further extended in 1841 by the Quintuple Treaty between the five great European powers, subsequently ratified by all of them except France. The Ashburton treaty of 1842 with the United States provided for the maintenance by each country of a squadron on the African coast; and in 1845, a joint co-operation of the naval forces of England and France was substituted for the mutual right of search.

The limitation of the supply of negroes naturally led, among other good results, to a greater attention on the part of the masters to the condition of their slaves. But the attention of British philanthropists was next directed towards doing away with slavery altogether in our colonies. Societies were formed with this end, an agitation was set on foot, and attempts were made, for some time without success, to press the subject of emancipation on the House of Commons. At length, in 1833, a ministerial proposition for emancipation was introduced by Mr. Stanley, then Colonial Secretary, and an emancipation bill passed both Houses, and obtained the royal assent, 28th August 1833. This act, while it gave freedom to the slaves throughout all the British colonies, at the same time awarded an indemnification to the slave-owners of £20,000,000. Slavery was to cease on 1st August 1834; but the slaves were for a certain duration of time, to be apprenticed laborers to their former owners. Objections being raised to the apprenticeship, its duration was shortened, and the complete enfranchisement took place in 1838.

The French emancipated their negroes in 1848; as did most of the new republics of South America at the time of the revolution; while the Dutch slaves had freedom conferred on them in 1863. In Hayti, slavery ceased as far back as 1791, its abolition having been one of the results of the negro insurrection of that year. Slavery still exists in the Spanish and Portuguese colonies, but recent acts have been passed for its abolition. In Brazil, a law for the gradual emancipation of slaves was passed in 1871. It enacts that from that date children born of slave women shall be free; while, at the same time, they are bound to serve the owners of their mothers as apprentices for twenty-one years. A recent treaty between Great Britain and the Sultan of Zanzibar secures, in promise, the speedy abolition of the slave-trade on the opposite eastern coast of Africa. The expedition of Sir Samuel Baker, in 1873, was announced as having put an end to the slave-trade to the south of Egypt, as far as the equator. How far the Khedive was sincere in coupling this object with the conquest of the Nile regions is doubtful; and it is certain that most of his officers, and an army of slave-hunters, are bent on defeating the attempt. In 1874, the British governor at the Gold Coast, where domestic slavery still existed, announced that thenceforth no person could be sold as a slave in the protectorate, or removed from it for that purpose.

In presence of the statement in the 'Declaration of Independence,' that 'all men are born free and equal, and possess equal and inalienable rights to life, liberty, and the pursuit of happiness,' the colonies which threw off the British yoke numbered several hundred thousand negro slaves, whose condition of slavery was expressly recognized in the constitution of the United States, as ratified in 1788, provision being there made for the rendition of fugitive slaves, a subject the regulation of which was delegated to the federal government, slavery being otherwise left to be governed by the laws of the states where it existed. Slavery established itself firmly in the southern states, where negro labor was required for the cultivation of sugar and cotton; and after the limitation of the supply from Africa, the breeding of slaves went on to a large extent in Maryland and Virginia for the supply of the other states of the south. The different position of the northern and southern states regarding slavery, combined with other causes to engender that diversity of feeling and interest between north and south, out of which arose the civil war. The politicians of the north, however, except a small section, by no means advocated the abolition of slavery where it already existed; they only objected to its extension to new territories. The increased consumption of cotton led to an increased demand for slave-labor; and in 1820, when Missouri was admitted to the Union as a slave state, a compromise was entered into by which slavery was legalized to the south, but prohibited to the north of 36° 30′ N. lat. (see MASON AND DIXON'S LINE).

California, though partly lying south of that geographical line, was admitted as a free state, the southern party obtaining in compensation the boon of an amendment of the fugitive Slave Law, making it penal to harbor runaway slaves or aid in their escape. A reaction against the policy of the south, and Mr. Lincoln's elec-

tion as President, were the signals for a long contemplated secession of the southern states, and the bloody war which ended in the overthrow of the principle of state-sovereignty and the consolidation of the Union. In the course of the war, many negroes were emancipated; and on 22d September 1862, Mr. Lincoln issued a proclamation declaring all the negroes of secession masters who should not have returned to the Union before 1st January 1863, to be free. In January 1865, congress finally voted for an amendment to the constitution, abolishing slavery; and by the end of the year this had been approved by an overwhelming majority of the state legislatures.

SLAVES, or SLAVONIANS (native name *Slowene* or *Slowane*, derived by some from *Slawa*, fame, but better from *Slowo*, a word; thus meaning 'speaking' or 'articulate,' as distinguished from other nations, whom they called Niemetz, or 'Mutes'), the general name of a group of nations belonging to the Aryan family, whose settlements extend from the Elbe to Kamtchatka, and from the Frozen Sea to Ragusa on the Adriatic, the whole of Eastern Europe being almost exclusively occupied by them. They were settled in these regions before the dawn of history, and are comprehended by ancient writers under the designations of Sarmatians and Scythians. The original names of the Slavic tribes seem to have been Winds or Wends (*Venedi*) and Serbs. The former of these names occurs among the Roman writers, and later, in Jornandes, in connection with the commercial peoples of the Baltic Sea; the latter is spoken of by Procopius as the ancient name common to the whole Slavic stock.

The earliest historical notices extant represent the S. as having their chief settlements about the Carpathians, from which they spread northward to the Baltic, westward as far as the Elbe and the Saal, and later after the overthrow of the kingdom of the Huns, southward beyond the Danube, and over the whole peninsula between the Adriatic and the Black Sea. These migrations ceased in the 7th c.; the division of the Slavic stock into separate branches became now more complete, and gradually they began to form into independent states. The various sections of the stock may be divided into two groups, the south-eastern and the western; the first comprehends—(1), Russians; (2), Bulgarians; (3), Illyrians (Serbs, Croats, Winds): the second—(1), Lechs (Poles, Silesians, Pomeranians); (2), Czechs or Bohemians (Czechs, Moravians, Slovaks); (3), Polabians, comprising the Slavic tribes of N. Germany, who are fast disappearing, by being absorbed in the Teutonic population. With the exception of Russia and, since the Berlin Congress of 1878, of Servia and Montenegro, the once numerous Slavic kingdoms (Bohemia, Bulgaria, Moravia, Poland, &c.) have lost their independent sovereignty, and been incorporated in other states, chiefly Turkey, Austria, Prussia, and Saxony. The Polabians never attained any distinct political footing. The whole of the Slavic populations are estimated at upwards of 80 millions.

The S. are represented by ancient writers as an industrious race, living by agriculture and the rearing of flocks and herds; as hospitable and peaceful, and making war only in defence. The feeling of nationality was strong among them. The government had a patriarchal basis, and chiefs or princes were chosen by assemblies. But contact with the feudal institutions of the Roman-German empire gradually altered this primitive constitution; the Slavic princes strove after unlimited power, like that of the emperors; and the chiefs sought to dominate over the people, like the feudal nobility. In the course of the 11th, 12th, and 13th centuries, nobility became a hereditary privilege throughout the Slavic states. The worst kind of feudalism fairly took root, and the people sank into the condition of serfs. Between them and the nobles there was no third or middle class, as the peculiar privileges of the nobility prevented the growth of cities. See SERF, RUSSIA.

The *religion* of the ancient S., like that of the Teutonic nations, seems to have been, in many of its features at least, a kind of nature-worship; not, however, without the idea of a One supreme power, to whom the other agencies were subordinate. From this, some authorities infer that the system was originally a monotheism, which in process of time had become obscured and confused by the infusion of foreign elements, and thus degenerated into polytheism, and finally pantheism. The chief deity, whose worship seems to have been common to all the Slavic tribes, was Swiatowit, with whom were associated on a nearer footing of equality than the other gods, Perun and Radegast—if, indeed, these three names do not merely denote different personations or manifestations of the same power. In this trinity, Swiatowit is considered as most analogous to Mars and Zeus, Perun to Jupiter and Thor, and Radegast to Mercury and Odin.

Of the numerous gods of an inferior order, we may name Prowe, god of justice; Prija (= Freya), Venus; Bjelbog, the White god, and Cernobog, the Black god; together with multitudes of demons and spirits good and bad. The images of the Slavic divinities (a stone statue of Swiatowit was in recent times discovered in Eastern Galicia) had a striking resemblance to those of India. Swiatowit had four heads, Rugewit (the god of war) had seven faces, and Perun four, and so on. The S. seem to have been not without some crude notion of existence and retribution after death. Worship was performed in groves and temples, cattle and fruits being offered by the priests, whose office must have been originally performed by the head of the family or chieftain, as the common name for priest and prince (*kniez*) shows.—The eastern S. received Christianity from Byzantium in the 9th c., through the instrumentality of Cyril (q. v.) and Methodeus; the western, from Rome and Germany.—PANSLAVISM is the subject of an article (q. v.). See Schafarik, *Slaw. Alterthümer*.

SLA'VIC LANGUAGE AND LITERATURE. The term Slavic, as applied to language or race, is a generic name (like Celtic or Teutonic) for a group of kindred languages and peoples belonging to the great Indo-Germanic or Aryan family. In its roots and structure, the Slavic language exhibits a remarkable similarity to Sanscrit, but has become European, so to speak, in the course of a long literary development, begun *before* that of any of the other European families. Its peculiarities are quite marked. The leading characteristics of the Slavic tongues are the completeness of their system of declensions, the want of articles, the absence of pronouns in the conjugation of the verb, pure vowel-endings, the fixed quantity of the syllables, the free construction of sentences, and the richness of their vocabulary. The earliest dialect of Slavic that received a literary culture was the 'Old Bulgarian,' better known as the 'Church Slavic,' which, however, failed to become the literary vehicle for all the Slavic peoples, inasmuch as the special dialect of each gradually acquired a literature of its own. Altogether, writers reckon eight distinct extant dialects of Slavic: 1. The 'New Bulgarian;' 2. The Russian; 3. The Servian or Illyrian; 4. The Polish; 5. The Bohemian; 6. The Slovak; 7. The Wendic; 8. The Polabic. Such of these as merit special treatment have received it.—See BOHEMIAN LANGUAGE AND LITERATURE, POLISH LANGUAGE AND LITERATURE, RUSSIAN LANGUAGE AND LITERATURE, SERVIAN LANGUAGE AND LITERATURE.—In regard to Slavic literature, considering the articles just mentioned, it is only necessary to state that at present the Russian branch of the Slavic is the richest in the number of its published works; but as regards literary merit, the Polish ranks first, having cultivated with great success almost all sorts of literature, and possessing in particular a very exquisite poetry. The Bohemian and Servian literatures both contain many fine and distinctively original productions, worthy of being more widely known than they are.—See the works of Schafarik, Eichhoff (in French), Mickiewicz, Talvi (Eng. transl.), Krek and Miklosich (*Vergl. Grammatik*, new ed. 1876).

SLAVO'NIA, a province of Austria, lying east of Croatia (q. v.), with which it is now politically united. It is bounded on the N. by the Drave, on the E. by the Danube, on the S. by the long strip of marsh-land known as the Slavonian Military Frontier, which stretches between it and the Save. Area of the kingdom of Croatia (q. v.) and Slavonia, 8840 sq. m.; pop. (1880) 1,191,845. The greater part of the surface of S. consists partly of eminences clothed with vines and fruit-trees, and partly of fertile and swampy plains. The mountains are rich in coal, marble, and mineral springs. The principal products are all sorts of grain, particularly maize and wheat, leguminous plants, and fruit in abundance, apples, pears, plums, walnuts, chestnuts, melons, wine, &c. There is little manufacturing industry in Slavonia.—The inhabitants of S. belong to the Slavic family (see SLAVES), and call their land Slavonska; themselves Slavonaz. They speak the so-called Illyrian or Servian tongue. See SERVIAN LANGUAGE AND LITERATURE. The Slavonians proper are a handsome, tall, and slender race. The prevailing form of religion is the Roman Catholic, but the non-united Greek Church also numbers many adherents. Education is still in a backward state. Capital of the country, Eszék (q. v.).

SLEA'FORD, a town of Lincolnshire, England, on the right bank of the Slea, a branch of the Witham, 17 miles south-south-east from Lincoln, and 52 feet above the level of the sea. It is a well-built and well-paved town, and has a fine church, built in the 13th century. Pop. (1871) 3592.

SLEEP. This term is employed to designate that state of suspension of the sensory and motor functions which appears to alternate in all animals with the active condition of those functions, and which may be made to give place to it by the agency of appropriate impressions upon the sensory nerves. This definition, which we have borrowed from Dr. Carpenter's article on 'Sleep' in Todd's *Cyclopædia of Anatomy and Physiology*, may seem somewhat complex, but cannot be simplified without rendering it less stringent. The necessity for sleep arises from the fact, that the exercise of the animal functions is in itself destructive of the tissues of the organs which minister to them, so that if the waste produced by their action were not duly repaired, they would speedily become unfit for further use; and it is on the nutritive

regeneration of the tissues which takes place during true healthy sleep that its refreshing power depends. While the sensory and motor functions are suspended during the condition we designate as sleep, the organic functions are uninterruptedly carried on, the respiratory, cardiac, and peristaltic movements proceeding with equal uniformity during the sleeping and waking states.

There can be no doubt that the state of sleep is one to which there is a periodical tendency, and that this disposition is so arranged as to correspond in its recurrence with the diurnal revolution of the earth. Although in man and most animals night is, from its darkness and silence, the natural period for repose, yet there are numerous exceptions to the rule. For example, amongst lepidopterous insects, butterflies are active during the day, hawk-moths during the twilight, and moths during the night. Amongst birds, the goatsucker, or night-jar, and the owls, are nocturnal, and, as a general rule, the same is the case with carniverous animals. The causes of sleep may be divided into the direct and the predisposing. The direct cause of sleep is that feeling of exhaustion or fatigue which is usually experienced when the waking activity has continued during a considerable portion of the twenty-four hours—a feeling that the brain requires repose; and, in fact, unless the brain be in an abnormal condition, sleep will at last supervene, from the absolute inability of that organ to sustain any further demands upon its energy.

Among the predisposing causes which favor the access of sleep, we must especially notice 'the *absence* of sensorial impressions; thus, darkness and silence usually promote repose; and the cessation of the sense of muscular effort which usually takes place when we assume a position that is sustained without it, is no less conducive to slumber.'—Carpenter's *Human Physiology*, 6th ed. 1864, p. 592. On the other hand, persons accustomed to live where there is a continuous noise, as in the neighborhood of mills or forges, often cannot sleep if the noise is suspended. These cases, however, probably fall within the next general predisposing cause —namely, the *monotonous repetition* of sensorial impressions. Thus, the droning voice of an unimpressive reader or preacher, the gentle ripple of the ocean, the hum of bees, the rustling of foliage, and similar monotonous impressions on the auditory nerves, are usually provocative of sleep. In these and similar cases, the influence of the impressions is exerted in withdrawing the mind from the consciousness of its own operations, and in suspending the directing power of the will; and this is the case, says Dr. Carpenter, 'even when the attention is, in the first instance, *voluntarily* directed to them, as in some of the plans which have been recommended for the induction of sleep, when there exists no spontaneous disposition to it. In other methods, the attention is fixed upon some internal train of thought, which, when once set going, may be carried on automatically, such as counting numbers, or repeating a Greek verb. In either case, when the sensorial consciousness has been once steadily fixed, the monotony of the impression (whether received from the organ of sense or from the cerebrum) tends to retain it there; so that the will abandons, as it were, all control over the operations of the mind, and allows it to yield itself up to the soporific influence. This last method is peculiarly effectual when the restlessness is dependent upon some mental agitation, provided that the will has power to withdraw the thoughts from the exciting subject, and to reduce them to the tranquillizing state of a mere mechanical repetition.'

The access of sleep is sometimes quite sudden, the individual passing at once from a state of complete mental activity to one of entire torpor. More generally, however, it is gradual, the mind while remaining poised, as it were, between sleep and the opposite condition being 'pervaded by a strange confusion which almost amounts to wild delirium; the ideas dissolve their connection with it one by one; and its own essence becomes so vague and diluted that it melts away in the nothingness of slumber.'—Macnish, *Philosophy of Sleep*, p. 21. The amount of sleep required by man is affected by so many conditions (amongst which must be especially mentioned *age*, *temperament*, *habits*, and previous exhaustion), that no general rule can be laid down on the subject. The condition of the *fœtus* may be regarded as one of continuous slumber: on its first entrance into the world, the infant passes most of its time in sleep, and this is particularly the case in children prematurely born, such children seeming only to awake for the purpose of receiving food. During the whole period of growth, in which it is necessary that the *constructive* operations of the body should preponderate over the *destructive* processes, an excess of sleep is required; and by the time that adult age has been attained, and the constructive and destructive processes balance each other, the necessary amount of sleep has gradually fallen to about one-third or less of the diurnal cycle. In very old age, again, in consequence of the deficient energy of the nutritive process, a larger amount of sleep is required. With regard to the influence of temperature, it is observed that a plethoric habit of body usually predisposes to sleep, while thin wiry people of a nervous temperament require comparatively little sleep.

Persons of lymphatic temperament are usually great sleepers, but this is probably due, as Dr. Carpenter suggests, to the fact, that 'through the dulness of their perceptions they are less easily kept awake by sensorial or mental excitement' than persons of a happier temperament. The influence of habit is by no means inconsiderable on the amount of sleep required by individuals, and this influence may be brought to act on the protraction as well as the abbreviation of the usual period: as extreme examples, we may mention that General Eliott, celebrated for his defence of Gibraltar, did not sleep more than four hours out of the twenty-four (which is probably the smallest allowance for rest compatible with a life of vigorous exertion); while Dr. Reid, the metaphysician, could take as much food, and afterwards as much sleep, as were sufficient for two days. Moreover, the influence of habit in producing an aptitude for repose, or a readiness to wake at particular periods, is well known. The sleep of soldiers during a siege, of sailors or others who must take their rest as they best can, will often come on at command; nothing more being necessary to induce it than to assume a recumbent, or, at all events, an easy position, and to close the eyes. Thus, Captain Barclay, in his celebrated match, in which he walked 1000 miles in 1000 successive hours, very soon got into the habit of falling asleep the moment he lay down.

The condition of the great nervous centers during sleep is a subject of much interest, on which considerable light was some time ago thrown by the observations of Mr. Durham. These observations were made on a dog from which a portion of bone about as large as a shilling was removed from the parietal region of the skull, and the subjacent dura mater cut away so as to expose the brain; and Mr. Durham draws the following conclusions from them: 1. Pressure of distended veins upon the brain is not, as is generally believed, the cause of sleep, for during sleep the veins are *not* distended.

2. During sleep, the brain is in a comparatively bloodless condition; and the blood in the encephalic vessels is not only diminished in quantity, but moves with diminished rapidity; and this is corroborated by the observations of Dr. J. Hughlings Jackson on the ophthalmoscopic condition of the retina during sleep, the optic disc being then whiter, the arteries smaller, and the retina generally more anæmic than in the waking state. 3. The condition of the cerebral circulation during sleep is, from physical causes, that which is most favorable to the nutrition of the brain tissue.*

This article would be imperfect without a brief reference to the conditions in which there is either an excess or a deficiency of sleep. There are numerous instances on record in which sleep has been continuously prolonged for weeks, or even months. Dr. Carpenter refers to two such cases, namely those of Samuel Chilton (*Phil. Trans.* 1694) and Mary Lyall (*Trans. Roy. Soc. Edin.* 1818). Blanchet, a French physician, has recently recorded three cases of what he terms 'constitutional lethargic slumber' in the *Comptes Rendus*, 1864. In one of these cases, the patient, a lady aged 24 years, who had slept for 40 days when she was 18 years of age, and 50 days when she was 20, at length had a sleep of nearly a year, viz., from Easter Sunday 1862 to March 1863. During this period, a false front tooth was removed in order to feed her with milk and soup, her only food. She was motionless and insensible. The pulse was low, the breathing scarcely perceptible, there were no evacuations, and she showed no signs of leanness, her complexion remaining florid and healthy. In such cases as these, it is not a prolongation of healthy natural sleep that is present, but a condition of hysteric coma.

Again, there are certain states of the nervous system in which there is either an entire absence of sleep (and this may continue for many days, or even weeks) or incomplete sleeplessness. Complete sleeplessness is often a most important symptom of disease. It frequently accompanies certain forms of continued fever, inflammatory affections of the brain, the eruptive fevers, &c., and when it continues for many days and nights, delirium, followed by stupor, is very apt to supervene. When the wakefulness is unattended by any disorder sufficient to account for it, some serious disease of the brain is most probably impending, such as palsy, apoplexy, or insanity. Incomplete or partial sleeplessness is a symptom of far less grave import. It is of frequent occurrence in persons whose minds are much engaged, or whose occupations subject them to great mental exertion or to the vicissitudes of fortune. It is, moreover, a symptom of many chronic diseases, as gout, chronic rheumatism, skin-diseases, disorders of the urinary organs, dyspepsia, hysterica, &c. It may also be excited by certain beverages and articles of diet; thus green tea and strong coffee often occasion wakefulness, and a full meal of animal food late in the day often disturbs the sleep of persons accustomed to dine at an earlier hour.

In the treatment of sleeplessness, or *insomnia*, as it is usually termed by medical writers, the first indication is to remove the cause which occasions it, and 'more particularly to correct a close

* See Dr. Cappie's theory as to the balance of the distribution of blood within the cranium, in *The Causation of Sleep* (2d ed. 1883).

or contaminated air; to reduce the temperature of the apartment when it is high, and the quantity and warmth of the bedclothes; to remove all the excitants to the senses; to abstract the mind from all exciting, harassing, or engaging thoughts; and to remove or counteract the morbid conditions of which this is a symptom or prominent consequence.'—Copland's *Dictionary of Medicine*, art. 'Sleep and Sleeplessness.'

A careful regulation of the secretions, by the due use of purgatives and alteratives, will often remove this symptom; and recourse should not be had to anodynes and narcotics until morbid secretions and fæcal accumulations have been completely got rid of. But these medicines are of great service when the system is thus prepared for their reception. The choice of the individual drug or combination of drugs must be dependent upon the peculiarities of the case, but, as a general rule, there is no more serviceable narcotic mixture for an adult than 25 or 30 minims of the solution of hydrochlorate of morphia (of the British Pharmacopœia), and 10 minims of chloric ether, taken in half a wine-glassful of water: medicines of this class should, however, never be resorted to without the advice of a physician.

SLEEP OF PLANTS, one of the phenomena of Irritability (q. v.) in plants. Light acts on plants as a powerful stimulus, essential to their active and healthful vegetation. When it is withdrawn, the flowers of many plants close, and the greater number show a tendency to it, whilst leaves more or less decidedly incline to fold themselves up. The leaf-stalk also generally hangs down more or less, although in some plants it is more erect during sleep. The sleep of plants, however, is not always nocturnal. The flowers of some open and close at particular hours of the day. Thus, the crocus is a morning flower, and closes soon after mid-day; whilst some flowers expand only in the evening or during the night. Their hours of vegetative rest are probably as essential to the health of plants as those of sleep are to animals. It was Linnæus who first observed the sleep of plants in watching the progress of some plants of *lotus*, the seeds of which he had sown.

SLEEPERS, timbers laid *asleep* or resting along their whole length. They are chiefly used along the top of dwarf-walls for the support of the timbers of the ground floor of houses.—The timbers supporting railway rails, and laid at right angles to them across the railway, are also called sleepers.

SLE'SVIG, a duchy known till the 14th c. as South Jutland, formed part of the Danish dominions till 1864, when it fell into the hands of the Austrian and Prussian sovereigns. In terms of the treaty of 1867, it was incorporated with Prussia. The population in 1864 was 406,486. Within its old recognized limits, it was bounded on the N. by Jutland; on the E. by the Little Belt and the Baltic; on the W. by the German Ocean; and on the S. by Holstein, from which it was divided by the Eyder and the Kiel Canal. The area was 3492 sq. miles. The country consists in its eastern and central parts of a gently undulating plain, deeply indented with fiords and streams; and on its western boundary of flat marshy tracts of ground, which require to be protected from the encroachments of the sea by numerous dams.

The numerous islands which skirt the west coast of S. have probably, at some not very remote period, formed part of the mainland, for navigation is so seriously impeded by the sand-banks, that this coast is now accessible for ships by only three passages. The cluster of small islands known as the Halligers, which lie, unprotected by dams, in the midst of these submerged sand-tracts, are so constantly exposed to the action of waves and storms, that the inhabitants are compelled to raise their houses on piles. On the eastern coast of S. lie the islands of Alsen, Aroe, and Femern, where the principal bays and inlets are the Hadersley and Aabenrade Fiords, opening into the Little Belt; the Flensborg Fiord, the Slie, the Eckernforde Fiord, and the Kieler Fiord, which formed the ancient boundary between S. and Holstein on the S.-E., while the Eyder completed it on the S.-W. The principal branches of industry are agriculture, the rearing of cattle, fishing, and ship-building.

The Slie is the chief seat of the herring and salmon fisheries, which, although still of some importance, are very inferior to those of the middle ages, when, according to the Danish historian, Saxo Grammaticus, herrings were so plentiful in the Belts and Cattegat, that they could be caught with the bare hands. The chief towns of S. are Flensborg (q. v.), Slesvig, now capital of a Prussian province, a very ancient city, and formerly the key of Denmark (pop. about 16,000); Hadersley, Husum, and Tonder. In the south, and partly in Holstein, Rendsborg (pop. 13,000). S. has 800 schools. With regard to the language spoken by the mixed population of the duchy, it may be asserted that rather more than the half speak Danish; and of the remainder, about 30,000 persons who belong to the islands on the western coast, which once formed part of the old province of North Friesland, still use the Frisic language, the rest of the inhabitants using either Low or High German. The original Danish element of S. has remained purest in the northern half of the duchy; while in the southern parts, where the inhabitants are naturally brought much in contact with Holstein, they have of late years adopted the views, tastes, and language of their German neighbors. The Lutheran is the established religion of Slesvig.

In accordance with the conditions stipulated in the treaty of Vienna, August 1864, by which the duchies of Holstein and S. were ceded to Austria and Prussia, the island of Aroe and other districts of S., measuring about 115 sq. m., were to be reunited to Denmark; while the latter power was to give in exchange a territory of about 130 sq. m., which, although situated within the boundary of S., had hitherto been under the jurisdiction of Jutland.

S., which forms part of the ancient Cimbrian Peninsula, has from the earliest period been a debatable land between Danes and Germans; and according to the authorities of the latter, it was anciently included in the Marches of the empire, having been incorporated by Henry the Fowler in 930, and reorganized by Otho I., when in 948 the latter erected bishops' sees in Aarhuus, Ribe, and Slesvig. In 1027, the Danish king Knud (our Canute) obtained from Conrad II. the recognition of the independence of S., which was declared to belong unconditionally to Denmark, and thenceforth given as a Danish fief of the crown to the younger sons of the regal house. In 1232, King Valdemar Seir, whose father, Prince Knud Laward, had ruled ably over the duchy, gave S.—which was then, and for some time later, known as South Jutland—to his younger son Abel. The exact terms of the donation became a subject of dispute during the successive reigns of Valdemar's sons, Eric, Abel, and Christopher, and began the long course of civil wars and family feuds which are associated with this much-contested territory. Abel, and his sons after him, backed by their kinsmen, the Counts of Holstein, maintained that Valdemar had given the duchy as an hereditary, inalienable, and indivisible fief; while, on the part of the Danish crown, it was contested that South Jutland was merely a *precarious* fief, which might be recalled at the pleasure of the sovereign. Its vicinity to Holstein tended to keep up the feuds, to which the vexed question of its mode of tenure had given occasion, and which, in fact, only ceased when the resources of the conflicting parties were exhausted, although the bitterness and ill-will with which they were fed seemed to know no intermission. The following brief summary gives the skeleton of the leading events of the history of S. from the dawn of its troubles till the final outbreak in 1848, when, by the influence of the neighboring Holstein nobles, the Germanized great landed proprietors of S. entered upon the course of armed opposition to the mother-country, which has culminated at the present moment in the forcible separation from the Danish crown of the duchy of S., and its imminent incorporation in the Prussian monarchy.

In 1386, Queen Margaret (q. v.) gave S. in fief to Gerhard, Duke of Holstein; and on the extinction of his male heirs in 1459, it virtually lapsed to the crown, with which it was united in 1460 under the rule of Christian I. (the founder of the Oldenburg line), by a mode disastrous to the integrity of the Danish monarchy. See DENMARK. After frequent division among the younger members of the royal House, which gave rise to a great number of collateral lines of the Oldenburg family (of which the Glucksburg-Sonderborg and the Augustenburg are, with the exception of the imperial House of Russia and the ducal House of Oldenburg, the chief representatives), the ducal portions of S. were inalienably incorporated with the crown of Denmark under King Frederick IV. in 1721. This act, which had the guarantee of the great powers, had resulted directly from the treasonable attitude maintained in the previous wars with Sweden by the Holstein-Gottorp princes of S., and was ratified by Russia and Sweden, no less than by England and France. The different orders of the duchy took the oaths of allegiance for themselves and their heirs, the S. arms were quartered with those of Denmark Proper, and the duchy was included with the latter in one common mode of administration. In 1848, the revolutionary movement of continental Europe fanned the flame of discontent in the duchies into a blaze, and the upper classes of S., who had in the course of time become strongly imbued with the German tendencies of the Holstein nobles, with whom they fraternized, joined the latter in open armed rebellion under the chief leadership of the princes of Augustenburg. The Germanized S. nobles, influenced by the principles of hatred to Denmark, which had long been gathering strength in the university of Kiel, refused to admit the difference between their relations to the crown and those of the Holsteiners, with whom they demanded to be indissolubly associated in separate legislative and executive chambers.

The king refused to separate S. from the monarchy; the irritation increased on both sides; the royal troops appeared in the duchies to restore order; the S.-Holstein army, whose ranks were principally filled by German volunteers, took the field, aided by the confederate forces sent by the Diet to co-operate with the Holsteiners. The troubles by which the German states were

threa ened at home led, after a few indecisive engagements had been fought, to the withdrawal of the confederate armies, and Prussia having made a special treaty of peace (after a preliminary truce with Denmark), the duchies were left to themselves, and the royal authority re-established, on the understanding that the king should submit a new form of constitution for Holstein and S. to the Diet, on account of the former being a member of the Confederation; S. being in the meanwhile put under a provisional government of Danish, Prussian, and English commissioners. By the peace with Prussia, it was solemnly guaranteed that all old treaties, including that of 1721, should be maintained in regard to Denmark; and in 1851, Austria threw an army into the duchies to aid Denmark in supporting her authority, and in dissolving the joint S. and Holstein assembly. On the death of Frederick VII. in 1863, Prince Christian of Glucksburg (see DENMARK), having ascended the throne as Christian IX., king of Denmark, Prince Frederick of Augustenburg called upon the S.-Holstein authorities to refuse the oath of allegiance to the new king, and to acknowledge himself as the rightful duke of S.-Holstein, basing his claims on his descent from the legitimate and elder male line of the House of Oldenburg. This appeal was responded to by 25 members of the Holstein Diet, who, on behalf of their own duchy and of S., petitioned the German Diet to recognize the validity of the claims of the Augustenburg line, and to pronounce the London protocol of the act of succession devoid of force.

The Prince, by this step, set at nought the family compact by which his father, uncle, and himself, for themselves and their heirs, had, at the close of the war of 1848, accepted a sum of money as full indemnity for all claims on the Danish territories, and had been allowed on that condition to evade all further consequences of the open rebellion in which they had stood against the throne. In the meanwhile, the fundamental law of November 1863 for the kingdom of Denmark and the duchy of S., which had passed the Rigsrad, and received the late king's signature shortly before his death, was published, together with a manifesto of Christian IX., stating his intention in regard to Holstein and Lauenburg. The Diet, without committing itself to uphold the Augustenburg claims, put a confederate execution into Holstein; the Danish troops were withdrawn into S.; and on the 6th January 1864, the Holstein towns did homage to the duke; while a Federal commission suppressed the provisional Holstein government, which had exercised its powers since 1862, and established a ducal government at Kiel. The Austrians and Prussians, professing to act for the Diet, summoned the Danish king to withdraw the constitution of November within 48 hours; in reply to which the Danish government demanded a term of six weeks to convoke the Rigsrad, without whose sanction no constitutional change could be adopted. The demand was rejected, and the Austro-Prussian army entered Holstein, and hostilities commenced. For ten weeks the Danes made a gallant stand against their enemy, whose enormous superiority in strength of numbers, and in the efficiency of their artillery and small-arms, made their final victory the inevitable rather than the glorious result of the campaign. The Danes were compelled to suspend hostilities, and to submit to the terms dictated by their conquerors.

A conference was held at Vienna, and after protracted negotiations, Denmark was constrained to accept peace (August 1864), on the hard terms of ceding to Austria and Prussia Holstein, S., and Lauenburg, on the ground that the indivisibility of the two duchies must be firmly established for the German fatherland by these two great powers. Following upon this, Duke Frederick of Augustenburg was in turn the favored and the rejected candidate for the throne of the new state of S.-Holstein. The upper classes in small numbers in S., in Holstein almost unanimously, were in favor of his claims, while the burgher and lower classes of S. appeared equally unanimous in regretting their severance from Denmark; and the decidedly expressed wishes of the Holstein party, backed by the lesser German states, to have the duke as their sovereign, the protests and counter-protests of the Diet and of foreign powers, all resulted in an announcement by Austria and Prussia, that according to the evidence of the commission appointed to examine the merits of the various claims of Denmark, Augustenburg, and Oldenburg to the duchies, Christian IX. was by right of succession the undoubted possessor, and that from him the duchies had passed by right of victory to Austria and Prussia. Prussia sought to annex these duchies to her dominions, and offered Austria pecuniary compensation for her assistance in the war. On the other hand, Austria advocated the independence of the duchies. Neither country would yield, and the dispute ultimately resulted in the war of 1866. According to a treaty concluded in 1867, Austria abandoned her claims in favor of Prussia, but stipulated that a part of S. should be restored to Denmark. This stipulation, however, has never been given effect to. See GERMAMY. The Prussian province of Schleswig-Holstein, formed out of the duchies of Slesvig and Holstein, has an area of 7190 square miles, and a pop. of (1880) 1,127,149.

SLI'CKENSIDES are the smooth and polished, and generally glazed surfaces of flaws in rocks. They are considered to have been produced by the friction of the two surfaces during some movement of the rock. But the two surfaces of the flaw are almost always so uneven that it is impossible to conceive that they could have rubbed against each other; besides, the flaws are generally very small, and the true slickenside is always confined to a single stratum, never passing into the bed above or below. We believe they are the castings of liquids or gases confined in the bed, and subjected to great pressure, and are similar in origin to the glazed cavities produced by gases in slags, or, to use a very familiar illustration, by the compressed steam in breakfast rolls.

SLIDING RULE, an instrument invented by the Rev. William Oughtred, an English divine and mathematician, for the purpose of solving arithmetical problems mechanically, consists of three pieces of wood, of which two are fastened together by slips of brass at a sufficient distance from each other to permit of a third sliding between them. The size of instrument which best combines convenience with accuracy is one about 2 feet long, 2 inches broad, and ¼ inch thick. One side of the rule has the following scales marked on it in order: a line of tenths of inches, of equal parts divided into tenths and hundredths of feet; three lines of numbers, each line consisting of the numbers from 1 to 10 twice repeated; a line of sine rhumbs (logarithmic sines of each quarter-point of the compass); a line of meridional parts; and a line of equal parts. Of these, two of the lines of numbers are on the middle piece or *slider*. On the other side are—two lines of *natural scales*, including sines, secants, tangents, equal parts, &c.; two line of logarithmic sines, two lines of logarithmic tangents, a third line of logarithmic sines, and a line of versed sines. Of these, one line of logarithmic sines and one of tangents are upon the slider. The scale in most common use is that of numbers, and a description of the way in which it is used will give a key to the whole working of the instrument.

It is necessary, however, to notice as a preliminary, that the scale of numbers is not evenly divided, as in this case only addition and subtraction could be performed, but is divided in proportion, not to the numbers, but to their logarithms, so that 3, whose logarithm is very nearly the half of that of 10, stands almost halfway between 1 and 10; and similarly of the other numbers. All questions of numerical proportion can thus be easily worked by means of the line of numbers on the slider, and the adjacent and corresponding one on the fixed part of the rule. To find a fourth proportional to three given numbers, we place the first term (on the slider) opposite to the second term (on the fixed scale), and opposite the third term (on the slider) is the fourth or number required (on the scale). Multiplication is performed by making 1 the first term of a proportion, and division by making it the second or third. The other scales marked on the rule are useful in the solution of trigonometrical, geographical, and nautical problems, and the results obtained are much more accurate than one at first sight would believe. Sliding rules of circular form have been made by the French, but they are not in any way preferable to the ordinary straight form.

SLIDING SCALE, a provision in some of the statutory restrictions formerly in force on the trade in corn, by which, in order to encourage importation when prices were high, and discourage it when low, the import duty was diminished as the price rose, and at famine-prices grain came in duty free. By the act of 1828, wheat was allowed to be imported on payment of a duty of £1, 4*s*. 8*d*. when the average price over England was 62*s*. a quarter. For every shilling less of price, a shilling was added to the duty; and for a rise of price the duty decreased. In 1842, while the agitation regarding the corn-laws was going on, Sir Robert Peel introduced and carried a modification of the Sliding Scale, which, however, did not succeed in mitigating the popular hostility to the corn-laws. By the Sliding-scale Act of 1842, the duty per quarter was fixed at £1 when the price of corn was under 51*s*., and diminished as the price increased, till on the quarter of wheat attaining the price of 73*s*. it fell to 1*s*. See CORN LAWS.

SLI'GO, a maritime county of the province of Connaught, Ireland, bounded on the N. by the Atlantic and the Bay of Donegal, S. by Roscommon and Mayo, E. by Roscommon and Leitrim, and W. by Mayo. It is 41 m. from E. to W., and 38 from N. to S.; the total area is 461,796 acres, of which about 320,000 are under tillage or in pasture, and 140,000 uncultivated. The pop. in 1861 was 124,845; in 1881, 110,955, of whom 101,148 were Roman Catholics, 8006 Protestant Episcopalians, and the rest of other denominations. The coast-line is indented with numerous bays, and, except in the Bay of Sligo, dangerous for navigation. The surface rises gradually from the coast eastwards as far as an elevated range called Slieve Gamph and the Ox Mountains, the highest point of which rises to 1800 feet. S. contains comparatively few and unimportant lakes, but some of these, however, are extremely picturesque, especially Lough Arrow and Lough Gill Only three of its streams are navigable—the Moy, the Owenmore

and the Garrogue, and they are all inconsiderable. The county is traversed by a railway, which is a branch of the Midland Great Western, and connects the county town of Sligo (q. v.) with Dublin. The mineral products of the county, although not very rich, are various, and consist of copper, lead, iron, and manganese. The climate is variable, and although rain is frequent, it is, on the whole, mild and healthy. The soil in the north is mossy and sandy, both being occasionally intermixed, and at times alternating with a gravelly loam. The plain of S. is a deep rich loam; and in the southern portion of the county are found large tracts of corn-land and pasturage. The occupations of the people are mainly agricultural, and, until some years back, they were chiefly engaged in tillage; but the land is now chiefly used for pasturage. The number of acres under crops of all kinds in the year 1880 was 86,914. The cattle in that year numbered 86,087; sheep, 60,409; and pigs, 12,106. The number of holdings ten years before 1852 had been 13,992; which is now somewhat reduced.

The extent of coast-line has led a considerable number of the population to engage, at least partially and occasionally, in fishing. The S. fishery district comprises 110 miles of coast, and kept engaged, in 1879, 140 registered vessels, employing 572 men and 6 boys. The principal towns are Sligo (q. v.), Ardnaree, and Tobercurry. The number of primary schools in the county in 1871 was 206; superior schools, 12. In 1880 there was, at the National Schools, an attendance of 24,267 pupils, of whom 22,691 were Catholics.

S. was anciently the seat of the O'Connors, and was the scene of many conflicts between the several branches of that family. The domestic feuds of the O'Connors were among the causes which facilitated the first inroads of the Anglo-Normans. The district contains many remains both of the Celtic and of the Anglo-Norman period. Of the former, there is one very interesting called the Giant's Cairn, near Sligo; and there are many raths, cromlechs, and ancient caverns. The county of S. sends two members to the imperial parliament.

SLIGO, chief town of the county of the same name, situated on the river Garrogue; distant from Dublin, with which it is connected by a branch from the Midland Great Western Railway, 131 miles north-west. Pop. (1861) 13,361; (1871) 10,670; (1881) 10,764. Four-fifths of the inhabitants are Roman Catholics. S. had its origin in the erection of a Dominican abbey in the 13th c. by Maurice Fitzgerald, Earl of Kildare, around which—and a castle also built by him—a town was gradually formed. In the reign of James I., it received a charter. The modern town stands within a bend of the river, chiefly on the left bank. It is for the most part well built, and contains several handsome public edifices. It possesses few important manufactures, but is a place of considerable commerce, which is directed with judgment and energy by a body of town and harbor commissioners. In 1880, 758 vessels, of 105,571 tons, entered, and cleared the port. The exports are chiefly of corn, flour, meal, butter, provisions, and yarn. Steamers ply regularly between S. and Glasgow, Liverpool, and Londonderry. S. formerly returned a member to parliament, but was disfranchised in 1870.

SLING, a weapon much in use before the introduction of firearms, consisted of a piece of leather, with a round hole in the middle, and two cords of about a yard in length. A round pebble being hung in the leather by the cords, the latter were held firmly in the right hand, and swung rapidly round. When the stone had attained great speed, one string was disengaged, on which the stone flew off at a tangent, its initial velocity being the same as it had at the last moment of revolution. This velocity gives far greater range and force than could be imparted in mere throwing.

SLIP, in a Dockyard, is a smooth, inclined plane, sloping down to the water, on which a ship is built. It requires to have a very solid foundation. Among modern inventions is a slip on which a sort of truck runs on numerous rails. This truck is run under a ship as she floats; the water is diminished till she rests on it, and it is then hauled up the slip by steam power until she is high and dry. Such a slip takes the place of a dry dock. See also LAUNCH and SHIP-BUILDING.

SLIPPED, in Heraldry, a term of blazon applied to a leaf, branch, or flower, which is represented with a stalk, and torn from the parent stem.

SLOANE, SIR HANS, an eminent physician and naturalist, of Scotch parentage, his father having been the chief of the Scottish colony which was settled in Ulster by James I. of Great Britain, was born at Killyleagh, in County Down, Ireland, 16th April, 1660. He devoted himself during his boyhood to natural history and medicine, and in spite of an attack of hæmoptysis, which lasted from his 16th till his 19th year, he arrived in London in 1679, with an excellent knowledge of the first of these sciences, and a fair acquaintance with the second. His apprenticeship to Stafforth, a pupil of Stahl (q. v.), and the acquaintance, subsequently ripened into close friendship, which he formed with Boyle and Ray, two of the most celebrated naturalists of their time, did much to encourage and advance him in his favorite studies.

During a brief sojourn in France, he attended the lectures of Tournefort and Du Verney, obtained on his return, by the active support of Sydenham (q. v.), a footing in London as a physician, and was elected a member of the Royal Society in 1685, and of the Royal College of Physicians in 1687; but in September of the latter year, he accompanied Monk, Duke of Albemarle, to Jamaica, and investigated the botany of that and the adjoining islands with such zeal and diligence during the 15 months of his stay, that his herbarium numbered 800 species. Resuming his professional practice on his return, he became physician to Christ's Hospital (1694—1724), President of the College of Physicians (1719—1735), Secretary to the Royal Society (1693), Foreign Associate of the French Academy of Sciences (1708), and succeeded Sir Isaac Newton as President of the Royal Society in 1727. He had been created a baronet and physician-general to the army in 1716, and in 1727 received the further honor of being appointed royal physician. Though of remarkably delicate constitution, he lived to the great age of 92, dying at Chelsea, 11th January 1753. The chief point to be remarked in S.'s moral character was his benevolence, as shown in the charitable uses to which he applied the whole of his salary as physician of Christ's Hospital, in his zealous promotion of the various schemes for affording medicine and attendance gratuitously to the poor, and his support of the Foundling Hospital, of which he was one of the founders. By long-continued perseverance, he succeeded in forming a most extensive museum of natural history, a library of 50,000 volumes, and 3560 MSS., which he directed to be offered at his death to the nation for £20,000 (about one-fourth of its real value), and which formed the commencement of the British Museum (q. v.). He also contributed numerous memoirs to the *Philosophical Transactions*, whose publication he superintended for a number of years. But his great work was the *Natural History of Jamaica* (fol. 1707—1725), containing also an excellent account of the topography, meteorology, and population of the island, which book was the means of introducing into the Pharmacopœia a number of excellent drugs, hitherto unknown.

SLOBDO'SK, or SLOBODSKOI', a town of Russia, in the government of Viatka, is situated on the river Viatka, about 16 miles north-east of the town of the same name. Pop. (1867) 6904.

SLOE, or SLOE-THORN (*Prunus spinosa*), a shrub of the same genus with the plum, and perhaps really of the same species with it and the bullace. It is generally a shrub of 4—10 feet high, sometimes becoming a small tree of 15—20 feet. It is much branched, and the branches terminate in spines. The youngest shoots are covered with a fine down. The flowers are small, snow-white, and generally appear before the leaves. The fruit is ovate, or almost globose, pale blue with blackish bloom, and generally about the size of the largest peas. The S. is abundant in thickets and borders of woods, and in arid places in Britain and almost all parts of Europe. The shoots make beautiful walking-sticks. Although spiny, the S. is not suitable for hedges, as its roots spread, and it encroaches on the fields. The bark is bitter, astringent, and tonic. The flowers, with the calyx, are purgative, and are in some places much used as a domestic medicine. The leaves are used for adulterating tea. The unripe fruit dyes black. The fruit is very austere. It is much used on the continent of Europe for making a preserve, also in some places for making a kind of brandy. An astringent extract, called *German Acacia*, is prepared from it, which was once much employed in cases of diarrhœa and mucous and bloody discharges. The juice is much used to impart roughness to port wine, and in the fabrication of spurious port.

SLO'NIM, a town of European Russia, in the government of Grodno, and 72 miles south-east of the town of that name. It has large manufactures of cloth. Pop. (1880) 13,500.

SLOOP is a one-masted cutter-rigged vessel, differing from a cutter, according to old authorities, in having a fixed bowsprit and somewhat smaller sails in proportion to the hull. The term 'sloop' and 'cutter' appear, however, to be used nearly indiscriminately. In the British navy, a sloop-of-war is a vessel, of whatever rig, between a corvette and a gun-boat, and ordinarily constituting the command of a commander. In the days of the sailing navy, sloops-of-war carried from 10 to 18 guns; but, with the introduction of steam, the number of guns has ceased to be distinctive.

SLOPS, in the Navy, are somewhat more extensive than 'necessaries' in the army. They comprise the clothes and bedding of a sailor. Within certain limits, government, acting through the ship's paymaster, supplies the men with slops at cost price. When a sailor dies, his slops are sold by auction for the benefit of his representatives.

SLOTH (*Bradypus*), a genus of mammalia, of the order *Edentata*, and family *Tardigrada*. The name was given from observation of the very slow and awkward movements of the animals of this genus on the ground; but a better acquaintance with their

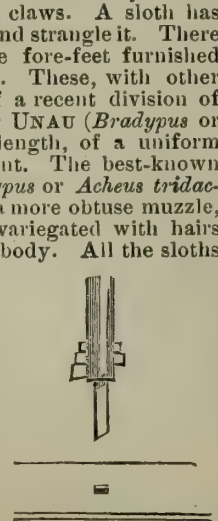
habits, and observation of their movements among the branches of trees, for which their conformation peculiarly adapts them, have shown it to be by no means appropriate or descriptive. In like manner, Buffon's notion that they are creatures of imperfect organization, and doomed to a miserable existence, has been completely exploded. Their structure, like that of every other creature, is admirably adapted to their mode of life. They feed on the leaves, buds, and young shoots of trees, amongst the branches of which they are born and spend their whole life, rarely and unwillingly descending to the ground. They do not walk upon the branches, but cling beneath them, with the back downwards.

The fore-legs are much longer than the hinder ones, and are used for embracing a branch, or for drawing in the branches on the foliage of which they are to feed, and both the fore and hind feet are furnished with very long, curved, and sharp claws. The pelvis is very wide; and the hind-legs, thus widely separated, also diverge from one another. The structure of the wrist and ankle-joints is such that the palm or sole is turned towards the body, so that upon the ground, the animal is compelled to rest on the side of the hind-foot, whilst the length of the fore-legs causes it to rest on the knee or elbow of them, struggling forward by a shuffling movement, and dragging itself along by stretching out the fore-legs alternately and hooking the claws into the ground, or grasping some object. But in a dense tropical forest, sloths generally find it easy to pass from the branches of one tree to those of another, often taking advantage for this purpose of a time when branches are brought within their reach by the wind. Where the trees are more distant from each other, they will eat up the whole foliage of a tree ere they descend from it. The hair of sloths is coarse and shaggy, of a very peculiar texture, inelastic, and much like grass withered in the sun, but affords an excellent protection from insects, whilst it also gives them such an appearance that they are not readily observed except when in motion.

Three-toed Sloth (*Bradypus trydactylus*).

The muzzle of sloths is short, and the tail is short. There are no incisor teeth, but sharp canine teeth, and eight molars in the upper, six in the lower jaw. The molars are cylindrical, penetrated by no laminæ of enamel, and adapted merely for crushing, not for grinding the food. For this, however, there is compensation in the stomach, which is somewhat imperfectly divided, by transverse ligatures, into four compartments, for the longer retention and more thorough digestion of the food, although there is no rumination. The female sloth produces only one young one at a birth, which clings to its mother till it becomes able to provide for itself. The voice of sloths is a low plaintive cry. Their chief enemies are large snakes, but against these they defend themselves by their powerful fore-legs and claws. A sloth has been known to grasp a dog round the neck and strangle it. There are very few species. One species has the fore-feet furnished with only two toes; the others have three. These, with other differences, have been made the ground of a recent division of the genus into two. The TWO-TOED S., or UNAU (*Bradypus* or *Cholœpus didactylus*), is about two feet in length, of a uniform grayish-brown color, often with a reddish tint. The best-known species of THREE-TOED S. is the AI (*Bradypus* or *Acheus tridactylus*), which is smaller than the Unau, has a more obtuse muzzle, and is generally brownish gray, slightly variegated with hairs of different tints, the head darker than the body. All the sloths belong to the tropical parts of America.

SLO'TTING-MACHINE, a machine for cutting slots, or square grooves, in metal. It is of great importance in mechanical engineering, and many very ingenious inventions have been made for facilitating the process. The principle is, however, very simple, and is the same in all. It consists of a cutting tool, or chisel, held very firmly in an arm, which is pressed down and raised alternately. The tool is thus made to pare off a thin portion of the metal each time it descends, until it has cut a slot of sufficient size. Water is continually thrown on, to prevent the metal from becoming overheated by the friction.



Slotting-machine.

SLOUGH, a village of England, in the county of Buckingham, 18 miles west of London, by the Great Western Railway. On the road between S. and Windsor, which is distant about two and a half miles, lived Sir William Herschel, and at the observatory which he erected here, in which was placed his great telescope, many of his important astronomical discoveries were made. Pop. (1871) 4509; (1881) 5080.

SLOVAKS, THE, are the Slavic inhabitants of North Hungary, who, in the 9th c., formed the nucleus of the great Moravian kingdom, but who, after the bloody battle of Presburg (907 A.D.), were gradually subjugated by the Magyars, to whom even yet they bear no friendly feeling. The S., who are of a soft, pliant disposition and industrious character number about 1,900,000, and are mostly Catholics. The S., whose character probably comes nearest to that of the old Slavic type, travel in great numbers over Germany and Poland as Pedlars. Their language is a dialect of Bohemian. Among the most notable of the Slovak authors are the poets Holly and Kollar (q. v.); Matth. Bel (1684—1749); Stephan Leschka (1757—1818) editor of the first Slovak journal; Bernolak, author of a Slovak grammar; Palkovitsh (died 1835); and Tablitsh, who published four volumes of poetry (1806—1812). A fine collection of popular Slovak ballads has been published by Kollar (2 vols., Ofen, 1834).

SLOW-MATCH, a combustible material, such as cotton, hemp, tow, &c., often dipped in a solution of nitrate of potash (saltpetre), and formed into a thin rope. It is used for exploding gunpowder in various ways, on account of its slow, steady way of burning, a sufficient length being taken to enable the operator to remove to a safe distance before the explosion. Slow-match was much used by artillerymen for firing of cannon, but it has generally given way to friction fusees and percussion caps.

SLUBBING. See SPINNING.

SLUG (*Limax*), a genus of gasteropodous molluscs, of the division *Monœcia* (hermaphrodite), and of the family *Limacidæ*, which is closely allied to the snail family, *Helicidæ*, but has no external shell. There is, however, a rudimental shell, generally concealed within the mantle, placed over the respiratory cavity. The *Limacidæ* are diffused over the whole world. They commit great ravages among field and garden crops during moist weather. In frosts, they become dormant, taking shelter under clods and at the roots of plants. They lay eggs in clusters, in moist places, often at the roots of grass. The eggs resemble small oval bags of jelly. The body is generally oval or oblong, elongated. The foot is not distinct from the body. There are four retractile tentacles; the eyes are at the tips of the longer pair. Slugs often climb trees in quest of decaying vegetable matter on which to feed, and let themselves down by means of mucous threads, for the formation of which there is a small aperture at the hinder end

Slugs.
1. Gray slug; 2. Black slug; 3. The same full grown, and as it appears when at rest; 4, Its eggs.

of the body. Of British species, one of the most common is the GRAY S. (*Limax agrestis*), which is of a whitish ash color; another is the GREAT GRAY S. (*L. maximus* or *antiquorum*), the largest British species; another is the BLACK S. (*L. ater*), often popularly called the Black Snail. The RED S. (*Agrion agrestis*) is also very plentiful. Careful gardeners often gather slugs by the aid of a lantern at night, and destroy them. The may also be killed by watering the ground with a weak solution of ammonia.

SLUR, in Music, an arch drawn over two or more notes *not* on the same degree, to indicate that these notes are to be played *legato*, or smoothly and fluently  . In vocal music a slur is placed over all the notes that are to be sung to the same syllable, unless where they are grouped together by a common line. A slur must be distinguished from a *tie*, which is a similar arch drawn over two notes on the same degree, and denoting that

instead of the two notes written, one is to be played of the length of both.

SLUTSK, a town of European Russia, in the government of Minsk, about 63 miles S. of the town of that name, near the source of the Lesser Slutch. With the exception of its public buildings, the houses are almost entirely of wood. Pop (1880) 17,200.

SMACK is a generic term for small decked or half-decked vessels employed in the coasting and fishing trade. The majority of smacks are, however, rigged as cutters, sloops, or yawls. According to Wedgewood, the *m* in this word is a corruption of *n*; the Anglo-Saxon has *snakk*, a small vessel, and there is a corresponding form in the other Teutonic and Scandinavian tongues.

SMALL-ARMS, in the modern acceptation, consist of the weapons actually carried by a man. They have been described under their respective heads, BAYONET, FIREARMS, LANCE, SWORD, PISTOL, &c.

SMALL-ARMS FACTORIES, ROYAL, are the establishments through which all the small-arms of every description are supplied to the regular army, the militia, yeomanry, and volunteers. The headquarters are at Enfield, where there is a vast manufactory; and at Birmingham, there is a considerable establishment for viewing the arms supplied by contractors. For many years, there had been a small ordnance factory at Enfield Lock, where a few thousand muskets were laboriously forged by hand each year; but when the sudden introduction of the rifle, and the demands of the Russian war, called for a supply of arms, which the trade of all Europe and America was unable to meet, government determined to erect machinery for the fabrication of arms. For this purpose, the factory at Enfield was entirely remodelled; machinery of great power and delicacy was adopted, and now, when in full work, the factory can turn out daily 1000 complete and proved rifles, besides a corresponding complement of other small-arms. At the same time, the accuracy of workmanship is so great, that a hundred rifles might be taken entirely to pieces, the several portions thrown promiscuously together, and a hundred complete rifles could be forthwith re-formed without any difficulty from the same pieces. Much of the merit of this great establishment was due to Major-general Manley Dixon of the Royal Artillery, who long superintended the factory after it was remodelled. The success of the factory has reduced in a remarkable degree the cost of rifles, and has brought down correspondingly the price charged by the trade for the large quantities still intrusted to it. The successive adoption of the Snider and Martini rifles has been the means of producing a great change in the plant at Enfield.

The cost of the factories, when in full operation, is of course considerable. In the year 1874, when the army was being armed with the Martini rifle, the charge was £172,837; in 1883, £115,234.

SMALL DEBTS is a phrase current in Scotland to denote debts under £12, recoverable in the Sheriff Court. See SHERIFF. In England, the same debts are recoverable in the County Court (q. v.).

SMALLPOX, or VARI'OLA, is one of the most formidable of the class of febrile diseases known as the *Exanthemata* (q. v.). All cases of regular smallpox are divisible into three stages—viz. (1), that of the initial or eruptive fever; (2), that of the progress and maturation of the specific eruption; and (3) that of the decline. Some writers make a primary stage of the period of incubation or of the time intervening between the reception of the poison into the system, and the first appearance of febrile symptoms; but this is not entitled to be regarded as a stage of the disease, seeing that no symptoms of disorder have begun to show themselves. The *first stage* begins with rigors, followed by heat and dryness of the skin, a quickened pulse, furred tongue, loss of appetite, pain in the pit of the stomach, with nausea, vomiting, headache, and often pains in the back and limbs. The violence of the pains in the back, and the obstinacy of the vomiting, are frequently very well marked and characteristic symptoms. In children, the disease is often ushered in by convulsions; while delirium sometimes attends its outset in adults. On the third day, minute red specks begin to come out first on the face, then on the neck and wrists, and on the trunk of the body, and lastly on the lower extremities. The fever usually begins to subside as soon as the eruption appears, and by the beginning of the fifth day, when the eruption is generally completed, the fever has entirely disappeared. The *second stage* commences when the eruption is fully out.

Upon the second or third day of the eruption, a little clear lymph is seen in each pimple, which has increased considerably in size since its first appearance, and which is thus converted into a *vesicle*. The vesicles gradually increase in breadth, and become converted into *pustules*, which are at first depressed in the center, but by the fifth day of the eruption become turgid and hemispherical; the suppuration on the face being complete by about the eighth day from the commencement of the fever, and the same process rapidly following in the other parts of the body in the same order of succession as that in which the eruption originally appeared. The pustules then break, and scabs or crusts form over them, which usually fall off after four or five days' existence. The number of pustules in any special case and the severity of the disease, stand in a direct ratio to one another; for 'the number of pustules indicates, in the first place, the quantity of variolous poison which has been reproduced in the blood; and, in the second place, it is also a direct measure of the extent to which the skin suffers inflammation. Sometimes there are not more than half-a-dozen pustules; sometimes there are many thousands. If all these were collected into one, it would be an enormous phlegmon. For both these reasons, the system suffers commotion, distress, and peril, in proportion to the quantity of the eruption.'—Watson's *Lectures*, &c., 4th ed. vol. ii. p. 857. The progress of the pustules is usually accompanied with swelling of the skin of the face, with a painful sensation of heat and tension; the scalp is often swollen; soreness of the mouth and salivation usually supervene; and the patient exhales a peculiar and disagreeable odor.

About the eighth or ninth day of the disease, a recurrence of the fever, known as 'the fever of maturation,' sets in with varying degrees of intensity, according to the number and arrangement of the pustules. When the pustules are numerous, they run together; when they are few, they keep separate. Hence the division of smallpox into the two great varieties of *distinct* and *confluent*, or *variola discreta* and *variola confluens;* and this division is of the highest importance, because the distinct form of the disease, in which the pustules are isolated, is scarcely ever dangerous; while the confluent form in which they coalesce, is never free from danger. The *third* or *declining stage* is, in the distinct variety, little more than a period of convalescence. About the eleventh or twelfth day, the pustules on the face become brown and dry at the top, or some of them break, and the fluid which oozes out solidifies into a yellowing crust; and from this time the process of *desiccation* goes on, the swelling of the face subsides, and at last only dry scabs remain, which gradually fall off about the fourteenth day. It is not till three or four days after the scabs have formed on the face, that the same process is completed over the whole body. The scabs are usually completely gone by the twenty-first day, leaving behind them blotches of a reddish brown color, which sometimes continue for some months before they quite disappear; and some of the pustules, in consequence of ulceration of the true skin, leave pits, especially on the face, which remain permanently.

The period of scabbing is accompanied by various symptoms of improvement: the tongue becomes clean, the appetite returns, and by the time that the scabs have fallen off, the patient may be regarded as restored to health; so that the entire course of a case of distinct or discrete smallpox occupies about three weeks. In the confluent form of the disease, the eruptive fever is more violent, the pain in the back is more severe, and the sickness more obstinate, and the eruption comes out earlier and less regularly than in the distinct variety which we selected for description as representing the more natural course of the disease. Moreover, the pustules do not fill so completely, nor are they of the normal yellow purulent hue, being whitish, brown, or even purple. But the most important difference between the two forms is in the *secondary fever*, which sets in when the pustules are mature. This fever, which is slightly marked in distinct smallpox, is usually intense, and highly dangerous in the confluent form; and it is at this period of the disease that death most commonly occurs. Statistics show that the eighth day of the eruption is the most perilous *day*, and the second week the most perilous *week*. The early occurrence of death—that is to say, during the first week—denotes a peculiar malignancy in the disease. 'The nervous system,' says Dr. Watson, 'appears to be overwhelmed by the force of the poison. During the second week, the disorder proves fatal chiefly in the way of apnœa; from some affection of the respiratory passages. After that period, the characters of asthenia commonly predominate, the patient sinks under some casual complication, or the powers of life are gradually worn out by so much irritation of the surface, and so large an amount of suppuration.' —*Op. cit.*, vol. ii. p. 860.

The above are the essential symptoms of smallpox, both in the distinct and confluent form. This disease is, however, often accompanied by other symptoms, which we have merely space to name; such as sore throat (which often depends upon pustules situated there), salivation, and (in the confluent form, during the secondary fever) erysipelatous inflammation, leading to the formation of abscesses, glandular swellings, sloughing sores on the sacrum, &c. In pregnant women, the disease often causes abortion, which is most commonly followed by death. The dead child occasionally, but not often, is covered with pustules.

The *cause* of smallpox is universally allowed to be a specific contagion, of whose nature we are in the most profound ignorance. There is probably no disease so contagious as this. Dr. Haygarth stated (in 1793) that, during his long attention to this

subject, not a single instance has occurred to prove that persons liable to smallpox could associate in the same chamber with a patient in the distemper without receiving the infection; and he was informed by an American physician of an instance in which the poisonous effluvium crossed a river 1500 feet wide, and affected ten out of twelve carpenters who were working on the other side. The contagion acts either through the air, or by contact with the skin, or by inoculation; and the disease may be caused by the dead body, even when it has not been touched. What products of the diseased body are contagious, is not exactly known, but the contents of the pustules and the dried scabs certainly are so. Opinions are divided as to the period at which the disease begins and ceases to be contagious. It is safest to maintain that it is capable of self-propagation as soon as the febrile symptoms have exhibited themselves. How soon the patient ceases to be dangerous, cannot be decided with accuracy; but the stability of the contagious principle may be inferred from the fact, that clothing will retain it for months, and it is said for years, when confined.

Like all the contagious exanthemata, smallpox appears in an epidemic form, at irregular, and, in our ignorance, it would almost seem capricious intervals. After an extraordinary exemption, perhaps for years, a district is suddenly invaded by it, and continues to suffer for a longer or shorter period, after which the disease spontaneously disappears—dies out, as it were—and does not reappear perhaps for years. Different epidemics vary very much in their severity, and isolated cases are usually milder than those occurring when the disease is epidemic. Race has much to do with the severity of the disease; the constitution of the dark races, the Negro and the Red Indian, being singularly susceptible of the contagion, and exhibiting very little power of resisting the fatal tendency of the disease.

It is universally admitted that the discovery of *Vaccination* (q. v.), by which smallpox is deprived of its danger, is the greatest triumph of modern medicine. *Inoculation* (q. v.) protected the individual, but increased rather than diminished the total number of deaths, while vaccination has the advantage of protecting both the individual and the community. Although, in the great majority of cases, vaccination affords perfect protection against smallpox, it not very unfrequently happens that vaccinated persons, when exposed to the contagion of smallpox, get the disease in a modified form, milder and shorter even than after inoculation, and therefore incomparably milder than in the natural form. The disorder occurring under these circumstances, has received the various names of *modified* or *post-vaccinal* smallpox, or the *varioloid* disease. As Dr. Wood observes: 'It is impossible to describe minutely all the shapes which the varioloid disease assumes. There is every shade between the slightest symptoms, scarcely recognizable as having affinity with smallpox, and the nearest possible approach to the regular disease.'—*Practice of Medicine*, 4th ed., vol i. p. 380. In whatever form the varioloid disease appears, it wants the peculiar odor of smallpox, and secondary fever is very rare. The constitutional disturbance which, for the first week, may have been as severe as in the true disease, usually subsides entirely when the eruption has reached its height, and the patient is convalescent at the period when, if he had not been vaccinated, he would have been in the greatest danger.

With regard to prognosis, it may be stated generally, it is a very fatal, and was formerly an extremely destructive disease—one death occurring in every four cases. Modified smallpox is very seldom fatal, although instances of death are occasionally reported. Smallpox is more fatal at the two extremes of life than in the intervening period, and, as has been already noticed, is especially dangerous in pregnancy. In olden times, it was believed that the eruption was an effort of nature to get rid of the noxious matter, and hence heating and stimulating measures were adopted with the view of promoting the eruption. To Sydenham (q. v.) belongs the credit of first recommending an entirely opposite or cooling mode of treatment; but his suggestions met with the most severe opposition, and it was not till long after his death that the cooling treatment was fairly established. In mild cases, and in cases of varioloid disease, the physician has merely to guard the patient against hurtful influences, such as stimulating foods or drinks, too hot a room, or improper exposure to cold, and to prescribe cooling drinks during the fever, and occasional laxatives if they shall be required. In more severe cases, the fever may be combated by saline purgatives, prescribed so as to produce two or three liquid stools daily, and by free ventilation of the surface of the body. When the eruption is all out, if the pimples on the face are few and distinct, the danger may be regarded as over, and no further treatment is required. If, however, the disease assume a confluent form, wakefulness and restlessness are apt to come on about the eighth day, and opiates in free doses may be prescribed with benefit.

If the pustules are abnormally torpid in reaching their maturity, it may be expedient to administer strong broths, or even wine; and when the pustules are livid, and intermixed with Petechiæ (q. v.), bark and acids must be additionally ordered, although the patient is then too often beyond the reach of help. During the secondary fever, the bowels must be kept gently open, and opiates should be prescribed once or twice each day. A more nourishing diet is now called for, and wine should be given if the pulse is very weak. The external itching is partly relieved by the opiates, but local applications are also employed: cold cream, or a mixture of equal parts of olive oil and lime-water, may be thus used with advantage. Special methods have been devised for the purpose of preventing the pitting or seaming of the face, which is often a hideous permanent disfigurement to the patient. The best application of this kind is probably that of nitrate of silver. Mr. Higginbottom, who first suggested this application, touched each distinct papula with a solid stick of lunar caustic, previously moistened; but when the spots were confluent, he washed the whole face, about the third day after the eruption, with a strong solution of this salt, containing eight scruples to the ounce of water. In the Paris hospitals, various mercurial preparations are employed, which are said to cause the pustules to abort. M. Briquet recommends mercurial ointment simply thickened with powdered starch. Dr. Wood of Philadelphia remarks, that as the ointment sometimes salivates, it should be diluted with an equal quantity of lard before the starch is added. Professor Bennett of Edinburgh recommends the application of calamine (carbonate of zinc) mixed with olive oil; it forms a coherent crust, and thus excludes the air.

During the period of desquamation, an occasional warm bath may be prescribed with advantage; and the patient should always resort to this measure, as a precaution against carrying the contagion about with him, before again mixing in society.

The history of this remarkable disease is clothed in considerable obscurity. There is no evidence that it was known to the Greek or Arabian writers of the 6th c., and the first accurate description of it is that of Rhazes, an Arabian physician, who flourished early in the 10th century. It appears to have reached England towards the close of the 9th century. After the Crusades, it prevailed in most of the temperate countries of Europe, but did not reach the northern countries of Norway, Lapland, &c. for some time later. In 1517, it was carried from Europe to St. Domingo; and three years later, it reached Mexico, where it committed fearful devastations, and whence it spread with intense virulence throughout the New World. (According to Robertson, three millions and a half of people were destroyed in Mexico alone.) In 1707, it was introduced into Iceland, when more than a fourth part of the whole population fell victims to it; and it reached Greenland still later (in 1733), when it spread so fatally as almost to depopulate the country. These cases are striking illustrations of the law that seems universally true, that a contagious disease is always most virulent on its first introduction to a new scene of action.

SMALLPOX IN SHEEP (*Variola ovina*), although resembling the smallpox of men, is a distinct disease, not communicable either by contagion or inoculation to men or children, or even to dogs or goats. Although common on the continent of Europe, it was unknown in this country for at least a century, until in 1847 it appeared in Norfolk and the eastern counties, and in the summer of 1862 in Wiltshire, near Devizes. Variolous sheep or infected skins appear in both cases to have imported the disease from abroad. About ten days after exposure to contagion, the infected sheep become feverish, have a muco-purulent nasal discharge, and a hot tender skin. The red pimples which first appear, in about three days become white, and afterwards leave scabs or ulcers. The weakness is great, and the mortality varies from 25 to 90 per cent. Good food and nursing are the appropriate remedies. Promptly and carefully must the sick be separated from the sound; but if the spread of the disorder be not thus immediately checked, the whole of the sound flock should be inoculated. The disease thus artificially produced appears in ten days, runs a mild course, occasions a loss of from two to five per cent., and in three weeks the disorder is got rid of, and all risk of contagion over.—Further details will be found in Professor Simmonds' 'Report on Smallpox,' in vol. 25 of the *Journal of the Royal Agricultural Society of England*.

SMALT, a name applied to the colored glass compositions used for making the tesseræ employed in forming mosaics. See also COBALT.

SMART-MONEY. See RECRUITING.

SMEATON, JOHN, an eminent civil engineer, was born at Austhorpe, near Leeds, in 1724, and early showed a bent towards mechanical pursuits. At the age of 15, he had constructed a machine for rose-engine turning. About 1750, he removed to London, to commence business as a mathematical instrument maker; but we find him in the following year resuming his desultory experiments in mechanical invention, an 'odometer' for ships, a compass, and improvements in water and wind mill-machinery being the chief products of his inventive genius. His improvements on mill-work were found on trial to be of great

value, increasing the effective force by one-third, and gained S. the Copley Medal of the Royal Society in 1759. In 1753, he was chosen a member of the Royal Society; and in the following year, to extend his practical acquaintance with engineering, he visited the Netherlands, and inspected the embankments, canals, and other remarkable works of that country. In 1755, an event occurred which was to afford him the opportunity of attaining the very summit of his profession—the second wooden light-house on Eddystone rock was destroyed by fire in December. The speedy re-erection of another beacon was of the utmost importance, and the execution of the work was intrusted to Smeaton. The new light-house was built of stone; the cutting of the rock for the foundations commenced in August 1756, the building was executed between June 1757 and October 1759, and the lantern lighted on 16th October of the latter year. This great work, the greatest of its kind hitherto undertaken, remained for 120 years a stable monument of S.'s engineering skill. Yet he seems to have had little employment for some time subsequently, as he applied for and obtained in 1764 the post of 'receiver of the Derwentwater estate,' the funds of which were applied for the behoof of Greenwich Hospital; and this situation he held till 1777, by which time he was in full professional employment.

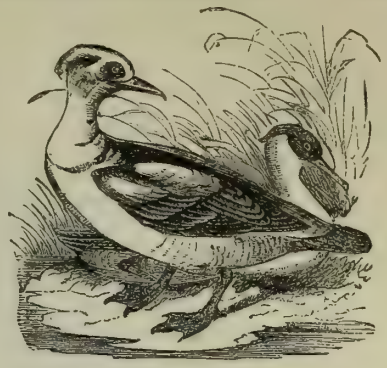
The chief of his other engineering works were, the construction of the greater portion of Ramsgate harbor (1774); the laying out of the line of the Forth and Clyde Canal, and the superintendence of the excavation of most of it; the rendering of the Calder (Yorkshire) navigable; the erection of Spurn light-house, and of several important bridges in Scotland, together with an immense amount of mill-machinery. He also greatly improved Newcomen's steam-engine, but the mighty achievements of Watt in the same field threw his labors completely into the shade. He is said to have prevented the fall of the old London Bridge for many years by sinking a great quantity of stones around one of the piers, which had become undermined by the strength of the Thames current. In 1783, his health began to decline, and he retired from active business, dying at Austhorpe of paralysis, 28th October 1792. He was one of the chief promoters of the 'Society of Civil Engineers,' which was started in 1771, and after S.'s death published (1797) in three 4to volumes his numerous professional Reports, which were regarded by his successors 'as a mine of wealth for the sound principles which they unfold, and the able practice they exemplify.' For a large portion of his life S. was in constant attendance on parliament, which, in difficult or important engineering schemes, invariably demanded, and almost always followed, his advice—a proof not only of his eminence in his profession, but of his caution, judgment and integrity. See the biography prefixed to his 'Reports.'

SMELL. See NOSE.

SMELT (*Osmerus*), a genus of the Salmon or Trout family (*Salmonidæ*), of which only a few species are known, differing from the salmon, trout, &c. in having long conical teeth on the jaws and tongue, and on the tip of the vomer, the rest of the vomer being destitute of teeth; two distinct rows of teeth on each palatine bone.—The COMMON S. (*O. eperlanus*), called *Spirling* or *Sparling* in Scotland, and *Eperlan* in France, is a fish of 8 or 10 inches (rarely 12 inches) in length. The form is very trout-like—rather more slender—the tail larger in proportion, and more forked. The lower jaw is much longer than the upper. The scales are small; the back is whitish, tinged with green; the upper part of the sides shows bluish tints, the lower part of the sides and the belly are of a bright silvery color. The S. has a peculiar, cucumber-like smell, and a delicious flavor, on account of which it is highly esteemed for the table, where it often appears as an accompaniment of other fish. The S. is partly an inhabitant of fresh water, and partly of the sea. It ascends rivers to no great distance from the sea in autumn, and descends in spring. Great numbers of smelts are taken in estuaries, and near the mouths of rivers by small-meshed nets. They are also taken on the open sea-coast, chiefly on low sandy shores, as that of Lincolnshire. The attempt has been successfully made to keep the S. continually in fresh-water ponds, in which it not only throve well, without loss of flavor, but propagated abundantly. No effort has yet been made to turn this discovery—not a very recent one—to any economical account. Although found both on the eastern and western coasts of Britain, the S. is unknown on the south coast of England, where the name S. or SAND S. is given to the Atherine (q. v.).—Another British species, the Hebridean (*O. Hebridicus*), was first discovered near Rothesay in 1837, and described by Yarrell. It is so rare as to be unimportant.—The AMERICAN S. (*O. viridescens*) is regarded as distinct from the Common Smelt. It has a longer body and a greener back. It is found on the north-eastern coasts of America, as far south as the Hudson.

SMELTING. See IRON.

SMEW (*Mergellus albellus*), a bird of the family *Anatidæ*, very nearly allied to the goosander and mergansers, but having a shorter bill. The whole length of the male is not quite 18 inches; that of the female, not quite 15. The S. is only known in Britain as a winter visitant, appearing in greatest numbers in severe winters, and sometimes on inland lakes and ponds, as well as on the sea-



Smew (*Mergellus albellus*).

coast. It abounds on the northern coasts of Asia, and in some parts of continental Europe.

SMILA'CEÆ, a natural order of exogenous plants, ranked by Lindley in his class Dictyogens (q. v.), and consisting of herbaceous or half-shrubby plants, generally more or less climbing, with reticulated leaves, and bisexual or polygamous flowers, a 6-parted perianth, six stamens, a free 3-celled ovary, with cells one or many seeded, three stigmas, and a roundish berry. There are about 120 known species, mostly of the genus *Smilax*, scattered over the globe, but most numerous in the temperate and tropical parts of Asia and America. The root-stocks (*rhizomes*) of many species yield Sarsaparilla (q. v.). But some species have fleshy tubers, particularly *Smilax China*, a native of China and Japan, the tubers of which are very large and nutritious, and used for food. *Smilax pseudo-China*, an American species, has similar tubers.—The roots of *Roxburghia viridiflora*, after being boiled and soaked in lime-water, to remove their acridity, are preserved in syrup as an article of food in the Eastern Peninsula and Malayan Islands. The stems of this plant are sometimes 100 fathoms long.

SMITH, ADAM, the founder of political economy as a separate branch of human knowledge, was born in the town of Kirkcaldy, in Fifeshire, on the 5th of June 1723. His family belonged to the respectable middle class of Scotch life; his father was comptroller of the customs at the port of Kirkcaldy, and his mother, Margaret Douglas, was the daughter of a small Fifeshire laird. His father died a short time before his birth, and he was the object of the care and solicitude of a widowed mother, to whom he was closely attached, and who long lived to be proud of his attainments. When he was no more than three years old, the poor woman got a sad fright from a calamity hardly known at the present day—the child was stolen by gipsies; but he was tracked and recovered by his uncle as they were seeking a hiding-place in the neighboring wood of Leslie. This was the only adventure in his quiet life. After getting the usual burgh-school education in Kirkcaldy, he was sent, in 1737, to the university of Glasgow. He there secured an exhibition on the Snell foundation, which took him to Balliol College, Oxford. He studied there for seven years, and left traditions as of a man of large acquirements and peculiar independence of thought. It is said that he was intended for the English Church, but if so, his own convictions crossed the designs of his friends. He returned to Kirkcaldy, and lived for a while with his mother there in undisturbed seclusion and study. It was said to be his practice to stand ruminating, with his back to the fire, and his head leaning against the chimney-piece—and over an old fire-place in Kirkcaldy it used to be shown how he had thus worn a piece off the paint. In 1748 he came to Edinburgh, where silently and unostentatiously he became one of the brilliant little circle of men of letters who were then rising to importance. In 1751, he got the chair of Logic in the university of Glasgow, and this was changed a year afterwards for that of Moral Philosophy.

In 1759, appeared his *Theory of Moral Sentiments*, celebrated for its reference of the mental emotions to the one source of sympathy. The *Dissertation on the Origin of Languages* was published along with the latter editions of this book. Both had a great reputation in their day, and although they are now among obscure books in comparison with that other by which the author's name is remembered, the position they held with respectable thinkers gave a hearing to his doctrines on political economy which they would hardly have otherwise obtained. In 1762, the university of Glasgow gave him the degree of Doctor of Laws. In the following year he undertook a task, which might at first seem very uncongenial to a mind like his, given to retired study and independent thought and action. He became 'governor' or

traveling tutor to the young Duke of Buccleuch. He was then sedulously collecting materials for his great work, and no doubt the inducement to accept of the office was the opportunity it gave him for traveling and seeing for himself. He had the opportunity of being nearly a year in Paris, and of mixing in the circle of renowned wits and philosophers of the reign of Louis XV. In 1766, his function came to an end, and he returned to Kirkcaldy to live in the old house with his mother. The year 1776 was an era in the history of the world as well as that of the Kirkcaldy recluse, in the appearance of the *Inquiry into the Nature and Causes of the Wealth of Nations*. If there was any living man to whose works he was indebted for the leading principles of this book, it was David Hume, and it was from him, as best understanding the fulness and completeness of the exposition, that it had its first emphatic welcome. He wrote immediately on receiving it: 'EUGE BELLE.—DEAR MR. SMITH—I am much pleased with your performance; and the perusal of it has taken me from a state of great anxiety. It was a work of so much expectation by yourself, by your friends, and by the public, that I trembled for its appearance, but am now much relieved. Not but that the reading of it necessarily requires so much attention, and the public is disposed to give so little, that I shall still doubt, for some time, of its being at first very popular. But it has depth, and solidity, and acuteness, and is so much illustrated by curious facts, that it must at last take the public attention.'

This was not destined to be exactly the literary history of this great work. Its startling doctrines, fine clear style, and abundant illustration from curious facts took at first; but counteracting influences arose when people saw how far the new doctrines went in playing havoc with old prejudices. The French revolution set the mind of this country bigoted against everything that breathed of innovation. It was known that the younger Pitt participated at first in S.'s free-trade notions, but he had afterwards, whether from permanent connection or temporary policy, to put himself in the foremost ranks of the enemies of innovation. It was not until long after the terrors of that epoch and the nervous vicissitudes of the war had passed over, that S.'s work had an opportunity to revolutionize the public mind on matters of trade and finance. It came up, as it were, the leader of a great literary host, for expounders had crowded in numbers round *The Wealth of Nations* as the text-book of sound economy. Of a book so well known and so much read, it is needless to speak. The only reproach brought against it is, that it is not systematic in its form, and that its nomenclature is not exact. But its author was not arranging the results of established knowledge—he was rather pulling down existing structures, compounded of ignorance and prejudice. Nor, indeed, have those who have attempted to make an exact science out of political economy, practically vindicated the reproach they have cast on him of being unmethodical. Whatever we may yet come to, very few portions indeed of political economy admit of being treated as exact science. It is too closely connected with human passions and energies, and consequently with special results and changes, to be so treated; and the best books on the subject are still characterized by the discursiveness and mixed philosophy and fact of the *Wealth of Nations*. In 1778, S. was made a Commissioner of Customs. The only effect of this was to bring him to Edinburgh, and increase his means for indulging in his favorite weakness, the collection of a fine library; for he was, as he called himself, a 'beau in his books.' In 1784, he suffered that affliction which was sure to come if he lived long enough for it—the loss of his worthy mother. He followed her six years afterwards, dying in July 1790.

SMITH, ALEXANDER, poet, was born at Kilmarnock, in Ayrshire, December 31, 1830, received, as a boy, a fair English edution, and passed from school into a Glasgow warehouse as a pattern designer. While following this occupation, he began to write poetry. His first volume, entitled the *Life Drama*, was published in 1853, and created something like a furor in literary circles. A reaction, however, followed, and the author had scarcely found himself famous when he began to be abused. The faults of his book were obvious enough: every page contained evidence of immaturity, and its natural result, extravagance; while a rather narrow reading having made him passionately attached to a few modern poets, as Keats and Tennyson, their peculiar turns of expression reappeared in his verse, and gave color to the charge of plagiarism, which was pushed to an absurd length. But impartial critics were not slow to perceive a richness and originality of imagery that more than atoned for all defects of taste and knowledge. In 1854, S. was appointed Secretary to the university of Edinburgh; and in the following year, along with Sydney Dobell (q. v.), produced a volume of *Sonnets on the War*. He afterwards wrote *City Poems* (1857), *Edwin of Deira* (1861), and several prose works, as *Dreamthorp* (1863), *A Summer in Skye* (1865), and *Alfred Hagart's Household* (1865). S. was perhaps not less distinguished as a writer in prose than in verse, his prose style being marked by picturesqueness, polish, and originality. He died in 1867.

SMITH, GOLDWIN, LL.D., son of a Berkshire physician, was born at Reading in 1823. He received his education at Eton, from whence he proceeded to Oxford, and matriculated at Christ's Church, but was soon afterwards elected to a Demyship at Magdalen. His undergraduate career was one of unusual brilliancy, only equalled, indeed, by Sir Roundell Palmer and Professor Conington. He gained both University Scholarships, the Latin Verse, and the two Prize Essays, and was placed in the first class in 1845. In 1847, he was elected Fellow of University College, where he officiated for a time as tutor. In the same year he was called to the bar at Lincoln's Inn. The ministry of the day availed themselves of Mr. S.'s services in carrying out their plans of university reform. He was nominated Assistant-secretary to the first, and Secretary to the second Oxford Commission, by which the somewhat antiquated statutes of the university were reconstructed, and the rich endowments of the colleges opened to public competition. Mr. S. was also a member of the Popular Education Commission appointed in June, 1858. The chair of Modern History having been vacated about this time by the resignation of Professor Vaughan, was offered by Lord Derby to Mr. S. He accepted the offer, and discharged his professional duties with zeal and efficiency until his resignation in 1866. In 1868, he was elected to the chair of English and Constitutional History in the university at Ithaca, New York. He has lately resided in Canada. Goldwin S. has long been known as a publicist of the highest class, and has completely identified himself with the more advanced school of reformers.

During the American war, he was an earnest defender of Federal interests, and combated with success, in the *Daily News* and elsewhere, the singular theories of the rights of slavery and the duties of neutrals, which were then somewhat fashionable. He was also active in denouncing the Jamaica massacres, and in advocating an extended measure of reform. His lectures on 'Three English Statesmen,' delivered at some of the chief towns in the north, called forth the remark from Mr. Disraeli that he was a 'wild man of the cloister, going about the country maligning men and things.' Mr. S.'s writings are characterized by great extent and accuracy of information, by a style singularly vigorous and condensed, and by great powers of sarcasm. Among his principal publications may be enumerated: *Irish History and Character; Two Lectures on the Study of History, with a Supplementary Lecture on the Doctrine of Historical Progress; The Empire*, a reprint from the *Daily News* of 1862—1863; *England and America*, a lecture delivered before the Boston Fraternity, and reprinted from the *Atlantic Monthly; A Plea for the Abolition of Tests at Oxford; Rational Religion and the Objections of the Bampton Lecture in* 1858; several pamphlets on the American question; contributions to Oxford Essays; *A Short History of England;* &c. He is also the author of some of the most admired compositions in the *Anthologia Oxoniensis*.

SMITH, JAMES AND HORACE, authors of *The Rejected Addresses*, were sons of an eminent London solicitor. James was born February 10, 1775, died December 24, 1839; Horace was born December 31, 1779, died July 12, 1849. James followed his father's profession, and succeeded him as solicitor to the Board of Ordnance; Horace adopted the profession of a stock-broker, and realized a handsome fortune, on which he retired with his family to Brighton. Both were popular and accomplished men—James remarkable for his conversational powers and gaiety, and Horace (the wealthier of the two) distinguished for true liberality and benevolence. The work by which they are best known is a small volume of poetical parodies or imitations, perhaps the best in the language. On the opening of the new Drury Lane Theater in October 1812, the Committee of Management advertised for an address to be spoken on the occasion, and the brothers Smith adopted a suggestion made to them, that they should write a series of supposed 'Rejected Addresses.' They accomplished their task in the course of a few weeks—James furnishing imitations of Wordsworth, Southey, Coleridge, Crabbe, Cobbett, &c.; while Horace contributed imitations of Scott, Byron (all but the first stanza), Monk Lewis, Moore, and others. In point of talent, the authors were about equally matched; for though James had the greater number of successful imitations, the one by Horace of Scott, is the most felicitous of the whole. It is a curious fact in literary history that a work so exceedingly popular should have had great difficulty in finding a publisher; and that the copyright, which had been originally offered to Murray for £20, and refused, was purchased by him in 1819, after the book had run through 16 editions, for £131. The authors received above £1000 from the sale of the work. James was afterwards an occasional contributor to the periodical literature of the day, and author of the humorous theatrical entertainments of Charles Mathews (for which he received £1000). Horace S. wrote several novels—*Brambletye House, Tor Hill,* &c.

SMITH, JOSEPH. See MORMONS.

SMITH, Rev. Sydney, a celebrated wit and humorist, and the original projector of the *Edinburgh Review*, was born at Woodford, in Essex, in 1771. His father was an eccentric English gentleman of moderate independence; his mother was the grand-daughter of a French refugee; and Sydney, it was said, fairly represented both nations. He was educated at Winchester School and New College, Oxford, and having entered the church, became curate of Amesbury in Wiltshire. 'The squire of the parish,' he says, 'took a fancy to me, and requested me to go with his son to reside at the university of Weimar; before we got there, Germany became the seat of war, and in stress of politics, we put into Edinburgh, where I remained five years.' During this time, he officiated in the Episcopal chapel there, and published *Six Sermons*, 1800. In conjunction with a few accomplished literary associates —Jeffrey, Horner, Brougham, Dr. Thomas Brown, Playfair, &c. —S. started the *Edinburgh Review*, the first number of which appeared in October 1802, constituting a new era in the history of periodical literature, and of independent thought and criticism in this country. In 1803, S. removed to London, and was soon popular as a preacher, as a lecturer on moral philosophy (1804—1806), and as a brilliant conversationist, the delight and wonder of society. Church preferment, however, came slowly. In 1806, during the short reign of the Whigs, he obtained from Lord Erskine, when Lord Chancellor, the rectory of Foston-le-Clay, in Yorkshire; some 18 years afterwards, the Duke of Devonshire gave him the living of Londesborough, worth £700 per annum, to hold until Mr. Howard, son of the Earl of Carlisle, came of age. In 1828, Lord Chancellor Lyndhurst presented him to a prebendal stall in Bristol, and enabled him to exchange Foston for Combe Florey, a more desirable rectory in Somersetshire.

In 1831, Earl Grey appointed him one of the Canons Residentiary of St. Paul's and this completed his round of ecclesiastical preferments. He sighed for a mitre, but it never came; and Lord Melbourne is said to have regretted this omission in his career as Prime Minister. The writings of S. subsequent to 1800 were his contributions to the *Edinburgh Review*, which he collected and republished, with other miscellaneous works, in 1839; *Peter Plymley's Letters*, written in 1807, to promote the cause of Catholic emancipation, and abounding in wit and irony worthy of Swift; *Sermons* in two volumes, 1809; *Speeches on the Catholic Claims and Reform Bill*, 1825—1831; *Three Letters to Archdeacon Singleton on the Ecclesiastical Commission*, 1837—1839; *The Ballot*, a political pamphlet, 1837; *Letter to Lord John Russell on the Church Bills*, 1838: *Letters on Railways*, 1842; *Letters on American Debts*, 1843; &c. Though gay, exuberant, and witty to the last, S. suffered from periodical attacks of gout and other complaints, and he died on the 22d of February 1845. Ten years afterwards, his daughter, wife of Sir Henry Holland, physician, published a Memoir of her father with a selection from his letters.

The works of S. were mostly written on temporary topics and controversies, yet they bid fair to take a permanent place in our literature as specimens of clear and vigorous reasoning, rich unctuous humor, and solid good sense. His jokes, exaggeration, and ridicule are all logical, driving home his argument; and his wit was sportive, untinctured with malice.

SMITH, William, called the Father of English Geology, was born in Oxfordshire, 23d March 1769. His profession of land-surveying led him to geological observation; and in 1794 he began his map of the strata of England, and became the founder of stratigraphical science. His epoch-making Geological Map of England (see Geology) was published in 1815. He published numerous other geological maps, received many honors, and died at Northampton, 28th August 1839.

SMITHFIELD, a noted cattle-market in London, was in the 12th c. an open spot which served the citizens as a playground and a place for a stroll. Being a little north of Newgate, and west of Aldersgate, it was outside the city walls. It was in S. that the rebel Wat Tyler met his death in 1381. Several noted tournaments were held here; and the place is associated with trials by battle, the burnings of martyrs, public executions during many centuries, and a variety of incidents connected with the history of the metropolis.

The most celebrated fair in England, Bartholomew Fair (q. v.), was always held in Smithfield.

A cattle-market was held in S. at least seven centuries ago, for Fitzstephen mentioned it in 1150. The corporation had official control over the market for more than 500 years, dating from 1345; and the city authorities have never to this day relaxed their hold over the one only live-cattle market in the metropolis. At one time, there was a project for removing the market to a field near Sadlers' Wells, at another, to a spot near the north end of Gray's Inn Lane; while a spirited projector spent £100,000 in building a new market at Islington; but powerful influences prevented the removal of the cattle-market until 1855.

The last market-day in the old spot was on June 11th in that year; after which, the trade was transferred to the large and very complete establishment built by the corporation at Pentonville. For several years after this, S. was practically useless. In 1860, however, the corporation obtained an act for erecting market buildings on the site of S., and the first stone of a magnificent Dead-meat Market, from the designs of Mr. Horace Jones, the city architect, was laid in June 1867. The building, which was formally opened in November 1868, is 636 feet long, by 246 broad, is traversed by numerous avenues, and has about 200 shops for dealers in meat, which is partly country-killed. This arrangement has enabled the city authorities to abolish Newgate Market, which had become a serious obstruction to city traffic. Under the market, three railways sunk deeply below the ground-level, traverse the area—one going eastward to Aldersgate and Finsbury, one southward to Ludgate and Blackfriars, and one north-westward to King's Cross and the north of London. Near the middle of S. is a circular spiral road descending to an underground railway goods-station. The remainder is laid out in well-paved carriage and foot ways with a small ornamental green or garden, including paths, seats, and a drinking-fountain. There is also a new market for poultry, butter, cheese, pork, &c., distinct from the meat-market. The extensive new works and alterations have greatly improved the appearance of S., and increased its salubrity.

SMITHSO'NIAN INSTITUTE, at Washington, District of Columbia, U. S., was organized by act of Congress in 1846, in accordance with the will of James Smithson, who bequeathed the reversion of an estate amounting to 515,169 dollars to the United States of America, to be devoted to 'the increase and diffusion of knowledge among men.' He was an Englishman, a natural son of Hugh, third Duke of Northumberland, and Mrs. Elizabeth Macie, a niece of Charles, Duke of Somerset. He devoted his life to scientific pursuits, especially to chemistry, and died at Genoa in 1829. The Institute is governed by regents appointed by the Federal government, and has erected a spacious edifice, with museum, library, cabinets of natural history, and lecture-rooms, which occupies a prominent situation at Washington, the capital of the United States. It receives copies of all copyright books, and exchanges with other countries, and its museum is enriched with the gatherings of national exploring expeditions. A portion of its funds is devoted to scientific researches, and the publication of works too expensive for private enterprise. There are departments of Astronomy, Ethnology, Meteorology, and Terrestrial Magnetism. See *James Smithson and his Bequest*, by Rhees (1881). Among the publications issued are the quarto volumes of the *Smithsonian Contributions to Knowledge*, distributed gratis to libraries; *Annual Reports*, and *Miscellaneous Collections*. The courses of public lectures by eminent scientific men are among the attractions of the American capital.

SMOKE-NUISANCE, in London, is punishable with fine. The act applies to every furnace employed in working engines by steam, and every furnace in any mill, factory, printing-house, dye-house, distillery, bake-house, &c., which is not constructed so as to consume its own smoke, or which is so negligently used that the smoke is not consumed. The penalty is from two to five pounds. The statute only applies to the metropolis and to the river Thames.—In Scotland, a similar act is not confined to the Scotch metropolis.

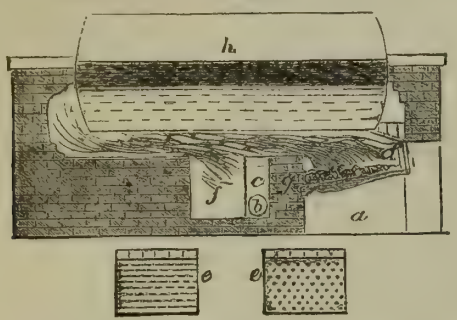
Large consumers of fuel are naturally more anxious about how it can be best burned economically than about how the escape of smoke into the atmosphere can best be prevented. The two questions are not at all the same, although plans may be devised which will accomplish both objects at the same time. Thus with ordinary bituminous coal not only may the volatile hydrocarbons which sometimes yield twenty per cent. of the heating-power pass up the chimney unburned, but nearly two-thirds of the coal may be wasted by the conversion of the carbon into carbonic oxide instead of carbonic acid—that is, if the carbonic oxide escapes as such—and yet no smoke may appear. At the same time, it is the fact that the most complete combustion of the coal insures there being no smoke.

There is a great difference of opinion even about the apparently simple question of how the coal should be laid on the furnace bars. The late Professor Macquorn Rankine and others, reasoning on theoretical grounds, say that the fresh coals should be laid on the front of the fire; whilst Dr. Anderson, late of the Woolwich Arsenal, judging from great practical experience, says that, on the contrary, they should be mainly piled up at the back of the fire. Mr. Wye Williams again, whose name is so famous in connection with such questions, asserts that the coal is best spread evenly over the furnace bars.

Whether the fuel is heaped at the front, at the back, or spread uniformly over the fire, the end in view is the same. It is to secure that the volatile hydrocarbons are burned, and that carbon is converted into carbonic acid, and this can only be done when these gases are conducted over a hot portion of the fire with a sufficient supply of air. If the fresh coal is laid on the front, that of a

previous charge having been pushed inwards, the coal vapors will of course pass over the thin layer of burning fuel at the back, and be more or less burned. When on the other hand, the fuel is kept banked up at the back (that is at the bridge), and spread evenly over the rest of the grate, although a little smoke may be given off at first, it would nevertheless appear that by this plan the mass of incandescent fuel at the bridge is yet more effectual in burning these vapors. The balance of opinion would, however, seem to be in favor of the method of rapid, thin, and uniform spreading of the coal over the grate, care being taken that no part of the furnace bars are left bare.

With regard to the admission of air to the furnace, it is necessary, in order to obtain the best result, that it be admitted through small orifices, and at such a point or points where the temperature is sufficiently high for the combustion of the coal vapors, and that it be so regulated that heat is not uselessly absorbed by an excessive supply. It is of course also necessary to have sufficient air passing up between the furnace bars to burn the non-volatile coke. The arrangement recommended by Mr. Wye Williams



will be understood by the help of the annexed drawing, which represents one of his furnaces under a boiler *h*. The fire is fed, as usual, through the door at *d*; it slopes downward to the bridge *g*, which rises much above the firebars, so that the flames have to pass over it. The bridge consists of two parts, the solid masonry or brickwork, *g*, and the chambered portion behind it, *c*, called the distributer. Into this a tube, *b*, opens, through which a supply of atmospheric air enters, and becoming heated, passes through a number of plates with slits, or with perforations as shown in *ee'*, into the mixing-chamber, *f*; here the heated air enters into combustion with the carbon in the smoke-laden flame, deprives it of that element, and greatly increases the heat by its combustion.

Smoke prevention arrangements may be classified as follows: I. Apparatus for the regular addition in small quantities and uniform application of the fuel to the fireplace of the furnace. The chief kinds are: (1.) A hopper kept charged with small coal or slack, and feeding a rapidly rotating horizontal disc. (2.) A hopper and rollers to reduce the size of the coals, and a screw spreader for throwing them on the fire. (3.) An under grate stoker, which feeds a circular furnace by causing the fresh coal to pass from below through a central orifice into the middle of the incandescent fuel. (4.) A hopper and traveling furnace bars. II. Arrangements for the admission of air above as well as below the furnace bars. This is usually done either by means of air-holes with slide or slides to cover them; or opening and shutting slits in the furnace door or above it. Another plan is to have a valve at the further end of tubular flues in the furnace to regulate the admission of air. In one or two instances a clockwork arrangement has been introduced for gradually closing the air inlets in the furnace doors after firing.

SMOKE-STACK, in a steam-vessel, is the group rising above the deck, and comprising the Funnels (q. v.), and the several escape-pipes for the steam, which are beside it. In ships-of-war, all these are frequently made telescopic, that they may be drawn down out of danger in action or in a strong head-wind.

SMOLE'NSK, a government of European Russia, bounded on the east by the governments of Moscow and Kaluga. Area, 21,554 sq. miles. Pop. (1880) 1,223,890. S., which is watered by the Dnieper, Dvina, Gshat, Oka, Iput, &c., is one of the most fertile provinces of the empire, and produces great quantities of corn, hemp, and flax. Extensive forests yield splendid timber and mast. The rearing of swine is much followed. Manufacturing industry and export trade are both largely expanding.

SMOLENSK, a fortified town of Russia, capital of the government of the same name, is picturesquely situated on a range of steep declivities overlooking the river Dnieper, 250 miles west-south-west of Moscow. It is one of the oldest towns in the empire, having been a place of note in the 9th c., is surrounded by massive walls (with 17 towers), and has three cathedrals, about 32 churches, and several monasteries, together with a diocesan seminary, a gymnasium, a military school for nobles, hospitals, &c. S. carries on manufactures of linens, soap, leather, and carpets, and a considerable export trade in corn and flax. Pop. 1880) 24,350. S. is historically notable as the scene of a bloody repulse of the Russians, under Barclay de Tolly and Prince Bagration, by Napoleon, August 17, 1812, when on his march for Moscow.

SMOLLETT, TOBIAS, an eminent British novelist, born in the year 1721, was descended from an old and distinguished family in Dumbartonshire. His grandfather, Sir James Smollett of Bonhill, was one of the commissaries or consistorial judges of Edinburgh, and sat in the Scots parliament as representative of his native county. Had the novelist survived about four more years than the term of his too short life, he would, as heir of entail, have succeeded to the ancestral estate in the beautiful vale of Leven. He lost his father while very young; but he was well educated, and afterwards apprenticed to a surgeon in Glasgow. He is said to have wished to enter the army, and being disappointed, to have avenged himself on his grandfather, who thwarted his inclinations, by describing Sir James under the unamiable character of the old Judge in *Roderick Random*. This is related by Scott and all the biographers, but it must be wrong; for Sir James, the grandfather, died in 1731, when Tobias was only in his tenth year. The duty of attending to the education and settlement of the youth would naturally devolve on his widowed mother and on the Laird of Bonhill, his cousin.

It is certain, however, that S. inherited no fortune; and in his 18th year, he went to London with a tragedy which he had written on the assassination of James I. of Scotland, and which he trusted would lead to distinction, if not wealth. He was grievously disappointed, and was glad to accept the post of surgeon's-mate on board one of the ships in the unfortunate expedition to Carthagena, in 1741. He soon quitted the service in disgust, although not before he had seen enough of naval life and character to be of inestimable value to him as a novelist; and returning to London, he commenced, and for the remainder of his life followed, the profession of an author. He made, indeed, repeated attempts to obtain practice as a physician, and in 1750, got a diploma of M.D. from Aberdeen; but his hasty irritable temper and independent spirit, joined to his natural propensity to satire, were fatal to his hopes. Even his literary career was a ceaseless warfare. In 1748, in his 27th year, he produced his *Roderick Random*, which was read with the utmost avidity, and seemed at once to place its author very near, if not in the actual rank of Fielding as a novelist. In 1751, appeared *Peregrine Pickle*, a more ambitious and not less successful work; and in 1753, *Ferdinand Count Fathom*, an inferior production, though containing scenes of striking adventure and eloquent description. S. next translated *Don Quixote* (1755), in which, it is admitted, he was surpassed by Motteux and Jarvis. He then undertook the editorship of a new Tory journal, *The Critical Review*, which was the most unfortunate of all his engagements, as it involved him in endless quarrels and personalities. For one article, an attack on Admiral Knowles, he suffered three months' imprisonment, and was fined £100. In 1758, he published his *History of England*, 4 vols. quarto—a history from the descent of Julius Cæsar to the treaty of Aix-la-Chapelle, in 1748, but which was begun and completed in 14 months, realizing for its author a sum of £2000. Though superficial and inaccurate, this history has passages of fine animated writing and masterly delineation of character.

We next find S. involved in political controversy with Wilkes and others, and defending Lord Bute's administration; but he wanted tact and temper for work of this description, and reaped no laurels as a politician. Another novel appeared in 1760—1761, *The Adventures of Sir Launcelot Greaves;* in 1766, two volumes of querulous *Travels in France and Italy;* in 1769, *The Adventures of an Atom*, a political satire unworthy of its author; and in 1771, only a few months before his death, *The Expedition of Humphrey Clinker*, the best of all the novels of S.; and in the opinion of Thackeray, one of the very best in the whole range of imaginative literature. Worn out with literary cares, private misfortunes, anxiety, and ill-health, the novelist retired to Italy, and died at Leghorn, October 21, 1771, in the 51st year of his age.

As a novelist, S. is distinguished by his broad humor and burlesque, the great variety of his incidents and characters, and the excellence of his easy, picturesque style of narrative. He is often careless, but rarely dull. He does not indulge in digressions, like Fielding, and though less of a literary artist than his great English rival, his works are read with more intense interest. He had, in fact, greater imagination and poetical sensibility. He added largely to our stock of original characters and humorists—Strap, Tom Bowling, Morgan the Welshman, Lismahago, and Matthew Bramble are still unsurpassed. Delicacy of taste was denied to both Fielding and S., and perhaps the latter is the more gross and sensual of the two. But the novelist lived in a coarse age, and possessed an exuberant fancy. There is a good deal to regret and to condemn; but to an author who has conferred so much true, healthy pleasure and enjoyment on countless generations of readers, forgiveness is easily extended, and is soon lost in admiration.

SMOLT. See SALMON.

SMORZA'TO, or SMORZANDO (Ital. dying away), a musical term, indicating a gradual diminution in tone, till the sound altogether fades away.

SMUGGLING is the offence of importing or exporting goods prohibited, or without paying the duties imposed on goods not prohibited. The offence in general leads to forfeiture of the goods. If goods are imported to defraud the revenue, treble value of the goods is forfeited. Many of the offences connected with smuggling are felonies, and punished with severity under the Customs' Consolidation Act. Where high protective tariffs separate the industry of adjoining countries, smugglers are certain to abound; no prohibitory decrees can keep the goods out. It was in vain that Napoleon fulminated the Berlin and Milan decrees for closing all continental ports against British shipping; British goods were landed at Salonica, passed on horseback through Hungary to Vienna, and thence distributed in all directions. Similarly, French manufactures reached England, often most circuitously: some a year in transit by way of Smyrna; others, *viâ* Archangel, after two years' journey. A vast cost was incurred in England in maintaining a Coast Guard and Preventive Service; but so long as smuggled goods could be sold at much lower prices than those at which they could be lawfully imported, so long would it be absolutely impossible wholly to suppress the traffic. The duties on French goods evaded in 1831, by the aid of smuggling, were estimated at £800,000. The true remedy for smuggling is a free, or, at least, very liberal tariff, without any prohibitive rates. Since the adoption of free trade by Great Britain, its Coast-guard has ceased to have any preventive duties to perform, and has been converted into the far better institution of a defence for the coasts from foreign foes, a reserve of trained men for the sea-service, and last, though far from least, a branch of skilful auxiliaries ready to aid any ship thrown in distress upon the British coast. The leading instance of smuggling, so far as England or Englishmen are concerned, is the great amount of contraband traffic from Gibraltar into Spain.

SMUT, the popular name of certain small fungi of the section *Coniomycetes*, and group or family *Uredineæ*, parasitical on plants, particularly on grasses, and notable for the great abundance of dark-colored spores which they throw off. The name S., although somewhat variously used, is now very generally limited to the genus *Ustilago*, in which the character just mentioned, of the profusion of dark-colored spores, is very remarkable. The name S. is often given to *Ustilago segetum*, or *Uredo segetum*, also called DUST-BRAND, a species very common and destructive, parasitic on wheat, barley, oats, and rye (see ERGOT), at the base of the german and glumes, causing the death of the inner parts of the flower, and then converting the whole into a sooty dusty mass. At first, a fine mycelium alone is seen, which ere long produces spores. There is no disagreeable smell, as in some of the allied fungi. A remarkable kind of S. infests maize, swelling the ears to an enormous size, sometimes even a foot in length. No remedy or preventive is known for smut. It does not seem to be communicated through infected grains; but perennial plants attacked by fungi of this kind remain diseased in subsequent years. Some kinds of S. attack other parts of plants than those chosen by *Ustilago segetum*. The reeds of the fenny districts of England are often much affected by a species (*Ustilago typhoides*), which much impairs their quality for all purposes, and has the more remarkable property of greatly affecting the health of the laborers employed in cutting and sorting them, producing not only a sense of oppression, but swelling of the head, the formation of vesicles, and inflammation of the bowels, besides other smyptoms, such as are often produced by cantharides. Mr. Berkeley says: 'The subject is worth attention, not only as curious in itself, but because it is very possible that, like the ergot, the fungus may afford a valuable addition to the Pharmacopœia.'

SMY'RNA, one of the most ancient and important cities of Asia Minor, and the only one of the Greek cities on the western coast which has retained its name and importance to the present day. The early history of S. is very obscure: varying accounts represent it either as originally an Ionian colony, or as having been at first an Æolian city, which, by an act of treachery, fell into the hands of Colophonian (Ionian) exiles, and subsequently, about 700 B.C., formed part of the great Ionian League. This earliest city of S., known among the Greeks as 'Old Smyrna,' was situated on the banks of the little river Meles, on the north-east side of the Hermæan Gulf, now the Gulf of Smyrna, and claimed the honor of being the birthplace of Homer; and here, near the source of the river, a grotto was shown, in which he was said to have composed his poems. This old city of S. was destroyed, we are told, by the Lydian king Ulyattes, and the place remained deserted and in ruins till after the Macedonian conquest, when the city was rebuilt at the distance of between two and three miles south of its original site. This city of 'New Smyrna' was founded by Antigonus, and enlarged and embellished by Lysimachus; it was laid out with great magnificence, and adorned with several fine buildings, among which was the *Homereum*, where the poet was worshiped as a hero. The city had an excellent harbor; and from its admirable situation, soon became one of the finest and most flourishing in the world. In the early history of Christianity, S. holds a distinguished place as one of the Seven Churches addressed in the Apocalypse, and as the scene of the labors and martyrdom of its first bishop, Polycarp. After various vicissitudes during the middle ages, it fell finally into the hands of the Turks, in whose possession it has since remained—the most flourishing city of the Levant.

The modern city of S. (Turkish *Izmîr*) occupies the site of New S., being built partly on the plain at the head of the gulf, partly on the declivity of a hill, the ancient Mons Pagus, and, from the sea, has an attractive appearance. There are some good quays, and some handsome buildings of stone; but the greater part consists of low wooden houses, for the most part of one story high; and the streets, with a few exceptions, are ill-paved, narrow, crooked, and dirty. The city, however, in these respects is better than most other Turkish towns, and improvements have of late years been made. The pop. is estimated at 150,000; of whom 80,000 are Turks, 40,000 Greeks, 15,000 Jews, 10,000 Armenians, and 5000 Franks. As is usual in Turkish towns, each people has its separate quarter. S. contains several Greek, Armenian, Roman Catholic, and Protestant churches, and about 20 mosques. There are six journals published here in five different languages. The harbor is excellent; ships of large burden anchor close to the quays; and the trade is most important and extensive. A railway, 81 miles long, constructed mainly with English capital and by English engineers, has been recently opened to Aidin, an important inland commercial town, and is now in operation. Another railway, extending 61 miles inland (to Cassaba), was finished in 1866, and afterwards extended to Philadelphia (Alasher). The chief imports are woollen, cotton, and silk fabrics, iron, tin, lead, copper, steel, zinc, glass, and hardware goods, coffee to the amount of 6,000,000 lbs. annually, sugar, spirits, spices, indigo, cochineal, &c. The exports consist of wool, cotton, silk, carpets, hides, opium, madder, copper, valonia, olive-oil, drugs, and gums, figs, raisins, and many other articles. Upwards of 2500 vessels (of some 1,500,000 tons) annually enter and clear the port; and in the ten years 1870—1880 the annual value of the imports was £3,800,000, and of the exports £4,200,000.

S. is regularly visited by the ships of the French, Austrian, and Russian Steam-navigation Companies, and by traders from Great Britain and other countries. It suffered severely from fire in the summers of 1841 and 1845, and has been often ravaged by earthquakes and the plague. The city and its territory are governed by a pasha. Of the ancient cities, not much remains. Some slight ruins mark the site of Old Smyrna. Of New S., some remnants of the massive walls on the hill south-east of the city are still to be seen; the site of the Stadium in which Polycarp is supposed to have suffered martyrdom, is pointed out; there are some fragments of the ancient theater, and columns belonging to a temple; and numberless architectural fragments have been built into the walls of the Turkish town, or used in the construction of graves in the large Turkish cemetery.

SMYRNA, GULF OF, an inlet of the Ægean Sea, on the west coast of Asiatic Turkey, is so called from the city of Smyrna (q. v.), which stands at its head. It is 40 miles long, is about 20 miles in greatest breadth, and contains several islands. Its waters are deep, and it affords good anchorage.

SNAIL (*Helix*), a genus of gasteropodous molluscs of the family *Helicidæ*, having generally a sub-globose, sometimes a depressed, spiral shell; the mouth of the shell more or less encroached upon by the last whorl but one, strengthened with an internal thickened rib, its edges more or less reflexed; the *foot* of the animal long, and pointed behind; the tentacles four, the lower pair much smaller than the upper; the tongue armed with many—often from 100 to 200—longitudinal rows of teeth. The species are very numerous, more than 1400 having been described; besides fossil species, of which also there are many. Some of the groups have been constituted into separate genera by recent authors, but all retain the popular name S., which is indeed often extended to all the *Helicidæ*.

As an instance of the general distribution of snails, it may be noticed that *Helix aspersa*, one of the common garden snails of Britain, is found very generally throughout Europe, great part of Asia and the north of Africa, and in South America.—Snails feed chiefly on vegetable substances, although they are very indiscriminate in their appetite, and even devour the dead of their own kind. The mischief which they do to garden-crops is too well known; and gardeners lay down cabbage-leaves and the like to attract them, in order that they may be destroyed; any greasy substance increasing the attractiveness of the bait.—Snails delight in warm moist weather; in dry weather, their chief time of activity is during the night, and they

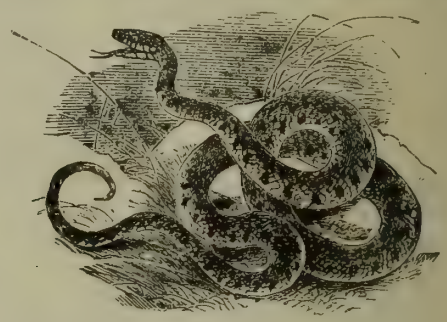
hide themselves by day; but after rain, they come forth at any hour in quest of food. At the approach of winter, or in very dry weather, they close the mouth of the shell with a membrane (*epiphragm*), formed by the drying of the mucous substance which they secrete, and become inactive and torpid. Some, as the Edible S. (*H. pomatia*), make a succession of such membranes; the outer one of which is also strengthened by a quantity of calcareous matter, the secretion being at first a white viscid fluid,

Common Snail and Eggs (*Helix aspersa*):
1, Eggs; 2, Appearance when newly hatched; 3, Slightly advanced stage; 4, Mature Snail.—Copied from Morton's *Cyclopædia of Agriculture*.

but quickly hardening like plaster of Paris. When this is to be removed, a fresh secretion of fluid mucus softens it at the edges. Snails retreat into crevices for the winter, or into holes which they make in the earth, and which are roofed over with earth, dead leaves, &c., agglutinated by secreted mucus.—Snails are hermaphrodite, but mutual impregnation takes place, and when they are about to copulate, they excite each other by pricking or even piercing with a sharp calcareous glass-like style, affixed to a peculiar muscular sac which serves for its protusion, and which is produced by recent secretion, not being found in them on dissection, except at the season of reproduction. Extraordinary as this circumstance is, it has been the subject of much exaggeration, and in works on natural history not of very old date, we read of snails throwing darts (*spicula amoris*) at each other, all which appears to be merely fabulous, although it is probable that the calcareous style may be often broken off in its use.

The eggs of snails are round, and enveloped in a skin; they are generally deposited in little clusters. The eggs of the common garden-snails of Britain are about the size of peas, and are deposited just under the surface of the soil.—Snails possess in a very high degree the power of repairing injuries, not only of the shell —although the removal of the whole shell is fatal to them—but also of the soft parts. When the tentacles are cut off, they grow again; and even if the head is cut off, a new head is produced.—We do not think it necessary to describe any of the common British species, as there is nothing of peculiar interest connected with any of them; and the rarer and smaller species have still less claim to notice. The EDIBLE S. (*H. pomatia*) of the south of Europe is the only one that deserves to be particularly mentioned. It is found in the chalk and oolite districts of the south of England, where it is said to have been introduced from the continent in the 17th c.; but this is very doubtful. It has a shell about two inches in diameter and two inches in height, whitish or pale tawny, with four darker bands, often not very distinct. It was much esteemed as an article of food by the ancient Romans, who fattened their snails in enclosures (*cochlearia*) made for the purpose, feeding them delicately on meal and boiled wine. It is still in much esteem for the table in various parts of Europe, and is occasionally used in England. Nor is it the only species so used; the common garden-snails are probably equally good, although not so large, and 'the glassmen at Newcastle once a year have a snail-feast; they generally collect the snails themselves in the fields and hedges the Sunday before the feast-day.'—Turton's *British Land and Fresh-water Shells*. Snails of different species are also an article of exportation on a small scale from England to the United States, packed in old casks, in which they are conveyed very well, fixing themselves one upon another to the cask, and leaving a vacant space in the center. Snails boiled in milk are popularly regarded as a remedy for diseases of the chest, and for this purpose they are brought to Covent Garden market. If any benefit results from the use of them, it is probably due to their nutritious qualities.—Some of the tropical species of Helix are very large, and some have very beautiful shells.

SNAKE, a term synoymous with serpent.—The name COMMON S. is very generally given in England to a species very abundant in most parts of that country, and throughout Europe from the south of Scandinavia to the Mediterranean, although there is only one doubtful instance of its having been found in Scotland. Its range extends also over great part of the north of Asia. This species (*Natrix torquata* or *Tropidonotus natrix*) is also known as the RINGED S. and the GRASS SNAKE. It belongs to the family *Colubridæ*, and to a section of it which some naturalists constitute into the family *Natricidæ*. It grows to the length of four and even five feet, although specimens exceeding three feet are rare. The female, as in serpents generally, is much larger than the male. The head is ovate, the muzzle rather narrow, the back part considerably broader than the neck; the body thickens towards the middle, and again tapers towards the tail, which is about one-fifth of the entire length, tapering to a rather sharp point; the gape is wide; the upper part of the head covered with large plates; the scales of the back have an elevated keel; those of the sides are larger, the keel merely rudimentary; the belly is covered with broad oblong plates; the under part of the tail has plates arranged in two rows. The teeth are very small, directed backwards, and arranged in two rows on each side of the jaws. The upper parts are grayish brown, tinged with green; at the back of the head are two crescent-shaped bright yellow spots, forming a kind of ring or collar; immediately behind these are two broad black spots, sometimes confluent. Two rows of small black spots are arranged alternately down the back, and larger ones at the sides; but these vary much in size and other particulars. The belly is pale lead color, often marbled with black. The outer skin is changed at intervals varying according to the weather and other circumstances. Mr. Bell says: 'I have known the skin shed four or five times during the year. It is always thrown off by reversing it; so that the transparent covering of the eyes, and that of the scales also, are always found concave in the exuviæ.



Common, or Ringed-Snake (*Natrix torquata*).

'Previously to this curious circumstance taking place, the whole cuticle becomes somewhat opaque, the eyes are dim, and the animal is evidently blind. It also becomes more or less inactive, until at length, when the skin is ready to be removed, being everywhere detached, and the new skin perfectly hard underneath, the animal bursts it at the neck, and creeping through some dense herbage, or low brushwood, leaves it attached, and comes forth in far brighter and clearer colors than before.' This snake is partial to damp situations, and often enters water, in which it swims with great ease, moving with singular gracefulness. It sometimes remains at the bottom for a considerable time. It sometimes climbs trees, its body, when ascending the stem, being 'straight and rigid as a stick.' See SERPENTS. It is very voracious; its food consists of frogs, small birds and quadrupeds, &c. Its teeth being incapable of tearing, cutting, or masticating food, the prey is always swallowed entire and living. Mr. Bell heard a frog emit a cry some minutes after it had been swallowed by a snake. The S. has no poison-fangs. It has another kind of defensive armor, in certain glands, which emit a volatile substance of most offensive and penetrating odor, which, like that of the skunk, can hardly be removed from the skin or clothes. No such odor is emitted except in moments of irritation or other passion. The Common S. is oviparous: its eggs—usually about fifteen or twenty in number, whitish, with a parchment-like skin, and united into a string by a glutinous substance—are deposited in moist and warm situations, often in dunghills. The mother is said sometimes to coil herself around them, but generally leaves them unregarded. This snake is capable of being tamed, and becomes familiar with those who are kind to it, whilst the approach of a stranger, or of a dog or cat, alarms it, and causes an emission of stench. In winter, it seeks some refuge from severe cold, and becomes lethargic or dormant. Large numbers of snakes often take refuge in one hole; but seldom so many as in an instance recorded by Dr. Carpenter, in which about 1300 were found in an old lime-kiln.

Much interest was excited in 1862 by the discovery in England of a species of snake, *Coronella lævis* (see CORONELLA and SERPENTS), previously unobserved in Britain, but common in the middle and south of Europe, and sometimes distinguished by the name of AUSTRIAN S., sometimes by that of SMOOTH S., none of the scales being ridged or keeled, as in the Common Snake. It inhabits much drier situations than those affected by the Common S., where it is often found in company with the Sand Lizard, situations more resembling those in which the viper is found.

This snake is also more similar to the viper in form and appearance than the Common S., and these circumstances have probably led to its being often mistaken for the viper, and its existence in England remaining unnoticed so long. It attains a length of about two feet; is of a shining brown color, ornamented with checkered irregular patches of black; a yellow mark on the back and sides of the head; the lower parts yellowish, with square black spots. The head is not flattened, as in the viper, but is narrowed in a similar way towards the neck; there is much difference in the plates of the head; the yellow mark on the head is a very characteristic distinction, and the back does not exhibit a broad zigzag pattern, as in the viper. Unlike the Common S., the *Coronella lævis* is ovoviviparous, the eggs being hatched within the mother.

SNAKE-BIRD. See DARTER.

SNAKE-BITES. See VENOMOUS BITES and STINGS.

SNAKE-EEL, the popular name of the fishes forming the family *Ophisuridæ* of some naturalists, included by others, with all the eels, in the family *Murænidæ*, and distinguished by the want of a tail-fin, and the tail ending in a conical point like that of a serpent. They are inhabitants of the seas of warm climates. One species, *Ophisurus serpens*, is found in the Mediterranean. It attains the length of about six feet, and the thickness of a man's arm; is brown above, silvery beneath, and has a slender and pointed snout.

SNAKE RIVER, also called LEWIS' FORK, is the great southern branch of the Columbia (q. v.).

SNAKE-ROOT. See POLYGALA and ARISTOLOCHIA.

SNAKE-STONES, small rounded pieces of stone or other hard substance, popularly believed to be efficacious in curing snake-bites. A belief in their efficacy has been long and very widely diffused, and probably extended to Britain and other western parts of the world from the East. Small perforated balls and rings of various kinds of stone, ivory, &c., strung together like beads, were formerly used as snake-stones in Scotland, being given to cattle to chew when they were bitten by vipers. Of course they could only be expected to act as a kind of charm. Many of the snake-stones used in India and the further east seem to be of no greater value. Some of them, however, appear to be really efficacious, being applied to the wound and absorbing blood from it with the poison before it has entered the system. Remarkable instances are related of speedy cures thus effected. The snake-stone adheres for a short time to the wound, and then falls off. The wounded limb is meanwhile rubbed downwards. Two small snake-stones, each the size of a large pea, brought from India, and which were known to have cured a man bitten by a cobra, were found by Mr. Quekett to be composed of some vegetable matter. Another, also known to have cured a cobra's bite, having been brought from Ceylon by Sir James E. Tennent, was examined by Mr. Faraday, and was deemed by him to be 'a piece of charred bone, which has been filled with blood, perhaps several times, and then carefully charred again.'—See Buckland's *Curiosities of Natural History*, and Tennent's *Ceylon*, vol. i.

SNAKE-WEED, another name of BISTORT (q. v.).

SNAKE-WOOD, another name of LETTER-WOOD (q. v.).

SNAPDRAGON (*Antirrhinum*), a genus of plants of the natural order *Scrophulariaceæ*, consisting of annual and perennial herbaceous plants, chiefly natives of the temperate parts of the northern

Snapdragon (*Antirrhinum majus*).

hemisphere. They have the calyx 5-parted; the corolla swollen at the base, but without a spur, and *personate* (Lat. *persona*, a mask), i. e., its mouth closed by the pressure of the lower against the upper lip; and the fruit is a 2-celled oblique capsule, opening by three pores at the apex. The English name refers to a peculiarity of the corolla, the lower lip of which, if forcibly parted from the upper, so as to open the mouth, shuts with an elastic spring or snap. Some of the species have very pretty flowers. *A. majus* has long been a favorite in our gardens, in which there are many fine varieties of it.

SNAPHAUNCE, an old musket of the 17th and first half of the 18th c., called also Asnaphan. See LOCK.

SNEE'HÄTTEN. See NORWAY.

SNEEK, a prosperous trading and manufacturing town in the Netherlands, province of Friesland, 13 miles south-south-west of Leeuwarden. It is built in the form of an irregular triangle, has three canals, and good water-way to the sea. Rich meadow-lands, in some places tending to be marshy, surround the town, and in the neighborhood is a considerable lake called the Sneekermeer. Pop. (Jan. 1, 1875) 9654; 6972 Reformed, and 1450 Roman Catholics, the remainder chiefly Baptists, except 150 Jews. S. is the largest butter and cheese market in the province; the quantity sold reaching 5,000.000 lbs. of butter, and 2,250.000 lbs. of cheese annually. The principal buildings are the Reformed Church, Town-house, Baptist Church, and Jewish synagogue.

SNEEZE-WOOD (*Ptæroxylon utile*), a tree of the natural order *Sapindaceæ*, a native of South Africa, common in the eastern districts of Cape Colony. The timber rivals mahogany in beauty, takes a fine polish, is very solid, strong, and durable. It receives its English name, and its Dutch name, *Nieshout*, from the sternutatory properties of its sawdust, by which workmen are often much annoyed.

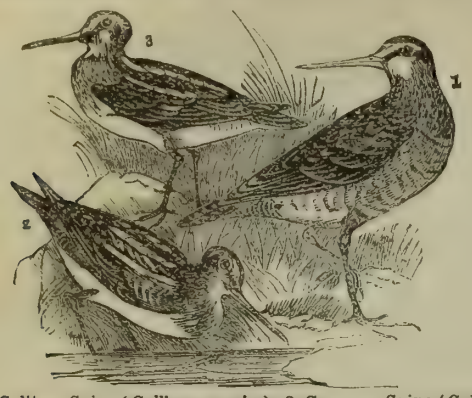
SNELL EXHIBITIONS. These exhibitions were founded in the year 1677 by John Snell of Uffeton, in the county of Warwick, for the purpose of educating Scottish students at the university of Oxford. Snell was born in the parish of Colmonell, in Ayrshire, in 1629, and entered the university of Glasgow, in 1644. He afterwards removed to England, where, after holding several offices of a legal nature, he was appointed seal-bearer to the Court of Chancery. He died at Holywell, near Oxford, in 1679, leaving his estate of Uffeton, near Leamington, to trustees (the Vice-chancellor of the university of Oxford, the Provost of Queen's College, the Master of Balliol College, and the President of St. John's College), for the foundation of the scholarships which bear his name (at present 14 in number). The exhibitions have been the subject of much litigation in the Court of Chancery, and are now administered under a scheme settled in 1861. The exhibitioners are nominated by the college of Glasgow, and receive about £110 annually each during five years. Candidates for these scholarships must have been born in Scotland, or must be sons of fathers born in Scotland, and must have resided for two years at least in Glasgow College, or for one year in that college, and two at least in some other college in Scotland. None are admitted to examination who have completed their 21st year, or have been members of the university of Oxford of more than two years' standing from the day of their matriculation inclusive. Two exhibitioners are nominated annually after public competition. The list of Snell exhibitioners includes not a few well-known names, such as J. G. Lockhart, Sir W. Hamilton, the late Archbishop of Canterbury (Tait), &c.

SNIA'TYN, a town of Galicia, in Austrian Poland, is situated on the Pruth, and was formerly a frontier stronghold. It has tanneries, and a considerable trade in cattle and horses. Pop. (1880) 10,375, among whom are many members of the Armenian Church.

SNIPE (*Scolopax*), a genus of birds of the family *Scolopacidæ* (q. v.), having a very long straight bill, with nasal grooves extending almost to the tip, which expands a little, the upper mandible slightly exceeding the lower in length, the whole bill soft and very sensitive, smooth and shining in the living bird, but soon after death becoming pitted like the end of a thimble by drying. The head is compressed; the eyes large, and placed far back in the head, an evident adaptation to the mode of life, enabling the bird to guard against danger, whilst its bill is plunged in the mud. The feet have three toes before, divided to the base or very nearly so, not edged by membrane, the hind-toe short. The tail is short. The genus naturally divides itself into two sections, sometimes regarded as distinct genera, the first consisting of the Woodcocks (q.v.), to which the generic name *Scolopax* is appropriated; the second containing the species popularly known as Snipes, which receive the generic name *Gallinago*, and are distinguished by their lighter form, by their longer legs, and by having a little of the lower part of the tibia bare.—The COMMON S. (*S. gallinago*, or *Gallinago media*) is about 11 inches in entire length, the bill almost 3 inches. The sexes are alike in plumage, but the female is rather larger than the male. The general color of the upper parts is blackish brown, finely mixed with pale brown and with a rich buff color; three pale brown streaks along the head; the neck and breast pale rust color mottled with black; the belly white. The tail

consists of 14 feathers. The S., when flushed, changes its course several times in a zigzag manner in the air, and then darts off very swiftly, so that young sportsmen find it a very difficult bird to shoot.

The S. makes a very inartificial nest of a little dry herbage, in a depression of the ground, or sometimes in a tuft of grass or rushes. The eggs are four in number, pale yellowish or greenish white, the larger end spotted with brown. This species of S. is plentiful in all the moory and marshy parts of Britain, and gen-



1, Solitary Snipe (*Gallinago major*); 2, Common Snipe (*Gallinago media*); 3, Jack Snipe (*Gallinago gallinula*).

erally throughout Europe, also in some parts of Asia, and it is found in the north of Africa. It breeds in Britain, even in the south of England, although many of the snipes which spend the winter in Britain migrate northwards in spring. The S. is capable of being tamed, and becomes very familiar, but is difficult to keep from the prodigious quantity of worms and other such food which it requires. A tame S. has been known to eat nearly twice its own weight of worms in twelve hours. The S. is in high esteem for the table, and is included amongst game in Britain.—The habits of all the other species of S. correspond very nearly with those of the Common Snipe. The GREAT S., or SOLITARY S. (*S.* or *G. major*), is comparatively a rare bird in Britain, but abounds in the extensive marshes of continental Europe, and is found also in Asia. Its entire length is about 12½ inches, the bill not quite so long in proportion as that of the Common Snipe. There are 16 feathers in the tail.—The JACK S., or JUDCOCK (*S.* or *G. gallinula*), the smallest of the British species, is like the Common S. in plumage. It is common in Britain, but mostly as a winter visitant, and is found also, during summer or winter, in most parts of Europe and of the north of Asia.—North America has a number of species. The COMMON AMERICAN S. (*S.* or *G. Wilsoni*) is about equal in size to the Common S. of Europe, and much resembles it also in plumage. The tail has 16 feathers. This species is abundant in summer in the northern parts of the United States and in Canada, in the more southern states in winter. It is in much request for the table, and is often caught in snares.—Snipes are found also in other parts of the world. The name S. is extended in popular usage to include the genus *Macrorhamphus*, in which the outer toes are connected at the base by a membrane. In other characters, as well as in plumage and habits, the similarity to the true snipes is very great. The RED-BREASTED S., or BROWN S. (*M. griseus*), of North America has been occasionally seen in Britain and in Scandinavia. In size it is nearly equal to the Common Snipe.

SNIPE-FISH. See TRUMPET-FISH.

SNI'ZORT, LOCH, a large and picturesque inlet of the sea, in the north-west of Skye (q. v.), between Totternish Point and Vaternish Point. At its head, the loch is only a few furlongs broad; but it gradually expands, and at its entrance the breadth is over 7 miles. It is 13 miles long.

SNORRI STURLESSON, a learned historian, and a distinguished Icelandic politician, was born in 1178 at Hvamma in Iceland where his family, who traced their descent to the ancient kings of Norway and Sweden, had been settled since the early colonization of the island. S. S. was placed at an early age under the care of John Loptson, the grandson of Sæmund Sigfusson, the learned compiler of the old Edda, by whom he was instructed in the history, mythology, and poetry of the North, as well as in classical literature. By his marriage, at the age of 26, with a rich heiress, and the speedy death of his father, S. S. early attained a position of wealth and influence, and by the free choice of the people, was elected supreme judge, or chief magistrate of the island. In this post, he was distinguished for his profound knowledge of the laws and civil institutions of his native country; but his ambition, avarice, and love of intrigue embroiled him personally in sanguinary feuds, and contributed to hasten the destruction of Icelandic independence. His love of intrigue led him to take part in the intestine troubles of Norway, and thus drew upon him the suspicion and ill-will of the Norwegian king, Hakon, who sent secret instructions to Iceland for his arrest, or, if need be, his assassination. The king's intentions were carried out to their fullest extent; and his numerous enemies joining together in a plot against him, S. S. was attacked in his own house, and murdered in the year 1241.

S. S. was a poet of no mean order, and composed numerous *drapas*, or laudatory poems, on the kings and jarls at whose courts he sojourned. His great work is the *Heimskringla*, or Mythic Ring of the World, in which he records the history of the kings of Norway from the earliest times to the death of Magnus Erlingsson, in 1177; and which he compiled from ancient genealogical tables and other documents. It was translated into Danish about 1559 by Peder Clauson, and published first by Olaf Worm (Cop. 1633). This translation has been republished in more recent times by Gruntvig (3 vols., Cop. 1818—1822) and others. German, Swedish, and Latin versions have also been executed. S. S. is believed to have had a share in collecting and arranging the songs of the elder or poetic Edda (q. v.), and to have contributed very materially towards the compilation of the Skalda and other parts of the younger or prose Edda.

SNOW is the frozen moisture which falls from the atmosphere when the temperature is 32° or lower. It is composed of crystals, usually in the form of six-pointed stars, of which about 1000 different kinds have been already observed, and many of them figured, by Scoresby, Glaisher, and others. These numerous forms have been reduced to the following five principal varieties.—1. Thin plates, the most numerous class, containing several hundred forms of the rarest and most exquisite beauty (figs. 1 to 6). 2. A

Fig. 1. Fig. 2. Fig. 3. Fig. 4.

spherical nucleus or plane figure studded with needle-shaped crystals (fig. 8). 3. Six or more rarely three sided prismatic crystals. 4. Pyramids of six sides (fig. 9). 5. Prismatic crystals, having at the ends and middle thin plates perpendicular to their length (fig. 7). The forms of the crystals in the same fall of snow are generally similar to each other. The crystals of hoar-frost being formed on leaves and other bodies disturbing the temperature, are often irregular and opaque; and it has been observed that each tree or shrub has its own peculiar crystals.

Snow-flakes vary from an inch to $\frac{7}{100}$ths of an inch in diameter, the largest occurring when the temperature is near 32°, and the smallest at very low temperatures. As air has a smaller capacity

Fig. 5.

for retaining its vapor as the temperature sinks, it follows that the aqueous precipitation, snow or rain, is much less in polar than in temperate regions. The white color of snow is the result of the combination of the different prismatic rays issuing from the *minute* snow-crystals. Pounded glass and foam are analogous cases of the prismatic colors blending together and forming the white light out of which they had been originally formed. It may be added that the air contained in the crystals intensifies the whiteness of the snow. See RED SNOW. The limit of the fall of snow coincides nearly with 30° N. lat., which includes nearly the whole of Europe; on traversing the Atlantic, it rises to 45°.

but on nearing America descends to near Charleston; rises on the west of America to 47°, and again falls to 40° in the Pacific. It corresponds nearly with the winter isothermal of 52° Fah. Snow

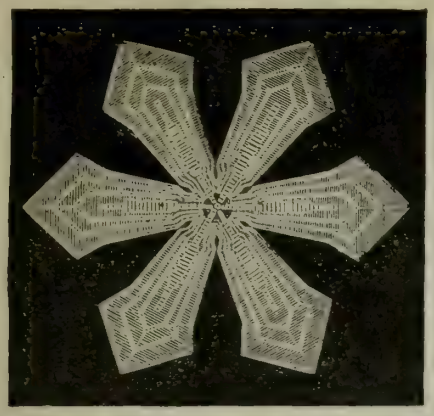


Fig. 6.

is unknown at Gibraltar; at Paris, it falls 12 days on an average annually, and at St. Petersburg 170 days. It is from 10 to 12 times lighter than an equal bulk of water. From its loose texture, and its containing about 10 times its bulk of air, it is a very bad con-

Fig. 7. Fig. 8. Fig. 9.

ductor of heat, and thus forms an admirable covering for the earth from the effects of radiation—it not unfrequently happening, in times of great cold, that the soil is 40° warmer than the surface of the overlying snow. The flooding of rivers from the melting of the snow on mountains in summer, carries fertility into regions which would otherwise remain barren wastes.

SNOW-BALL TREE. See GUELDER ROSE.

SNOWBERRY (*Symphoricarpos* or *Symphoria racemosa*), a bushy deciduous shrub of the natural order *Caprifoliaceæ*, a native of the northern parts of North America, and now very common in British shrubberies. It has simple leaves and small flowers; berries about the size of black currants, remaining on the bush after the leaves, quite white, but uneatable.—The name SNOWBERRY is also given to *Gaultheria serpyllifolia*, a native of the bogs of North America

SNOW-BIRD (*Junco* or *Fringilla hyemalis*), a North American bird of the Finch family (*Fringillidæ*), common from Louisiana to the Fur Countries, in all the eastern parts of North America. The wings are rather short, the tail slightly notched. The whole length is rather more than six inches; the upper parts are lead-color, the lower parts white, the two outer tail-feathers white, the next white margined with black. This bird migrates northwards early in spring, and southwards late in autumn. It is often to be seen in small flocks, visiting barn-yards, and hopping about with the domestic poultry. In cold weather, it retires to holes in hay-stacks. Its song is sweet. From its frequent familiar approach to human habitations, the S. is regarded with favor throughout great part of North America, as the Redbreast is in Britain. In the south, however, it is often brought to market, its flesh being very pleasant. In the western parts of North America, another but very similar species, the OREGON SNOW-FINCH (*F. Oregona*), takes the place of this.

SNOW BUNTING, or SNOWFLECK (*Plectrophanes nivalis*), a bird of the Bunting family (*Emberizidæ*), of a genus distinguished

Snow Bunting (*Plectrophanes nivalis*).

from the true buntings by the long and nearly straight claw of the hind-toe, in this resembling the larks. There is also an approach to larks in habits; there is a similar ease and celerity in running along the ground, and the song is very different from that of any of the true buntings. The S. B. abounds in summer in all parts of the arctic regions, and in winter in more southern countries of Europe, Asia, and America. Linnæus says it is the only living creature that has been seen 2000 feet above the limits of perpetual snow on the mountains of Lapland. Great flocks are seen in Britain, particularly in severe winters, generally frequenting uplands in mild weather, but descending to the low grounds and seashore in hard frosts. Comparatively few visit the south of England. A few remain during summer on the highest mountains of Scotland. The nest is placed on the ground, or in a crevice of a rock. The S. B. is generally very fat, and is highly esteemed for the table. The Greenlanders kill great numbers, and dry them for winter use.

SNOW'DON, a mountain-range in Caernarvonshire, North Wales, stretches in a north-east-by-north direction from a point 5 miles north of Cricceith, near the head of Cardigan Bay, to near Conway; but is broken up by valleys and river-courses into four mountain groups, whose chief peaks are Carnedd-Llewelyn, 3460 feet; Moel-Siabod, 2878 feet; and *Moel-y-Wyddfa* ('the Conspicuous Peak'), the highest mountain in South Britain, 3571 feet above sea-level. Seen from the top, Moel-y-Wyddfa, the 'King of Snowdonia,' appears to send out three ridges, which gradually divide and subdivide, giving birth to numerous valleys and corries. The ascent of the highest peak of S. is effected by tourists from Llanberis (on the north), Beddgelert (on the south), Llyn-Cwellyn (on the west), and Capel Curig (on the east); the first is shortest and easiest; the last is longest, most difficult, but at the same time by far the grandest. The district of 'Snowdonia' was made a royal forest by Edward I. of England, but was disafforested in 1649.

SNOWDROP (*Galanthus*), a genus of plants of the natural order *Amaryllideæ*, of the same tribe with Amaryllis, Snowflake, Crinum, &c. The three outer segments of the perianth spread, so as to make a bell-shaped flower; the three inner are shorter, erect, and notched at the summit. The flowers arise from a spathe. The root is bulbous, and produces two leaves and one single-flowered leafless stem (*scape*). The Common S. (*G nivalis*), a plant too well

Common Snowdrop (*Galanthus nivalis*).

known to need description, is a native chiefly of the south o Europe, growing in woods and pastures. It is found apparently wild in some places both in England and Scotland, but is probably rather naturalized than native, having long been much cultivated in gardens. Another species of S. (*G. plicatus*), with much broader leaves, is found in the south of Russia and in Asiatic Turkey.

SNOW-LINE. The snow-line marks that height above the sea-level below which all the snow that falls annually melts during summer; higher than this lies the region of perpetual snow. No general rule for the height of this line can be given, owing to the different causes which may determine it. These are—the situation of the slope in respect of the sun's rays, and hence, other things being equal, it is higher on the south than on the north side of mountains; the situation with respect to the rain-bringing winds; the steepness of the slope; and the dryness or humidity of the region. The following are the observed heights of the snow-line in English feet, in different parts of the globe:

	N. Lat.	Height.
Spitzbergen	78	0
Sulitelma, Lapland	67	3,835
Kamtchatka	59½	5,249
Unalashka, W. America	56½	3,510
Altai	50	7,034
Alps	46	8,885
Caucasus	43	11,063
Pyrenees	42¾	8,950
Rocky Mountains	43	12,467

	N. Lat.	Height.
North Himalaya	29	19,560
South Himalaya	28	15,500
Mountains of Abyssinia	13	14,065
Purace, Columbia	2½	15,381
	S. Lat.	**Height.**
Nevados of Quito	0	15,820
Arequipa, Bolivia	16	17,717
Paachata, Bolivia	18	20,079
Portillo, Chili	33	1,473
Cordilleras, Chili	42½	6,010
Magellan Strait	53½	3,707

From lat. 0° to 20°, it sinks only a very little; from 20° to 70°, it continues to fall equably; but from 70° to 78°, it sinks with great rapidity. To this general statement there are some important exceptions. It is about 4000 feet higher on the north than it is on the south side of the Himalaya, owing to the greater depth of snow that falls on the south side; to the greater dryness of the climate of Tibet, which increases the evaporation and the heating power of the sun's rays; and to the naked rocks and soil of the north absorbing more heat than surfaces covered with vegetation. It is higher in the center of continents than near the coasts (the rain being less, and the heat greater), as seen on comparing the Pyrenees and Caucasus; and on the east than on the west coasts of continents, which is strikingly illustrated by Kamtchatka (5249) and Unalashka (3510), situated respectively on the west and east coasts of the North Pacific. South of the equator, it rises from 0° to 18° very considerably, and more so on the west than on the east of the Cordilleras, owing to the small amount of rain and snow which falls on the west of these mountains. It is as high in 33° south lat. as in 19° north lat.; but south of this it sinks very rapidly, so that in the south of Chili it is 6000 feet lower than in the same latitude in the Rocky Mountains, and 3000 lower than in Western Europe. The mean temperature of the snow-line varies much from the equator to the pole—from 35° to 20° Fah. In the Alps, it is about 25°; and in Norway, about 23°.

SNOW-SHOES, a species of shoe much used by the Esquimaux, Laplanders, and others who inhabit those regions where snow prevails for a great portion of the year. It consists of a flat frame, of a lanceolate form (see fig.), from 8 to 14 inches in breadth at its widest part, and of great length—sometimes as much as 7, though generally about 4 feet. It is either wholly of wood, or is a wooden frame filled in with wicker-work or thongs, and has cross-straps on the upper surface to attach it to the foot. The broad surface prevents the foot from sinking in the snow.

Snow-shoe.

SNUFF. See TOBACCO.

SNYDERS, or SNEYDERS, FRANCIS, a Belgian artist, celebrated for his powers as an animal-painter, was born at Antwerp in 1579, and was formed in the school of Henry van Baelen. Originally, he confined himself exclusively to painting fruits, and worked with Rubens. In his pictures, with figures by Rubens, Jordaens, Honthorst, and Mierevelt, it is difficult to discover any difference of touch. For Philip III. of Spain he executed several hunting and battle pieces. S. knew how to give expression to the passions of the lower creation, and his bear, wolf, and boar fights are scarcely surpassable. The best specimens of the artist are contained in the galleries of Vienna, Munich, and Dresden, but there are also some fine pictures of his in private English collections. S. died at Antwerp in 1657.

SOAP (Lat. *sapo(n)*, Welsh *sebon*—the Romans considered soap to be a Celtic invention). This well-known material, according to Pliny, first became known to the Romans by their conquest of Gaul. There are some notices of it in the English version of the Bible, but it is believed that the words *borith* and *nether*, there rendered into soap, really mean potash and soda.

The *chemical composition* of soap may be explained as follows: The fixed fatty bodies, stearine, palmitine, and oleine (we do not include margarine, for it is now generally admitted that the fat to which this name was applied is merely a mixture of stearine and palmitine), when heated with alkaline solutions, undergo the remarkable change known under the title *Saponification*, or conversion into soap, during which process the fats yield up a clear viscid liquid, which, from its sweetness, is termed *Glycerine* (q. v.). The nature of this change may be ascertained by decomposing the soap that is thus formed, and which exists as a homogeneous transparent mass, freely soluble in warm water, by the addition of some acid, such as tartaric or hydrochloric, which combines with the alkali, and forms a soluble compound with it. A fatty matter separates in flakes, which melt on the application of heat, and form an oily layer on the surface of the fluid. This substance, when cold, is found to be very different from the original fat. It has acquired a strongly acid reaction, as may be ascertained by applying test-paper to it in its melted state, and it is freely soluble in alcohol, the solution being strongly acid. It at once forms a clear solution in hot alkaline liquids, while the original fat would under similar conditions have formed a milky-looking fluid. It is, in fact, a true *acid*, capable of forming salts, the potash and soda salts being known as *soft-soap* and *hard-soap*, which have been thus generated out of the elements of the neutral fat under the influence of the alkali. Stearine, when thus treated, yields *Stearic Acid* (q. v.); palmitine yields *Palmitic Acid* (q. v.); and oleine *Oleic Acid* (q. v.); while common fat, which is a mixture of the three above-named fats, affords, on saponification with an alkali, and subsequent decomposition of the soap, a mixture of the three fatty acids.

The term soap is sometimes extended in meaning, so as to include compounds of the fatty acids with other bases besides the alkalies, e. g., lime, baryta, magnesia, &c.; but these compounds being insoluble are inapplicable to the purpose of cleaning. The true soaps owe their cleaning power to their solubility, and their attraction for the matters that ordinarily constitute 'dirtiness.' The presence of a portion of free alkali increases the detergent power, especially in the case of greasy matter.

Manufacture.—In this country, and in the north of Europe generally, hard-soap is made from tallow, palm oil, bone grease, and kitchen fat, by boiling to saturation with caustic-soda. Cocoa, palm nut, and some other oils are occasionally used, chiefly in imitating superior soaps, and the only other ingredient of consequence is rosin, the residuum of the distillation of rough turpentine. In the south of Europe, coarse olive-oil is the staple material, and from this is produced the marbled soap known as 'Marseilles.'

The soap-maker first dissolves in boiling water 6 to 8 cwt. of crude soda-ash (see SODA) in a cast-iron circular vessel (contents may be 1000 gallons), furnished with a steam-pipe in its center. He then adds half the weight of *pure caustic* lime, and boils the mixture. When the lime has rendered the soda caustic, the boiling is discontinued, subsidence takes place, and the lye is ready for use.

Soap-pans are of various sizes. One of moderate dimensions may turn out from six to eight tons, and is usually formed of four pieces of cast-iron—lower casting, say five feet in diameter; upper, eleven. Heat is applied either by means of a furnace beneath the bottom piece, or by open steam introduced by a pipe led to a circular perrorated ring at the bottom of the pan. Steam-boiling being now extensively adopted, our description will apply to that method.

Curd or White Soap.—20 cwt. of tallow being put into the soap-pan, and a quantity of the prepared lye, steam is turned on, and boiling continued until the lye is thoroughly incorporated with the tallow, and becomes a pasty mass. A few shovelfuls of common salt are now thrown in when the lye begins to separate. The partially formed soap is allowed to cool, and the salted lye, now deprived of its soda, subsides, and is drawn off from the bottom by a pipe, or removed by a pump. The operation of adding and boiling with lye is repeated until the tallow is saturated with soda, and the lyes show as much alkali after boiling as before. The soap is now treated with weaker lye, and by more or less water brought to the consistency the maker requires. From its tendency to thicken rapidly, it is transferred to the frame at a higher temperature than the soap next described.

Pale or Yellow Soap.—When the tallow is saponified as above described, about ⅛d of its weight of rosin is added, and the boilings with lye repeated, until the mass is thoroughly saponified. The practised workman being aware that perfect soap is insoluble in strong alkali, avoids the risk of imperfect particles escaping the action of the lye from being enveloped in perfect soap, by reducing the mass with water, and adding lye gradually until the soap again floats as a curd on the liquid. The soap is then cooled down, and the lye being removed as completely as possible, it is boiled with the quantity of water necessary to bring it to the consistency required. These later operations require much experience, and the best theoretical knowledge requires the aid of tongue and eye to carry them through with success. The soap being now *finished* (the technical term), the copper is covered up, and the contents allowed to settle until the temperature falls to about 160° Fahrenheit. According to the quantity of water used, so is the deposit, called the *nigre*, greater or less. When too much water is used, the produce of soap is too small; when too little, the produce is large, but of inferior quality, from the insufficient deposit of impurities. This nigre is employed in making second-class soap. When of proper temperature, the soap is removed into frames, now mostly made of cast-iron, containing about 10½ cwt. each, where, after solidifying, which it does in three days, it is cut by wire into slabs, which are again cut transversely into bars ready for the market.

London Mottled is made of kitchen fat (no rosin). The process described in the making of curd soap is followed here, except that

when perfect the soap is, when almost boiling, put into wooden frames three or four times as high as the ordinary frame of 52 inches, and the lye allowed to percolate through the soap to the lower part of the frame, producing the mottled appearance desired. As this soap, when subjected to any mixing operation, lost its *mottle*, it long enjoyed a high reputation as a genuine soap; but now that cheap imitations, having a beautifully marbled appearance, are produced from cocoa and palm nut oils, with coloring and silicious matter, its prestige is somewhat on the wane.

The numerous patents taken out for improvements in soap-making have had for the most part more the object of cheapening, by the addition of various articles to soap in its semi-fluid state, than of improving the manufacture.

Soft-soap differs from hard from having potash for its base instead of soda. The repeated changes of lye described in the manufacture of hard-soap are here inadmissible, for all the lye employed remains in combination with the oily materials, and is never separated. Hence open steam, as throwing in water into the mass, cannot be applied, nor can salt, so useful an agent in the former manufacture, be used, as it would tend to separate the soap from the lye, while a thorough combination is essential. The making of soft-soap requires much experience and nicety, it being so easy to overdo the supply of alkali, which cannot happen in hard-soap. A ton of materials, consisting of 1900 lbs. of fish or other oil, with 340 lbs. tallow, is put into the soap-pan with 200 gallons of American potash lye of such strength that 6600 grains of real potash are in each. After being boiled by the heat of a furnace, and well beat down on the surface to keep in bounds the frothy mass, a stronger lye, containing about 8700 grains of potash per gallon, is added at short intervals, and the boiling carried on until the workman ascertains by taste and appearance that the soap is perfect. The tallow serves to give consistency to the soap, and also produces white specks of stearate of potash, which much enhance its appearance.

SOAP, MEDICAL USES OF. The only kind of soap that should be used internally is *White Soda Soap*. It is prepared from caustic soda, and either olive or almond oil. In its purest state, it is called *Medicinal Soap*, while in its less pure forms it is known as Alicant, Venice, or Spanish Soap. When properly made, it should be perfectly soluble in pure water and in alcohol. It is chiefly employed to form pills of a gently aperient and antacid action. Pills containing a combination of soap and dried carbonate of soda, are of great use in certain forms of gravel. Soap is often added to pills as an adjuvant, or for the purpose of preventing them from becoming hard and insoluble. White soap affords a ready antidote in cases of poisoning with the strong mineral acids. *Soft-soap* ought to be made with olive oil and potash, and it should be of yellowish-white color, inodorous, and of the consistence of thick honey. It is of great service, as an external application, either alone or in association with sulphuret of potash, and other remedies, in various cutaneous affections.

SOAPBERRY (*Sapindus saponaria*, a West Indian tree, of the natural order *Sapindaceæ*, the pulp of the fruit of which is used instead of soap in washing. This property belongs to other species of the same genus. With the exception of *S. marginatus*, found in the southern states of North America, the genus is entirely tropical. The use of the pulp as soap, if often repeated, is apt to injure linen; but it is capable of cleansing as much linen as sixty times its weight of soap. Each fruit contains a nut of a shining black color. These nuts are very hard, and were formerly imported into Europe to be made into waistcoat buttons, being tipped with silver or other metal. They were little liable either to be injured by wearing or to be broken.

SOAP-STONE. See STEATITE.

SOAP-TEST. This test, for which science is indebted to Professor Clark of Aberdeen, is now universally employed for determining the degree of hardness of water. Every one knows how much more readily a lather is formed—as, for example, in washing the hands—with soft than with hard water. This is accounted for by the earthy bases of the hard water displacing the alkaline bases of the soap, and forming compounds insoluble in water. This is the foundation of the soap-test. A hard water of known strength is first prepared by dissolving 16 grains of pure carbonate of lime in pure hydrochloric acid, evaporating to dryness, and dissolving the resulting chloride of calcium in a gallon of distilled water. This gallon of chloride of calcium solution accurately represents a natural water whose hardness is due to 16 grains of carbonate of lime in a gallon. A solution of soap in proof-spirit is next prepared of such strength, as that a quantity of it which will fill 32 measures of a volumetric tube, each measure of which contains 10 grains, will be exactly able to convert 1000 grains' measure of the standard solution of hard water into the earthy soap described. This point is thus ascertained: The hard water is placed in a stoppered bottle, and the soap solution added to it by degrees, the bottle being shaken after each addition when a bubble will form, which rapidly disappears so long as any lime is present; but when at last it is all used up, a froth of soap bubbles remains after hard shaking, such as to last unbroken for three minutes. If, now, a given sample of water be examined, and this point is reached at the expense of the entire 32 measures, it is a water of 16 degrees of hardness. Now, perfectly soft water consumes 2 measures of the soap solution before permanent bubbles are formed, so that a water of 16 degrees of hardness has in reality only consumed 30 measures of the soap solution. But $\frac{16}{30} = 0{\cdot}53$; hence, if any given measures of the soap-test be used in estimating the hardness of a water, we must first subtract 2 from the amount, and then multiply by 0·53; and the result will give us the degree of hardness. For example, let a given sample require 27 measures of the soap-test. On subtracting 2, and multiplying by 0·53, we find its hardness to be 12·25.

Clark's Soap-test Table for Hardness of Water is given in the article 'Soap-test' in Knight's *English Cyclopædia;* and full details regarding the mode of working the test, to determine the amount of lime, magnesia, soda, sulphuric acid, and pure carbonic acid, are given in Dr. Parkes's *Manual of Practical Hygiene* (Lond. 1864).

SOAPWORT (*Saponaria*), a genus of plants of the natural order *Caryophyllaceæ*, having a cylindrical or ventricose,5-toothed calyx, without any outer calyx or attendant bracteæ, five undivided petals with long claws, ten stamens, two stigmas, and a capsule opening at the top by four valves. Some of the species have very beautiful flowers. *S. Calabrica* has of late become one of

Soapwort (*Saponaria officinalis*).

the most favorite annuals of our flower-gardens.—COMMON S. (*S. officinalis*) is found on waysides, in thickets, and on the banks of streams, in most parts of Europe, although it is a somewhat doubtful native of Britain. Both the root and the leaves contain Saponin (q. v.), in consequence of which they are sometimes employed for washing. The brownish-red color of the bark of the root, however, is apt to tinge white articles. The root of this plant has also medicinal properties, being aperient, resolvent, and alterative. It is sometimes sold as RED SOAPROOT.

Nearly allied to the genus *Saponaria*, but having an angular calyx and a 5-valved capsule, is the genus *Gypsophila*, some species of which are called SOAP-ROOT, and contain much saponin. Thus, the EGYPTIAN SOAP-ROOT (*G. struthium*), and the SPANISH SOAP-ROOT (*G. Hispanica*), called *Jabonera* in Spain, have been employed for washing from time immemorial, and the roots not having a dark rind, can be used for washing white articles, and are to some extent an article of commerce, being used for silken and other stuffs, the colors of which will not bear the application of soap. The roots of *Lychnis dioica*, one of the most common British plants, possess the same properties in an inferior degree.—The bark of *Quillaja saponaria*, a Chilian tree of the natural order *Rosaceæ*, contains much saponin, is generally used for washing in Chili and Peru, and there forms a considerable article of commerce.—Some of the tropical South Sea Islands produce a species of vine (*Vitis saponaria*), the stem of which, especially the thicker part, cut into pieces, and softened by cooking on hot stones, produces in water a rich lather almost equal to that of soap. See also SOLANUM.

SOBBING is merely a modification of the ordinary movements of respiration excited by mental emotions. It is the consequence of a series of short convulsive contractions of the diaphragm, and is usually accompanied by a closure of the glottis, preventing the entrance of air into the lungs.

SOBIESKI, JOHN. See JOHN III.

SOBRAO'N, a village on the left bank of the Sutlej, 25 miles east-north-east of Ferozpur, near which, on 10th February 1846, a most obstinate battle was fought between the British army of

15,000 men, under Sir Hugh Gough, and a Sikh force numbering 30,000. The Sikhs were strongly entrenched, and vigorously resisted the attacks of their opponents, but the courage and perseverance of the latter ultimately gave them the mastery; the various earthworks were captured in succession, and the Sikhs driven across the Sutlej, with a loss in killed, wounded, and drowned of 13,000. Gough immediately followed up his victory by crossing into the Punjab in pursuit of the fleeing enemy.

SOCAGE, or SOCCAGE (originally *hlaford-socn*, seeking a lord; whence we have also *soc*, a right of holding a court), a tenure of lands in England, of which the characteristic feature is, that the service is fixed and determinate in quality, thereby differing both from knight-service and from villeinage. It was originally peculiar to the Anglo-Danish districts of England. At the time when the allodial tenure was converted into immediate dependence on the crown, this tenure seems to have arisen out of the necessity for commendation or seeking a lord. In Domesday, socmen are often mentioned as bound 'to seek a lord,' or free to go with their land where they pleased. The socmen of Stamford are said to be free to seek a lord, being only liable to the king for the toll attached to them as inhabitants of a borough. The obligation of socage in its origin has been compared to the mutual bonds of allegiance of later times so common in the Highlands of Scotland, and known as Bonds of Manrent (see MANRENT). Three kinds of socage have been enumerated as existing at a later period—viz., free and common socage, socage in ancient tenure, and socage in base tenure. The second and third kind are equivalent to tenure in ancient demesne and copyhold tenure (see DEMESNE, ANCIENT, and COPYHOLD), and the first is what has generally and more properly been denominated socage, where the services were both certain and honorable. Besides fealty, which the socager was bound to do when required, he was obliged to give attendance at the court baron of his lord, if he held one, either for a manor or for a seigniory in gross.

By an act passed during the Commonwealth, and confirmed after the Restoration by 12 Car. II. c. 24, tenure by knight-service was abolished, and all lands except church-lands held in free-alms, were directed to be held in free and common socage, which is now (with that exception) the universal tenure of real property in England and Ireland.

Socage tenures are unknown in Scotland, where, unless at a very early period, they never existed.

SOCIALISM, the name given to a class of opinions opposed to the present organization of society, and which seeks to introduce a new distribution of property and labor, in which organized *co-operation* rather than *competition* should be the dominating principle, under the conviction that the happiness of the race, and especially of the classes without capital, would be benefited thereby. Historically considered, Socialism, like many of the significant phenomena of our age, is a product of the French Revolution. That terrible outburst of popular discontent is most properly regarded as an anarchic attack on the social system that had its roots in the feudalism of the middle ages. The furious hatred of the court and the aristocracy, the passionate love of the 'people,' of 'humanity,' of 'liberty,' though called forth by special circumstances, and never formally worked out into a theory of social life, virtually contained in themselves the germs of all later proposed organizations. In the middle ages, the *right* of freely and fully enjoying life, property, and political independence was limited to a favored few; while the great masses were condemned to dumb servitude, and a perpetual minority. Even the industrial population did not recognize the Socialistic idea. The members of the different guilds or fraternities claimed exclusive right to exercise certain branches of industry, and probably the great majority of the inhabitants of a town remained in a disregarded and dependent state. Amid such social conditions, resting, as they did, on a belief in the necessity of different distinct ranks, the free action of individual life, and even the vital progress of the whole community, became well-nigh impossible.

We have not space here to trace the course of the various minor reforms that weakened the authority of the medieval theory of life; but we must not omit to notice the speculations of the political philosophers of the 18th c. in France, England, and Germany, as operating powerfully in favor of a new social system, in which the idea of humanity (assuming, at the French Revolution, as we have observed, the concrete form of the 'people') stands out prominently. Nevertheless, the first shape that the modern spirit of industry took, was not Socialistic, in the strict and proper sense of the term: it was rather individualistic, and found, as it still finds—for it is yet the prevailing theory—its natural expression in such proverbs as, 'A fair field, and no favor;' 'Everyone for himself, and God for us all.' But still, even this lawless individualism is to be regarded as a protest against the false *class*-legislation of preceding times, and as an assertion of the absolute right of *each member of society* to a share in the general welfare. That it has not universally commended itself to civilized mankind, as a perfect system, is demonstrated by the appearance and temporary popularity of such schemes of society as those of Owen (q. v.), Fourier (q. v.), St. Simon (q. v.), and the enthusiasm excited at intervals in different parts of Europe by the promulgation of extreme communistic opinions. See COMMUNISM. It is objected to Socialism, under its various forms, that it makes human happiness too much dependent on material gratifications; that it robs man of that energy that springs from ambition; that it unphilosophically ignores an individualism and inequality to which Nature herself has given her inviolable sanction; and that, by the abolition of social rewards and punishments, it neither holds out any hope to the industrious, nor excites any apprehension among the indolent. On the other hand, we must admit that the vigorous assertion of Socialistic principles has led men to a more liberal and generous view of humanity as a whole. Moreover, it has forcibly called public attention to numerous evils that have sprung up along with the modern development of industry, for which no remedy—not even a name—had been provided; to the vital interdependence of all classes; and to the inadequacy of the individual or 'selfish' system, as it has been called, to redress the wrongs or cure the evils that inevitably spring from its own unchecked operation. The recent spread of Socialistic opinions in Germany, taken in connection with the two attempts made on the life of the emperor, has led, in 1878, to special and stringent legislation designed to check the growth of Socialism. In 1878 it was computed that there were in Germany 75 Socialistic publications, with 135,000 regular subscribers.

SOCIAL SCIENCE, a name that has of late years been given to the study of all that relates to the social improvement of the community. A society, called 'The National Association for the Promotion of Social Science,' was first organized at a meeting which was held under Lord Brougham's auspices in July 1857, to consider the best means of uniting together all those interested in social improvement. The annual meetings have been held each year at a different place. The Association as now constituted comprises five sections—1. Jurisprudence and Amendment of the Law (subjection, Repression of Crime); 2. Education; 3. Health; 4. Economy and Trade; 5. Art. The Association aims at promoting improvement in all matters falling within these departments, by means of bringing together, for free discussion, societies and individuals interested in social problems.

SOCIOLOGY is the somewhat barbarous name that has of late been used to denote the study of the origin, organization, and development of human society.

SOCIETIES are associations of individuals for the promotion or accomplishment of some particular object. Such objects are numerous, including the promotion and investigation of almost every well recognized branch of science, art, and literature; the diffusion of knowledge, religion, and morality; intercourse between those of the same profession or trade; the removal of legal grievances; mutual aid in case of distress; and an abundance of other aims, which are either beneficial to the general public, or to the members of the society alone. In Great Britain, any number of persons may agree to constitute themselves a society, if the object of their union is legal. Those whose objects are scientific or literary are occasionally called *Academies* (q. v.), and under this or their own special names will be found notices of the chief societies at present existing. 'Secret' societies for the accomplishment of some object which involves a subversion of existing political arrangements, spring up from time to time in France, Ireland, Italy, &c.

SOCIETY ISLANDS, a small archipelago in the South Pacific Ocean, in lat. 16°—18° S., long. 148°—155° W., is formed of a number of islands, which are now all actually or practically French possessions. There are 13 main islands—Tahiti or Otaheite, Maitia, Eimeo, Maiaoiti, Tetuaroa, Otaha, Moorea, Tuba, Lord Howe's Island, Scilly Island, Huahine, Raiatea, and Borabora. Area 650 sq. m.; pop. 18,000. The capital of Tahiti is Papiete (pop. 2000). The chief agricultural enterprise in Tahiti is an estate of 10,000 acres in the hands of an English company. The islands closely resemble each other in appearance. They are mountainous in the interior, with tracts of low-lying and extraordinarily fertile land occupying the shores all round from the base of the mountains to the sea. They are surrounded by coral reefs, are abundantly watered by streams, and enjoy a temperate and agreeable climate. Almost every tropical vegetable and fruit known is grown here; but agriculture is in a backward state. The animals are those usually found in the South Sea Islands. The inhabitants belong to the Malay race, are affable, ingenious, and hospitable, but volatile and sensual. The practice of tattooing has almost wholly disappeared, and the native costume now closely resembles that of civilized nations. There are now no native manufactures, these having been entirely superseded by imported goods. Cocoa-nut oil, oranges, lime-juice, kauri shells and pearl shells are the principal articles exported; and cocoanuts are the general article of barter throughout the islands for calicoes, cotton cloth, knives, cordage, groceries, &c., which are imported chiefly from Tahiti. The exports from Tahiti, the principal island, amounted in 1875 to £105,000, and the imports to £120,000.

Tahiti is said to have been visited as early as 1606. Captain Cook reached it in 1769, and discovered many of the other islands of the archipelago, to which he gave the name of S. I., in honor of the Royal Society of London. In 1797, the first mission-ship fitted out by the newly formed London Missionary Society arrived at Tahiti. After 19 years of apparently fruitless labor, the influence of the missionaries began to be felt, and soon afterwards became so powerful as to be almost paramount. A quarrel between the Protestant and the Roman Catholic missionaries, who thought it better to enter upon ground already occupied by Protestants than to take up new ground for themselves, occasioned the interference of France in favor of the latter, and the island of Tahiti was taken possession of in the name of Louis Philippe, by a strong French force in 1844. All the possessions of the native ruler were afterwards placed under the protection of France; and by a treaty concluded in 1880, Tahiti and its dependencies (particularly Moorea, Tetuaroa, and Raiatea), became French possessions. Many of the Protestant missionaries left the island in consequence of the interference of the French authorities with their labors. Some, however, remained, and the congregations continued to meet. An application to the British government procured a concession on the part of the French government of some of the rights of religious liberty, which had been taken away by the local authorities.

SOCINUS, the name of two celebrated heresiarchs, uncle and nephew, who have given name to a sect of Christians, the Socinians, better known, however, as Unitarians (q. v.).—**Lælius Socinus**, the elder of the two, was born at Siena, in Tuscany, in 1525, and belonged to a family that had long been distinguished for its cultivation of literature and science. His father, Marianus Socinus, was an able lawyer, and designed his son for the same profession. But Lælius soon displayed a strong preference for theological inquiry, and in order to better prosecute his biblical studies, he made himself familiar with Greek, Hebrew, and Arabic. The only result of his legal training that one can discern is an obstinate aversion to believe anything 'unreasonable.' The principles of the Reformation had slowly found their way into Italy, and in 1546, a secret society was formed at Vicenza for the discussion of religious questions. It was composed of 40 persons, distinguished by their rank, their occupations, and their titles. S. was admitted a member. The conclusions at which they arrived were unfavorable to the dogma of the Trinity, which they held to have been borrowed by the early church from the speculations of Greek philosophers. The purpose of their meetings together having been discovered, the society broke up. Some of the members were arrested and put to death, others sought safety in flight. Among the latter was S., who traveled in France, England, Holland, Germany, and Poland, making the acquaintance, and acquiring the esteem, of many transalpine scholars, and finally settled in Zürich, where he died in 1562, when only 37 years of age. Lælius S., unlike most heretics, was a prudent and reticent man. His speech at least never bewrayed him; but in his correspondence with his Italian relatives and friends, he showed himself an ardent and eloquent disputant, and made not a few proselytes. Once, in a moment of mistaken confidence, he disclosed himself to Calvin, who grimly warned him to get rid of his 'itch of inquiry,' lest he should 'draw on himself great torments.' In the same year occurred the murder of Servetus.—See Illgen's *Vita Lælii Socini* (Leip. 1814), and *Symbolæ ad Vitam et Doctrinam Lælii Socini* (Leip. 1826).

Socinus, Faustus, nephew of the preceding, was the son of Alessandro Socinus, and was also born at Siena, 5th December, 1539. By the mother's side, he was very highly connected; but having lost his parents while still young, his education was carelessly conducted; and he himself, at a later period, lamented the imperfection of his scholastic culture. His want of learning, however, only induced him to speculate the more freely, and thus it happened, partly from native bias, and partly from his uncle's epistolary arguments, that Faustus was a heretic and anti-Trinitarian before he was out of his teens. In 1559, when only 20 years of age, he found it advisable to seek an asylum in France, and was living at Lyon when he got news of his uncle's death. He immediately proceeded to Zürich, and possessed himself of his relative's MSS., after which he returned to Italy. He entered the service of the Grand Duke of Tuscany, and during twelve years seemed to forget, amid the cares of office and the dissipations of a court, the thorny questions of theology. But at the ex-

piry of that period, he was seized with a stronger desire than ever to investigate the truths of religion, and in spite of all remonstrances, proceeded to Germany—the center of theological activity. In 1574, he retired to Basel, to prosecute his studies more closely; but a disputation which he had with a certain Fr. Pucci (1578), obliged him to leave Switzerland. At the request of George Blandrata, he visited Transylvania, where anti-Trinitarians were numerous, especially among the nobles, and eagerly sought (not without success) to make converts to his opinions. In 1579 he went to Poland. Anti-Trinitarianism was even stronger there than in Transylvania, and S. soon obtained a great influence. He preached, and disputed, and wrote with a zeal that Socinianism has seldom displayed since. His position in relation to the Reformers was, that Luther and Calvin had rendered great services to the cause of religion, but that they had not gone far enough, that the only solid basis on which Protestantism could rest was human 'reason,' that everything that contradicted it should be rejected as false and incredible, and that dogmas that were absurd should not be allowed to shelter themselves from criticism because their defenders chose to call them 'mysteries.' The Protestants were alarmed, and the ablest among them undertook publicly to confute Socinus.

A disputation was held in the college of Posna, which ended in S. reducing all his opponents to silence; but they retaliated (after the unscrupulous fashion of the times) by trumping up against their vanquisher a charge of sedition, which, although ridiculously groundless, made it necessary for S. to withdraw from Cracow. While living in retirement on the estate of a Polish noble, Christopher Morsztyn, he married the daughter of his protector. She seems to have been a tender and affectionate wife; and when S. lost her in 1587, he almost broke his heart through grief. About this period, his property in Italy was confiscated; but he had powerful and wealthy friends in Poland, who proved generous to him in his needs. In 1588, he took part in the synod of Brest (on the borders of Lithuania), and combated all the principal dogmas of the church—the divinity of Christ, propitiatory sacrifice, original sin, human depravity, the servitude of the will, and justification by faith. In 1598, on the publication of his *De Jesu Christo Servatore*, his enemies stirred up the populace of Cracow against him; and S. was pulled from a sick-bed, and nearly murdered. Soon after he left the city, and found a refuge with one of his friends in the village of Luclavie, where he died, 3d March 1604. S.'s works are no longer read; but his opinions have never wanted advocates in any Protestant country. He and his uncle may be regarded as precursors of that spirit of Rationalism which has rooted itself so deeply in the thought of the modern world.—See Przipcow's Life of S., prefixed to a collection of his works in the *Bib. Frat. Polonorum* (Amst. 1656); Bayle's article in the *Dictionnaire;* and Toulmin's *Memoirs of the Life, Character, &c. of F. S.* (Lond. 1777).

SOCOTRA, an island near the entrance to the Gulf of Aden, 80 miles long and 30 broad. Area over 1000 square miles; pop. 5000. It was partly explored under the auspices of the British Association in 1879, and new information obtained as to its fauna and flora. The surface consists for the most part of a table-land of from 700 to 800 feet high, and low plains skirt the northern and southern shores. All the streams of the island, with the exception of a few rivulets, are dry at a certain season; but rain water is collected in reservoirs, and in most parts water can be obtained by digging a few feet below the surface. Owing to the somewhat unfertile character of the soil, most of the districts are more adapted for pasture than for agriculture; but grain, fruits, and vegetables are grown in the eastern districts. The aloe plant and the dragon's-blood tree are the chief commercial products. S. belongs to the sultan of Keshin, who, in 1876, concluded a treaty, by which, in respect of S., he becomes a feudatory of Great Britain.

SOCRATES, the celebrated Greek philosopher, was born at Athens in the year 469 B.C. His father, Sophroniskos, was a sculptor; and he followed the same profession in the early part of his life. His mother, Phænarete, was a midwife, to which avocation he was wont to compare his own peculiar method of conversational teaching. His family was respectable in descent, but humble in point of means. His physical constitution was robust to an extraordinary degree, enabling him to endure the hardest military service, and to live his own chosen life of superiority to all wants above the barest necessaries of life. While his ordinary diet was simple and abstemious, he could, on religious festivals or social occasions, drink more wine than any one else without being intoxicated. He had the usual education of an Athenian citizen, which included not only a knowledge of the mother-tongue, and readings in the Greek poets, but also the elements of arithmetic, geometry, and astronomy as then known. As a young man, he frequented the society of the physical philosopher, Archelaus, (a disciple of Anaxagoras); but the philosophers that did most to determine his own special turn of mind must have been Parmenides and 'the double-tongued and all-objecting Zeno.'

Excepting in connection with his philosophical career, few circumstances of his life are known. He served as a hoplite, or heavy-armed foot-soldier, at the siege of Potidæa, at the battle of Delium, and at Amphipolis, and his bravery and endurance were greatly extolled by his friends. On two memorable occasions, he stood forward in political life. After the battle of Arginusæ, in 406, the ten generals in command were publicly arraigned for neglecting to obtain the bodies of the killed to receive the rites of interment. The clamor for their condemnation was so great, that the court wished to proceed in violation of the legal forms; but S., as the presiding judge, firmly refused to put the question. The other occasion was during the tyranny of the Thirty, who took up the policy of compelling a number of influential citizens to take a part in their illegal murders and confiscations; but S. withstood them at the peril of his own life.

Somewhere about the middle period of his life, he relinquished his profession as a statuary, and gave himself up to the career that made him famous. Deservedly styled a philosopher, he neither secluded himself for study, nor opened a school for the regular instruction of pupils. He disclaimed the appellation of teacher; his practice was to talk or converse, 'to prattle without end,' as his enemies said. 'Early in the morning, he frequented the public walks, the gymnasia for bodily training, and the schools where youths were receiving instruction; he was to be seen in the market-place at the hour when it was most crowded, among the booths and tables where goods were exposed for sale. His whole day was usually spent in this public manner. He talked with any one, young or old, rich or poor, that sought to address him, and in the hearing of all who chose to stand by. He visited all persons of interest in the city, male or female; his friendship with Aspasia is well known; and one of the most interesting chapters of Xenophon's *Memorabilia* recounts his visit to and dialogue with Theodotê—a beautiful *hetæra*, or female companion. Nothing could be more public, perpetual, and indiscriminate as to persons than his conversation; and as it was engaging, curious, and instructive to hear, certain persons made it their habit to attend him in public as companions and listeners. These men, a fluctuating body, were commonly known as his disciples or scholars, though neither he nor his personal friends ever employed the terms *teacher* and *disciple* to describe the relation between them.'—Grote's *Greece*, chap. lxviii.

Another peculiarity of S. was his persuasion of a special religious mission. He had been accustomed all his life to hear what he considered a divine voice, or preternatural sign, which came to him solely as a prohibition or warning, and never as an instigation to act. In deference to it, he had kept back from entering public life, and it caused him to refrain from premeditating the defence that he made on his trial. Nor was this all; relying, like his countrymen, on divine intimations by dreams and oracles, he believed that his mission had been signified to him by these. One oracular intimation in particular he described in his defence as the turning-point of his life. An admirer and friend of his, Chærephon, about the time when he began to have some repute as a wise man, consulted the oracle at Delphi as to whether any man was wiser than Socrates. The priestess replied: 'None.' The answer, he said, perplexed him very much; for he was conscious to himself that he possessed no wisdom on any subject, great or small. At length, he resolved to put the matter to the test by taking measure of the wisdom of other persons as compared with his own. Selecting a leading politician, accounted wise by himself and by others, he put a series of questions to him, and found his supposed wisdom was no wisdom at all. He next tried to demonstrate to the politician himself how much he was deficient; but found him impracticable on this head, refusing to be convinced. He then saw a meaning in the oracle to the effect that his superiority to others lay not in his wisdom, but in his being fully conscious of his ignorance. He tried the same experiment on other politicians and rhetors, then on poets, and lastly on artists and artisans, and with the same result. Thereupon, he considered it as a duty imposed upon him by the Delphian god to cross-question men of all degrees as to their knowledge, to make them conscious of their ignorance, and thereby put them in the way of becoming wise. We shall see presently wherein this low view of the human intelligence differed from the contemptuous tone of a mere satirist.

The intellectual characteristics of S., through which he influenced the whole subsequent course of human thought, may be stated under three heads: 1. Subject, 2. Method, and 3. Doctrine.

1. As to Subject.—Here he effected a signal revolution, metaphorically expressed by the saying of Cicero, that 'Socrates brought down philosophy from the heavens to the earth.' The previous philosophies consisted of vast and vague speculations on nature as a whole, blending together Cosmogony, Astronomy, Geometry, Physics, Metaphysics, &c. S. had studied these systems, and they left on his mind a feeling of emptiness and un-

suitability for any human purpose. It seemed to him that men's endeavors after knowledge would be better directed to the human relationships, as involving men's practical concerns. He could not go to any public assemblage without hearing questions agitated respecting the just and unjust, the honorable and base, the expedient and hurtful; moreover, he found that the opposing disputants were, without knowing it, very confused in their ideas as to the meanings of those large words in which the weightiest interests centered. Accordingly, he was the first to proclaim that 'the proper study of mankind is man;' human nature, human duties, and human happiness made up a field of really urgent and profitable inquiry. In astronomy, he saw a certain utility for navigation, and for the reckoning of time, to which extent he would have it known by pilots and watchmen; geometry was useful in its literal sense of land-measuring; arithmetic he allowed in like manner so far as practically useful; but general physics, or the speculations of philosophers, from Thales downward, as to the origin of all things out of water, fire, air, &c., he wholly repudiated. 'Do these inquirers,' he asked, 'think that they already know *human* affairs well enough, that they thus begin to meddle with divine? Do they think that they shall be able to excite or calm the winds at pleasure, or have they no other view than to gratify an idle curiosity?' He considered it not only unprofitable but impious to attempt to comprehend that department. The gods, he thought, managed all those things after their own fashion, and refused to submit them to invariable laws of sequence, such as men might discover by dint of study; the only means of knowledge permitted was religious sacrifice and prayer, and the consultation of the oracles. While this was the appointed way in reference to divine things, it was equally appointed that human things should be learned by diligence in study and investigation.

2. In regard to Method, S. was the author of still greater innovations. It was to little purpose that men applied themselves to human affairs, if they conceived them loosely, and with no regard to evidence. S. introduced at least one element of logical precision into the handling of questions, by insisting on accuracy in Definition and Classification. His mode will be seen in the statement of Xenophon. 'Socrates continued incessantly discussing *human* affairs, investigating—What is piety? What is impiety? What is the honorable and the base? What is the just and the unjust? Men that knew these matters, he accounted good and honorable; men that were ignorant of them, he assimilated to slaves.'

His investigation thus took the form of ascertaining the exact meaning—that is, the definition—of the leading terms in ethics and in politics, the settling of what J. S. Mill calls the *connotation* of a general word, which determines how to apply it rightly to each individual case. The very idea of defining a general term, now so obvious, never seems to have suggested itself to any one previous to Socrates. And his manner of seeking out those definitions is also characteristic, and links itself to his conversational method, and his convicting men in general of ignorance in things that they thought they knew. Professing himself to be able to furnish no exact definition (this professed ignorance was called the Socratic irony) of justice, temperance, courage, &c., and finding every one else quite confident in their ability to supply the want, he asked some one to state his definition; and on its being given, he put a few further interrogations (as he said) by way of making sure that he understood the meaning, but with the speedy effect of driving the respondent into a humiliating self-contradiction. His method is most fully exemplified in certain of the Platonic dialogues, as the first *Alcibiadês*, *Lachês*, *Charmidês*, *Euthyphron*, &c.

According to Xenophon, he could pass from his severe cross-examining method, with its humiliating shock of convicted ignorance, and address to his hearers plain and homely precepts, inculcating self-control, temperance, piety, duty to parents, brotherly love, fidelity in friendship, diligence, &c.—such direct admonitory influence being common to him with the so-called Sophists. He probably went beyond the ordinary teaching of the Sophists in exhorting men 'to limit their external wants, to be sparing in indulgence, and to cultivate, even in preference to honors and advancement, the pleasures arising from a performance of duty, as well as from self-examination and the consciousness of internal improvement.' This strain of exhortation, his manner of life in harmony therewith, and the virtual self-immolation of his death, may be considered as the conjoint root of the Cynic and the Stoic philosophies.

3. As regards Doctrine, S. was distinguished chiefly by his theory of virtue. Virtue, he said, consisted in knowledge. To do right, was the only road to happiness; and as every man sought to be happy, vice could arise only from ignorance or mistake as to the means; hence the proper corrective was an enlarged teaching of the consequences of actions.

We cannot, on any fair interpretation of knowledge, regard this as other than a one-sided view. It takes note of one condition of virtue, since there can be no right conduct without understanding the tendency of actions, or, at all events, the meaning of rules; but it omits, what is also essential, the state of the emotions or dispositions, which may be directed either to exclusively self-regarding ends, or to ends involving also the good of others. There is an obvious connection between the doctrine and the Socratic analogy of virtue to the professions. The virtue of an artisan is almost exclusively contained in his skill or knowledge; his dispositions can usually, though not always, be depended on, through the pressure of his immediate self-interest. But the practice of S. was larger than his theory; for, as already remarked, his exhortations were addressed to men's feelings or sentiments as well as to their intellect. His political doctrines were biased by the same analogy of special professions. The legitimate king or governor was he alone that knew how to govern well.

In the year 399 B.C., an indictment was laid against S., in the following terms: 'Socrates is guilty of crime: first, for not worshiping the gods whom the city worships, and for introducing new divinities of his own; next, for corrupting the youth. The penalty due is death.' The trial took place before a dikastery, or law-court, composed of citizen-judges, like our juries, but far more numerous; the number present seems to have been 557. His defence is preserved by Plato, under the title *Apology of Socrates*. The tone of it, so admirable to us, was such as to make acquittal all but impossible, from the number of enemies created by his cross-questioning annoyance of all classes of men, and from various other causes. He dwelt on his mission to convict men of ignorance for their ultimate benefit; pronounced himself a public blessing to the Athenians; declared that, if his life was preserved, he would continue in the same course; and regarded the prospect of death with utter indifference. By a majority of either five or six, the charges were declared to be proven. A vote had then to be taken on the sentence. By the Athenian practice, the accuser named a penalty, and the accused was asked to do the same; the judges were restricted to one or other of these. The accuser named death. S., maintaining the same high tone, declared at first that he deserved the highest public reward; but, on the instigation of his friends, he ended by proposing a trifling fine. The court, by a majority, decided for the capital sentence. There was an accidental interval of 30 days before the execution, during which S. in prison conversed with his friends as usual; on the last day occurred his conversation on the Immortality of the Soul, referred to in the Platonic dialogue called *Phædon*. He then drank the hemlock, and passed away with the dignity and calmness becoming his past life.

'There can be no doubt,' says Mr. Grote, 'that the individual influence of Socrates permanently enlarged the horizon, improved the method, and multiplied the ascendant minds of the Grecian speculative world, in a manner never since paralleled. Subsequent philosophers may have had a more elaborate doctrine, and a larger number of disciples who imbibed their ideas; but none of them applied the same stimulating method with the same efficacy; none of them struck out of other minds that fire which sets light to original thought; none of them either produced in others the pains of intellectual pregnancy, or extracted from others the fresh and unborrowed offspring of a really parturient mind.'—See Grote's *Greece;* Zeller's *Philos. der Griechen*.

SODA. See SODIUM.

SODA, MANUFACTURE OF. Soda, or more correctly, carbonate of soda, occupies the chief place among our leading chemical manufactures, alike from its own importance, and also on account of its influence on other great chemical industries, such as glass-making, soap-making, bleaching, &c.

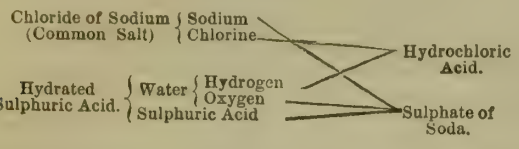
A native carbonate of soda, or rather a sesqui-carbonate, called Natron (q. v.), is found in Egypt and some other parts of the world. In Hungary several manufactories exist for the purification of a native soda found there. Formerly, most of the soda in use was extracted from certain plants; and two kinds were known in commerce under the names of Barilla (q. v.) and Kelp (q. v.).

But the quantity of soda got from all other sources is now insignificant in comparison with that manufactured from common salt (chloride of sodium—see SODIUM). The process was invented by a Frenchman named Leblanc, and was first made known to the world by a commission of the French republic in 1794, although dating some years earlier. It is unquestionably the most valuable discovery in the entire range of chemical manufactures; and it has been practised for nearly ninety years without any important alteration. It is sad to think that the author of this invention reaped no benefit from it himself, but spent the last of his days in an hospital, 'a wreck in fortune, health, and hope.' Owing partly to the war between France and England, and partly also to the existence of a duty of £30 per ton on common salt, which continued for eight years after the close of the war, Leblanc's process was not adopted in Great Britain except on a very limited scale till 1823. After the repeal of the tax in that year, Mr. James Muspratt erected his celebrated works at Liverpool, adopted the process in its entirety, and succeeded, after overcoming many diffi-

culties, in establishing in Great Britain a chemical manufacture which has since become the most important in the world, and for which nearly 600,000 tons of common salt are now annually required.

The object of the soda-process is to separate the sodium of the salt, and unite it with oxygen to form caustic soda, or, what is more generally done, to unite the sodium with both oxygen and carbonic acid to form carbonate of soda. The several stages of the process are as follows:

First Operation—The Production of Sulphate of Soda.—The decomposition of the common salt is effected by treating it with sulphuric acid, which transforms it into sulphate of soda and hydrochloric acid. The following diagram illustrates the interchange of elements which takes place:



This operation was long conducted in a common Reverberatory Furnace (q. v.), and the hydrochloric acid was suffered to escape into the air. Not only was the acid thus lost, but it destroyed all vegetation in the neighborhood of soda-works, and involved their owners in serious law-suits for damages. The great chimneys of the St. Rollox Works, Glasgow, and Mr. Muspratt's, Liverpool, which are nearly 500 feet high, were erected with a view of curing this evil, but they were found to be ineffectual. One of the most improved furnaces now in use for the purpose is shown in figs. 1 and 2.

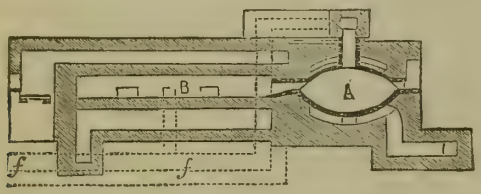


Fig. 1.—Vertical Section of Decomposing Furnace.

They are built in pairs, and in the front part of each there is a shallow cast-iron pan A, nine feet in diameter, with a sheet-iron cover, and so built that the fire may act on the bottoms and sides. Behind this, an oblong brick-chamber, B, 30 feet by 9 feet, is situated, with separate fire-places, and called the salt-cake furnace. Acid flues, *f*, *f*, are led from each compartment of the

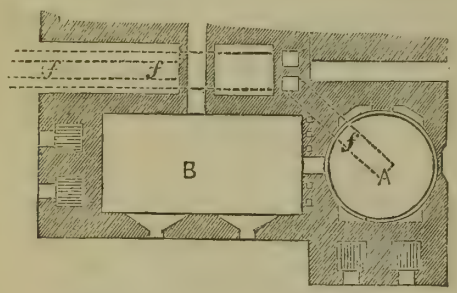

Fig. 2.—Plan of Decomposing Furnace.

double furnace into one main flue, which has its outlet into a condensing tower, to be presently described. Separate flues are also provided for the conveyance of smoke to a main chimney. The furnace is worked in the following way; when it is properly heated, salt to the amount of 10 cwts. is thrown in by an opening, and about 80 gallons of strong sulphuric acid are heated and run in. The mixture, which is well stirred with an iron rake, gradually thickens, and in about an hour the pasty mass, not yet all decomposed, is pushed through the opening into the salt-cake chamber, B. Here it is spread out on the sole, and maintained at a red heat for another hour, when the whole of the hydrochloric acid is expelled, and the conversion into sulphate of soda complete. A pair of furnaces, about one-half larger than those above described, will produce about 19 tons of sulphate of soda in a day, for which 16 tons of common salt are required. At the St. Rollox Chemical Works, Glasgow, about 500 tons of common salt are decomposed weekly.

A very important part of this operation is the condensation of the hydrochloric acid gas which is disengaged in large volumes during the decomposition of the salt. As already stated, it was formerly allowed to escape into the atmosphere. The acid flues convey it to the condensing towers (fig. 3), which are generally filled with pieces of burnt coke, through which a supply of water is kept running. The gas enters at the bottom of the first tower,

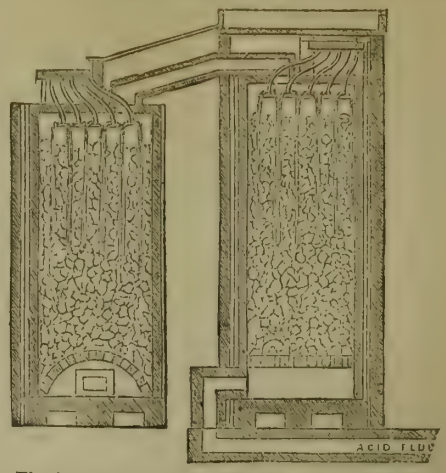

Fig. 3.—Section of Coke Towers for condensing the Hydrochloric Acid Gas.

passes upwards, and descends the second, and is gradually absorbed by the water, forming strong liquid acid, which is run out by openings at the bottom of the condenser. So perfect is the system of condensation now in use at some works, that of the acid produced by 100 tons of pure chloride of sodium which should yield 62 tons, as much as 58½ tons have actually been collected; and it has been instanced as a curious illustration of this in another way, that Mr. Muspratt's great works, which were at one time forced out of Liverpool as a nuisance, have been established there again without causing any protest. Nevertheless such works being still considered obnoxious to their neighborhoods, an 'Alkali Act' was passed by parliament in July 1863, 'For the more Effectual Condensation of Muriatic (hydrochloric) Acid Gas in Alkali Works.' It compels every manufacturer of alkali to secure the condensation of not less than 95 per cent. of the muriatic gas evolved in his works, under a penalty not exceeding £50. This act was amended in 1874 by which copper and sulphuric acid works were placed under similar restrictions. The hydrochloric acid obtained in this process is mostly used in the manufacture of bleaching-powder.

Second Operation—The Conversion of the Sulphate of Soda into Black-ash, called also Ball Soda. This is effected by heating a mixture of sulphate of soda, carbonate of lime, and coal, in a reverberatory furnace. The proportions now used are the same as those first recommended by Leblanc—viz., sulphate of soda, 100 parts; carbonate of lime, 100 parts; carbon (charcoal), 55 parts. But as coal is employed in England instead of charcoal, the quantity used is generally 75 to 100 each of the other two ingredients. The 'balling furnace' used in this operation is shown in fig. 4.

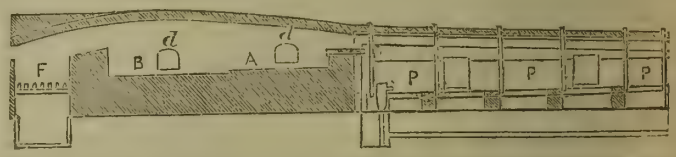

Fig. 4.—Section of Balling Furnace, showing an evaporating pan for Soda-lye in connection with it.

It has two beds, the one being raised a few inches above the other. F is the fireplace, the waste heat from which is usually employed in boiling down the soda-lye as indicated in the section. The charge is thrown into the bed, A, of the balling furnace, after it has been raised to a bright red heat, and remains till it becomes sufficiently heated throughout the whole mass. It is then transferred to the *fluxing bed*, B, which is next the fire, and exposed to a higher heat, when it shortly begins to soften and flux into a mass like dough. In about half an hour the charge is withdrawn in a red-hot state by the working door, and received into iron barrows, where it solidifies into blocks of crude soda, termed ball soda, or black ash. A new kind of balling-furnace, first introduced at the Jarrow chemical works, South Shields, is now becoming extensively used. It differs from the one shown in fig. 4 in having that portion of it for receiving the mixture of sulphate of soda, coal, and lime in the form of a brick-lined iron cylinder, large enough in some instances to decompose 50 tons of the sulphate in 24 hours. This cylinder lies in a horizontal position, and is made to revolve slowly by engine power. The materials are introduced by means of a hopper; the fire-place, which does not rotate, is placed at one

end of the cylinder; and the arrangement for evaporating the lye is somewhat similar to that shown in fig. 4. This rotary furnace admits of the work being much better done than by the older reverberatory furnace, as it not only saves labor but prevents loss of soda by volatilization.

In this process there is first a reduction of sulphate of soda to sulphide of sodium with evolution of carbonic acid; then a conversion of the sulphide of sodium and carbonate of lime into carbonate of soda and sulphide of calcium; and finally the excess of carbonate of lime is reduced by the carbon to caustic lime and carbonic oxide.

Third Operation—The Preparation of Carbonate of Soda from the Black-Ash, by Lixiviation and Evaporation.—For some purposes the crude soda, or black-ash, is used without further purification; for example, in the making of soap. Its lixiviation is effected by the use of a series of iron tanks, or vats, into which it is placed with water. The working of these vats will be most simply explained by the apparatus shown in fig. 5. Several tanks, each of

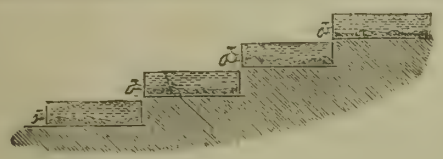

Fig. 5.—Apparatus for lixiviating the crude Soda.

the capacity of 600 gallons, rise above one another in successive stages, so that the liquor of the highest can be run into the next lower, and so on. The black-ash is introduced fresh into the lowest vat; it then passes from vat to vat, and is taken away exhausted at the highest one. The water, on the contrary, comes in fresh at the top, and in passing downwards encounters less exhausted ash in each succeeding vat, and finally passes away from the lowest a fully saturated solution. In most soda-works, the vats are now arranged differently, although the ash may be said to be exhausted in the same way. In the new arrangement, the vats are placed horizontally, and advantage is taken of the fact that solutions in becoming richer become also heavier, so that, although the tanks are all on a level, the water runs through them with what is virtually a downward flow. We have not space to describe minutely this very elegant and economical plan; it will be enough to say that it completely obviates the necessity of lifting the ash from vat to vat, because any two contiguous ones can be made at pleasure the highest and lowest points, and, therefore, those of ingress and egress for the lixiviating fluid. 'Each vat, in due rotation, is emptied and refilled; and thus each in turn successively occupies the highest, lowest, and all intermediate points of the declivity.'

The next stage is the evaporation of the soda-lye, which is conducted in a variety of ways. A common method consists in using the waste heat of the balling furnace, the flame from which passes over the surface of the liquor, as shown in fig. 4. With proper manipulation the soda falls to the bottom, and is raked out at intervals through a side-door, and drained upon a sloping surface.

The soda-salts (chiefly carbonate of soda), thus obtained by evaporation of the lye, contain caustic soda, which requires to be carbonated and a little sulphide of sodium, which it is necessary to get rid of. They are accordingly transferred to a reverberatory furnace, and calcined, at a moderate heat, along with sawdust, or sometimes with small coal, the mixture being stirred with iron paddles. By this treatment, the caustic soda is converted into carbonate of soda, the sulphur is mostly expelled, and we now obtain the *soda-ash*, or alkali of commerce, which generally contains about 50 per cent. of real soda, NaO; the other ingredients, besides the carbonic acid with which it is combined, being chiefly water, sulphur, and common salt. Sometimes it is further purified, and it is then known as *white alkali*.

Soda crystals, or what is commonly called 'washing-soda,' are obtained by dissolving the soda-ash in hot-water, then filtering the solution and boiling it till the specific gravity reaches 1·3, when it is transferred to the crystallizing coolers. Bars of wood or iron are laid across these vessels to sustain the mass of crystals which form, and in ten days at most the crystallization is complete. Crystals of soda are purer than soda-ash, but they are of much less value, weight for weight, because of the large quantity of water which enters into their constitution, amounting to 62½ per cent.

The manufacture of caustic-soda is now an important branch of the alkali trade. For soap-making, bleaching, and several other purposes, carbonate of soda requires to be rendered caustic by quicklime. Manufacturers have, accordingly, taken to the plan of treating the black-ash liquor with hydrate of lime, and so obtain caustic-soda at this stage, instead of sending it into the market as a purified carbonate of soda, for purposes where it requires to be decarbonated again. Another plan consists in mixing a small quantity of chloride of lime, or nitrate of soda, with the soda-lye from the black-ash. It is then concentrated into a strong solution, and finally brought to the state of a fused mass in round iron pots heated to redness. Great attention is now given to the recovery of sulphur from the enormous 'waste heaps' which accumulate at all large alkali works, since there is fully a ton of this 'waste' produced for every ton of common salt used. It consists largely of noxious sulphides of calcium, and is a source both of river and, in warm weather especially, of atmospheric pollution. Mond's process, or some modification of it, is usually adopted. Some chemical changes are first produced in the waste by the action of common air, and the sulphur afterwards precipitated by hydrochloric acid.

Various processes have been at different times proposed, and many have been patented, for making carbonate of soda by other methods than that of Leblanc; but only one of these has had any measure of success. We allude to what is called the 'ammonia process,' patented by Dyer & Hemming in 1838. Several improvements—some of them quite recent—have been made on the original method, and the process is now worked on the large scale at Northwich in Cheshire, and at several places on the continent. It consists in treating a solution of common salt with bi-carbonate of ammonia, by which bi-carbonate of soda is produced, and the chloride of ammonium remains in solution.

Sulphate of soda is made at Widnes, in Lancashire, by Mr. Hargreaves' process of decomposing bricks of common salt with sulphurous acid and steam. This method, by avoiding the direct use of sulphuric acid, saves the expense of nitrate of soda; and owing to the lower temperature, spares the apparatus. See Lomas, *Manual of the Alkali Trade*, 1880.

SODA-WATER. See Aerated Waters.

SO'DIUM (symb. Na, equiv. 23, spec. grav. 0·972) is one of the metals of the alkalies—its oxide being soda. Its properties closely resemble those of the allied metal, potassium. It is of a bluish-white color, is somewhat more volatile than potassium, and further differs from that metal in having a higher fusing-point (about 208°), a greater specific gravity, and in not catching fire when dropped in water (unless the water is heated), although, like potassium under similar conditions, it partially decomposes it and liberates hydrogen; and at the same time communicates a strong alkaline reaction to the solution. If, however, a piece of unsized paper is placed on the surface of cold water, and the sodium be placed on the paper, the metal takes fire, and burns with a deep yellow flame. Strictly speaking, it is the liberated hydrogen rather than the metal which burns, the yellow tint (which is characteristic of the sodium compounds) being due to a little sodium volatilized by the heat, mixing and burning with the hydrogen. When heated in the air, it burns with its characteristic yellow flame, and is converted into soda. When exposed *in vacuo* to a red heat it assumes the form of vapor, and admits of distillation. Like potassium, it must be kept immersed in naphtha, so as to exclude the oxidising action of the air. As a reducing agent, it is little inferior to potassium, and as its combining power is lower, and it is obtained much more cheaply, it may usually be advantageously substituted for potassium in reducing operations. Sodium does not occur in the metallic form in nature, but its compounds are very widely distributed. It is found by far the most abundantly in the form of chloride of sodium (or common salt), but it likewise occurs as albite or soda-felspar, cryolite (the double fluoride of sodium and aluminium, and the principal source from whence aluminium is procured), borax (the biborate of soda), trona (the sesquicarbonate of soda), and Chili saltpetre (nitrate of soda).

The methods of obtaining sodium are similar to those already described for obtaining potassium. The following procedure recommended by Deville is regarded as the best for obtaining it in large quantity. Intimately mix 717 parts of dried carbonate of soda with 175 parts of finely powdered charcoal and 108 parts of finely ground chalk, knead them into a stiff paste with oil, heat them in a covered iron pot till the oil is decomposed, and finally distil them in an iron retort with the precautions which are noticed in describing the preparation of Patassium (q. v.). The object of adding the chalk is to prevent the separation of the charcoal from the carbonate of soda when the latter fuses. This mixture ought to yield nearly one-third of its weight of sodium.

With regard to the history of sodium, it is sufficient to observe that Duhamel, in 1736, discovered that potash and soda (now known to be the oxides of potassium and sodium) were distinct bodies. Sir H. Davy first obtained the metal *Sodium* in 1807. The symbol of this metal, Na, is the abbreviation of *Natrium*, which is derived from *Natron*, one of the old names of native carbonate of soda.

Sodium combines with all the elementary gaseous bodies, and two of these combinations—viz., those with oxygen and chlorine, are of extreme importance and value.

With *oxygen*, sodium forms two compounds—viz., an oxide (NaO) and a peroxide (NaO_2). The latter being of no practical

value, may be passed over without notice. The oxide (soda) was formerly known as *fossil* or *mineral alkali*, to distinguish it from potash, which, from the source from which it was procured, was termed *vegetable alkali*. Anhydrous soda (NaO) is procured by burning the metal in dry air; it is of a yellowish-white color, powerfully attracts moisture, and retains the water so firmly that it cannot be expelled by heat. Hydrated or caustic soda (NaO,HO) closely resembles, both in its properties and in the mode of procuring it, the corresponding potash compound. It is, however, not so fusible as the latter, and is gradually converted, by exposure to the air, into carbonate of soda, which is also an infusible salt in its anhydrous state. Solution of hydrate of soda (or soda lye) is largely employed in the arts. It is prepared by boiling a tolerably strong solution of carbonate of soda in milk of lime until a portion of the filtrate ceases to effervesce on the addition of an acid.

The solid hydrate has a specific gravity of 2·13 and the quantity of anhydrous soda in any solution may be pretty closely approximated to by determining the specific gravity of the fluid at a temperature of 59°. Tables for this purpose have been constructed by Dalton (quoted in Miller's *Inorganic Chemistry*, 2d ed. p. 37), and by Zimmerman (reprinted in the article 'Sodium' in Knight's *English Cyclopædia*).

Many of the combinations of the oxide of sodium (soda) with acids—constituting soda-salts—are of great importance. Carbonic acid forms three salts with soda—viz., a normal carbonate, a sesquicarbonate, and a bicarbonate of soda.

The *Normal or Ordinary Carbonate of Soda* ($NaO,CO_2 + 10Aq$), popularly known as the *Soda* of commerce, is a colorless, inodorous salt, with a nauseous alkaline taste. It crystallizes in large transparent rhomboidal prisms, which contain nearly 63 per cent. of water, but it readily parts with all this water, on the application of heat. The crystals also lose the greater part of their water on mere exposure to the air, when they effloresce, and fall to powder. Water at 60° dissolves half its weight of the crystals, and boiling water considerably more, the solution acting like an alkali on vegetable colors. This salt occurs native in the natron-lakes of Hungary, Armenia, &c., in association with sulphate of soda and chloride of sodium. In other regions it appears in an efflorescent form on the surface of the earth. It is now, however, almost entirely manufactured from sea-salt. See SODA, MANUFACTURE OF.

Sesquicarbonate of Soda ($2NaO,HO,3CO_2 + 3Aq$) occurs native in the form of large, hard, non-efflorescent prisms, in Hungary, Egypt, Mexico, &c., under the name of *Trona* or Natron. When strongly heated, it loses one-third of its carbonic acid, and becomes converted into the preceding salt.

Bicarbonate of Soda ($NaO,HO,2CO_2$) may be formed by passing a current of carbonic acid through a strong solution of carbonate of soda, till saturation takes place, and allowing the mixture to crystallize; or it may be produced on a large scale by exposing crystals of carbonate of soda to a prolonged current of carbonic acid. The bicarbonate crystallizes in four-sided prisms, which require 10 parts of water at an ordinary temperature for their solution. This salt is used largely in medicine. See AERATED WATERS.

Sulphuric acid forms with soda a normal and an acid sulphate.

The *Normal or Ordinary Sulphate of Soda* ($NaO,SO_3 + 10Aq$) has been already described under its synonym of *Glauber's Salt* (q. v.). The acid salt, or *bisulphate* of soda ($NaO,HO,2SO_3$), is of no special interest.

The *Hyposulphite of Soda* ($NaO,S_2O_2 + 5Aq$), occurs in large colorless, striated, rhombic prisms, of a cooling and sweet taste. When strongly heated in the air, it burns with a blue flame. It dissolves readily in water, depositing sulphur if the solution be kept in a closed vessel. It may be obtained by digesting a solution of sulphide of soda on powdered sulphur. The sulphur is gradually dissolved, and forms a colorless solution, which, on evaporation, yields crystals of hyposulphite of soda. This salt is largely employed in photography, and is occasionally prescribed medicinally. Sulphurous acid forms two salts with soda—viz., a sulphite and a bisulphite. The *Sulphite of Soda* ($NaO,SO_2 + 7Aq$) is obtained by passing sulphurous acid over carbonate of soda, dissolving the resulting mass in water, and crystallizing; when the salt is obtained in efflorescent oblique prisms, which fuse at 113°, and are soluble in 4 parts of cold water, the solution having a slightly alkaline reaction, and a sulphurous taste. This compound is commercially known as *Antichlore*, and is largely used in paper-manufactories for the purpose of removing the last trace of chlorine from the bleached rag-pulp. The *Bisulphite* is of no importance.

Nitrate of Soda (NaO,NO_5), known also as *Cubic Nitre* or *Chili Saltpetre*, occurs as a natural product on the surface of the soil of certain South American districts. In most of its properties, excepting its crystalline form, and further in its being deliquescent, it resembles nitrate of potash. It is used to a considerable extent as a manure. The *Phosphates of Soda*, though comparatively numerous, do not call for notice here. See PHOSPHATES. *Hypochlorite of Soda* (NaO,ClO) is at present only known in solution, in which it occurs as a yellowish-green fluid, evolving a smell of chlorine; it has strong bleaching power, and when boiled, becomes decolorized, and evolves chlorine freely. It is formed by passing a stream of chlorine gas through a solution of carbonate of soda, the resulting solution containing the hypochlorite, together with undecomposed carbonate of soda and chloride of sodium. This solution is useful as a bleaching agent, as an oxidizing agent in analytical chemistry, and as a disinfectant agent. There are two *Borates of Soda*, of which the only important one, the *Biborate*, is already described under its ordinary name of *Borax* (q. v.). Various *Silicates of Soda* have been formed. In reference to the properties of these salts, see the articles FUCHS'S SOLUBLE GLASS and GLASS.

The *Haloid Salts* of sodium resemble, in their general characters, the corresponding salts of potash. Of these, by far the most important is *Chloride of Sodium* or *Common Salt*, formerly known as *Muriate of Soda* (NaCl). It occurs naturally in far greater quantity than any other soluble salt. See ROCK-SALT, SEA, WATER. The following are its leading properties: It crystallizes in colorless, transparent cubes, which are anhydrous, soluble in about 3 parts of cold water, and scarcely more soluble in boiling water. A saturated solution has a specific gravity of 1·205, the specific gravity of the salt being 2·125. It is insoluble in pure alcohol, is inodorous, and has a purely saline taste, unmingled with bitterness, unless chloride of magnesium be mixed with it. At a red heat, it fuses, and becomes converted into a transparent brittle mass.

The well-known decrepitation which occurs when salt is thrown on the fire, or otherwise strongly heated, results from the sudden expansion of water mechanically entangled amongst its particles. The uses of this salt have been known from the earliest times. It is an essential constituent of the food both of man and animals. From want of space, we must refer our readers to Liebig's *Letters on Chemistry* (Letter xxviii.) on this subject, in which the functions of salt in the food and in the blood are clearly pointed out. It is regarded as a necessity even by the rudest nations. 'In several countries of Africa, men are sold for salt; amongst the Gallas and on the coast of Sierra Leone, the brother sells his sister, the husband his wife, parents their children, for salt; in the district of Accra (Gold Coast,) a handful of salt, the most valuable merchandise after gold, will purchase one, or even two slaves.'—Note to Liebig's *op. cit.*, p. 413. Chloride of sodium is employed in the process of salting meat, in consequence of its powerful antiseptic properties. Meat thus prepared loses, however, a considerable portion of its nutritive juices, which pass into the brine; and is less digestible than in its natural state. Amongst the purposes for which this salt is mainly employed may be mentioned the manufacture of the various salts of soda, especially the carbonate; the preparation of hydrochloric acid; the glazing of stoneware; the preparation of soap; &c. The other haloid salts—the iodide, bromide, and fluoride of sodium—require no notice.

Sodium has been recently found to enter into various groups of organic bodies. We shall take the sodium-alcohols as an example. When sodium or potassium is gradually added to anhydrous alcohol, the temperature rapidly rises, the metal is dissolved, hydrogen is evolved, and a fusible deliquescent compound is formed, which has received the name of *Sodium-alcohol* (or potassium-alcohol), or of *ethylate of soda* (or potash), its composition being such that it may be regarded as alcohol in which one atom of hydrogen is replaced by one of the metal; as shown in the equation:

$$\overbrace{2(C_4H_6O,HO)}^{\text{Alcohol.}} + 2NaO = \overbrace{2(C_4H_6O,NaO)}^{\text{Sodium-alcohol.}} + 2H.$$

The action of sodium or potassium on the other alcohols is of an analogous nature.

The *tests* for the salts of sodium are not very satisfactory, because the metal forms scarcely any insoluble compounds. A salt of sodium is usually concluded to be present when, the absence of all other bases having been proved, a saline residue remains, which, with bichloride of platinum, yields yellow striated prisms ($NaCl,PtCl_2 + 6Aq$) by spontaneous evaporation. Before the blowpipe, the salts of sodium are known by the intense yellow which they communicate to the outer flame, and if a weak alcoholic solution of one of the salts is burned, a similar yellow tint is communicated to the flame. Spectrum analysis is too delicate to be of much practical use. Bunsen estimates the amount of soda that may be thus detected at the 195,000 000th part of a grain; and considering how universally diffused chloride of sodium is, this fractional amount is hardly likely to be absent.

In conclusion, the *medicinal uses* of the sodium compounds require our notice. They will be considered alphabetically. *Acetate of Soda* is a mild diuretic, similar in operation to acetate of potash, for which it may be substituted. It may be given in doses vary-

ing from a scruple to a couple of drachms. *Arseniate of Soda* ($2NaO,HO.AsO_5 + 14Aq$) is serviceable in periodic affections, chronic skin-diseases, and the cases in which arsenic is generally employed in medicine. It has all the advantages of arsenite of potash, and seems to cause less irritation of the stomach. It is best given in the form of *Pearson's Solution*, which consists of one grain of the crystals of this salt dissolved in ten drachms of distilled water. Dose, from 20 minims, very gradually increased to two drachms, three times daily. The *Liquor Sodæ Arseniatis* of the Pharmacopœia is much stronger; its dose being from three to ten minims. Paper impregnated with a solution of arseniate of soda sweetened with sugar is sold as a poison for flies. *Biborate of Soda*, or *Borax*, is employed principally as a tropical astringent, and is used with advantage in aphthous eruptions of the mouth and throat. *Bicarbonate of Soda* is a most popular remedy in cases of dyspepsia, but its use is highly injurious when there are phosphatic deposits in the urine. See PHOSPHATIC DIATHESIS.

Neligan strongly recommends the external application of an ointment consisting of 20 or 30 grains of the bicarbonate, with an ounce of cold cream, in cases of papular and vesicular eruption of the scalp. *Carbonate of soda* is not employed as an antacid so frequently as the bicarbonate, in consequence of its disagreeable taste; but in the dried state, when deprived by heat of its water of crystallization, it is much used as an alterative. In dyspepsia attended with acidity, a combination of the dried carbonate with blue pill and rhubarb pill is often extremely useful. As it has a very acrid taste, it should be combined, if given in powder, with some bland substance, such as Compound Tragacanth Powder. *Solution of Chlorinated Soda* (known also as *Solution of Chloride of Soda, Chlorinated Soda, Hypochlorite of Soda*, and *Labarraque's Disinfecting Liquor*) is preferable to hypochlorite of lime in destroying noxious effluvia, as the salt which is left does not deliquesce, while chloride of calcium is very deliquescent. It may be applied locally to foul ulcers, either in lotion (2 drachms to 8 ounces of water), or as a poultice with linseed meal and boiling water. *Phosphate of Soda* ($2NaO,HO,PO_5 + 24Aq$), known also as *Tasteless Purging Salt*, is a mild saline purgative, with a far less unpleasant taste than sulphate of magnesia. It is especially adapted as a purgative for persons affected with deposits of red gravel (lithic or uric acid) in the urine. The dose varies from half an ounce to two ounces, and it may be given in broth, to which it imparts only a saline taste. *Sulphate of Soda*, and *Tartrate of Soda and Potash*, have been already described under their ordinary names of *Glauber's Salt* (q. v.) and *Rochelle Salt* (q. v.).

SODOM AND GOMO'RRAH, two ancient cities of Syria, almost invariably spoken of in conjunction in the Bible, and forming with Admah, Zeboiim, and other towns, the 'cities of the plain,' which, on account of the enormous wickedness of their inhabitants (the nature of which is indicated in the term Sodomy), are said to have been overthrown—not submerged—by some terrible convulsion of nature. Modern writers on sacred topography are not agreed as to the precise site to be assigned to these cities, no trace of which now remains; the majority holding that they stood on the southern shore of the Dead Sea, near the salt hill of Usdum; while others, again, apparently with more countenance from the Scripture narrative (Gen. xiii. 10—13), maintain that Sodom, Gomorrah, and the other 'cities of the plain,' stood in the 'circle or plain of the Jordan,' east from Bethel and Ai, near where the river discharges itself into the Dead Sea. The popular belief, that the cities were miraculously overwhelmed by the waters of the Dead Sea, and that their remains may still be seen at the bottom, is an idle tale of superstitious travelers, uncountenanced either by fact or by the terms employed by Scripture to describe the catastrophe.

SODOM, APPLE OF, the name given to the fruit of a species of *Solanum* (q. v.). But it seems that the true APPLE OF SODOM, or MAD APPLE, of the shores of the Dead Sea, mentioned by Strabo, Tacitus, and Josephus, and described as beautiful to the eye, but filling the mouth with bitter ashes if tasted, is a kind of gall, growing on dwarf oaks, and produced by a species of gall-insect, which has received the name of *Cynips insana*. These galls are about 2 inches long, and 1½ inch in diameter, of a beautiful, rich, glossy, purplish-red color, and filled with an intensely bitter, porous, and easily pulverized substance, surrounding the insect. They are attached to the twigs in a curious manner, different from other galls, the narrow end 'rising upwards on each side, and bending inwards, so as to clasp the extremity of the twig somewhat like a pair of wide and curved nippers.'

SODOMY, an unnatural crime, is punishable with penal servitude for life, or any term not less than ten years, and the attempt to commit it is punishable with penal servitude from three to ten years. In Scotland it is still nominally a capital offence, but never punished except by penal servitude and imprisonment.

SODOR AND MAN, BISHOPRIC OF. See HEBRIDES and MAN.

SOEST (pronounced SHOST), a town of Prussia, province of Westphalia, 36 miles south-east of Münster by railway, was, during the middle ages, a Hanse-town and fortress, and, in point of commercial importance, one of the foremost cities of Germany, with a pop. of from 60,000 to 70,000. Now, however, it is only the shadow of its former self; but relics of its ancient splendors still survive in its numerous and magnificent churches, of which the finest is the 'Meadow Church,' restored in 1850. Its municipal law, the *Jus Susatense*, was the oldest in Germany, and served as the model for the other imperial free-towns, Lübeck, Hamburg, &c. At present, S. has some trade in corn, and extensive breweries. Pop. (1880) 13,985.

SOFA'LA, or, as the old geographers sometimes wrote it, CEFOLA, is the name given rather indefinitely to that portion of the south-east coast of Africa extending from the Delta of the Zambezi (Quama of old geographers) as far south as the Rio Maneci or Delagoa Bay, or from lat. 18° to 26° S., although some modern geographers consider Cape Corrientes as its southern limit. This stretch of coast now comprehends the Portuguese captaincies of Rio de Senna, Tetè, Sofala, and Inhambane, besides the regions round Delagoa Bay, nominally under the control of the crown of Portugal, the extent inland being generally limited by the mountain region which runs parallel to the coast of Southern Africa, and forming a belt of low country about 150 miles wide, full of swamps, densely wooded, and generally unfavorable to European life.

S., in common with the remainder of the coast of Eastern Africa, was conquered by the Arabs between the 8th and 12th c.; it was visited in 1480 by Pedra Cavalho, a Portuguese captain, from Abyssinia, before the route by sea to India was discovered. In 1500, the Portuguese, under Albuquerque, commenced making settlements on this coast, and built a strong fort on an island in the mouth of the Rio de Sofala, near a town which was founded 200 years before by the Arabs, and which still exists, although in a very decayed state. The inland region at the back of the coast district, now occupied by the Transvaal Boers towards the south, or by Moselikatse and his Amatabele to the north, and stretching away northward for an indefinite distance, formed the celebrated though mythical empire of Monomotapa, the accounts of which by the early travelers are perfectly marvelous. S. was considered by the old geographers as a very rich, gold-producing country; and was judged by some to be the Golden Ophir to which King Solomon every three years sent a fleet of ships; and, indeed, it seems to have derived its name from the Greek *Sophira*, by which Ophir is translated in the Septuagint. Lopez tells us that in his time the inhabitants related that the gold-mines of S. afford yearly two millions of metrigals—every metrigal accounted for a ducat. Whatever may have been its former reputation, S. has long ceased to be a gold-producing-country to any considerable extent.

An old writer says: 'Great wild elephants overspread the country, which the natives neither know how to tame nor manage; nor are lions, bears, stags, or harts and boars fewer; besides, sea-horses sport themselves in the Quama.' This description is pretty accurate, even at the present day, if we omit the bears, and call the stags antelopes; for the elephants, rhinoceroses, and other large game, driven away from the highlands in the interior by the pursuit of the Cape hunters, have descended into the coast lowlands, where the dense bushy nature of the country, and its extreme unhealthiness, protect them from extermination, although such keen sportsmen as M'Cabe, Chapman, and Edwards have not feared to follow them there.

The most northern regions of S. are the captaincies of Rio de Senna and Tetè, formerly called Matuka, which include the country on the right bank of the Zambezi, sloping down from the Malappo Mountains, which bound its basin on the south. The principal places are Tetè, in lat. 16° 12′ S., long. 31° 50′ E.; and Senna, in lat. 17° 30′, long. 34° 40′. The middle region comprises the captaincy of S., the seat of government being at the town or fort of that name, in the Bay of Massangane; lat. 20° 12′, long. 34° 40′. Inhambane is the name of the most southerly captaincy, in lat. 23° 51′, and long. 35° 20′. There are other inconsiderable Portuguese factories along the coast at Imhampoora, south of Inhambane, Mambone, and Lorenco Marquez, in Delagoa Bay, where a Portuguese governor resides.

Although nominally under Portuguese rule, yet the authority of that government rarely extends outside of the walls of the miserable forts held by its agents. It is computed that on the whole of the Portuguese settlements on the east coast of Africa there are not more than 500 colonists of European birth. Trading parties of Dutch Boers from the Transvaal Territory occasionally visit the factories at Inhambane, Sofala, and Lorenco Marquez, to purchase articles of European manufacture in exchange for ivory, wax, timber, &c. The natives, generally, are of the negro type, gradually approximating to the more intellectual Zulu Kaffir as we proceed from the Zambezi to Delagoa Bay.

The principal exports from this region are ivory, bees-wax, hides, and rhinoceroses' horns; while a considerable clandestine

traffic is said to be carried on in slaves. Considerable amounts of gunpowder, lead, coffee, and European clothes find their way up from the coast to the Boer settlements in the highlands of the interior. The coast-line is generally low and sandy, and dangerous on account of shoals and sandbanks. A group of islands, called Bazaruta, lie off the coast north of Cape St. Sebastian, in lat. 22° S. The best harbor is that of Imhambane, and ships may ascend to the town, about 8 miles from the mouth of the river. The harbor at the mouth of the Rio de Sofala is difficult of access on account of its bar.

SOFFIT, a small ceiling, formed into panels, as over windows, ingoings of doors, staircases, &c.

SOFTENING AND INDURATION are terms used to express a pathological diminution and augmentation of the consistence of the tissues or organs of the body. These changes may arise from inflammatory action; but softening may also be induced by causes totally distinct from inflammation, as, for example, from a deficient supply of blood, from scrofula or cancer, or from long continued functional inactivity (as in the case of paralyzed muscles). Amongst the parts liable to both softening and induration are the brain and spinal cord, the heart, the lungs, the serous and mucous membranes, the liver, the spleen, the kidneys, the uterus, and the bones and cartilages.—For further details on the subject, the reader may consult the English translation of Vogel's *Pathological Anatomy*.

SOFT-GRASS (*Holcus*), a genus of grasses having a lax panicle, two-flowered spikelets, with two nearly equal glumes. The species are not numerous. The English name is derived from the soft and abundant pubescence of the British species, which are two in number, CREEPING S. (*H. mollis*), and WOOLLY S. or MEADOW S. (*H. lanatus*), both perennial grasses, and both very common. Meadow S. is found most abundantly on damp, moorish, or peaty soils, on which it is sometimes sown, as it yields abundant herbage; but it is very inferior to some other grasses, and therefore unsuitable for rich meadows and pastures. Creeping S. is generally found on dry sandy, or other light soils; and very much resembles Meadow S., but is still more downy, and of smaller size. The roots somtimes extend 5 or 6 feet in a season. The roots contain much nutritious matter, and are a very acceptable food to horses and cattle, but especially to hogs, which grub them up for themselves when they have opportunity.

SOIGNIES, a town of Belgium, province of Hainault, 22 miles south-west of Brussels by Railway. Its church of St. Vincent Maldegaire, founded in the 10th c., if not earlier, is probably the oldest in Belgium. S. has breweries, distilleries, trade in stone and lime, and large fairs. Pop. 7000.—Some miles to the north-east, in the province of South Brabant, lies the forest of S., at whose southern extremity is situated the famous field of Waterloo.

SOILS consist of the disintegrated materials of the hard crust of the earth, mixed with decayed vegetable matter. This disintegration is effected partly by the chemical action of oxygen, carbonic acid, and the other acid or alkaline substances brought by the atmosphere to bear upon rocks, and partly by the wearing action of water in a fluid state or in the form of glaciers, or by its bursting force when frozen in deep clefts. The soils produced by running water, floods, and tides, are found along the banks or at the mouths of rivers, and are generally called *alluvial soils;* those produced by glacier-action are known as *drift soils;* and both are generally found at a great distance from the rocks of whose disintegrated materials they are composed. But by far the greater mass of soil has been produced in the other way above mentioned, by the gradual weathering of rock under atmospheric influence; and it is generally found adjoining or overlying the rocks from which it has been produced. Immediately beneath the soil or stratum of earth which affords nourishment to plants, is a mass of earth or rock, unmixed with decayed vegetable matter, to which the term *subsoil* is applied. The subsoil may or may not be similar in its geological constitution to the soil; and from the absence of vegetable matter, is generally lighter in color than the latter.

Every species of rock has produced its soil; but the older formations, from their greater hardness and power of resistance to atmospheric action, produce, in proportion to their exposed surface, less soil than do the Secondary and Tertiary groups. The fertility of soils has no relation to the chronological succession of the strata of the earth's crust; thus, igneous rocks produce a naturally fertile soil, though they seldom become thoroughly disintegrated; metamorphic or transition rocks furnish one of poor quality, as does also the greater portion of the Silurian system; while to the vast mass of the Secondary group of deposits, especially the Devonian system, with its old red sandstone, and limestone, and marl beds, the mountain limestone of the Carboniferous system, and the new red sandstone of the Permian and Triassic systems, belong some of the richest tracts in Great Britain, though numerous members of the same group supply barren and ungrateful soils.

The Lias, and Oolitic, and Wealden systems generally supply clay-soils of considerable fertility, but of the densest texture and most intractable character; soils formed from the cretaceous group are extremely variable in quality; but when the chalk is largely mixed with sand or clay, they exhibit a considerable degree of fertility; however, they have one great general defect, that of not sufficiently retaining moisture. The soils produced from the Tertiary formations possess no general characteristics, being sometimes extremely fertile, and again almost wholly barren; and, in short, we are bound to come to the conclusion, that the mere geological composition of soils affords no very reliable criterion by which their economic value can be estimated; the same rock which produces the almost barren soil of Argyleshire, weathers into the fertile soil of the Channel Islands; and to the old red sandstone is due at once the rich soil of Hereford, Monmouth, Moray, and Strathmore, and some of the most barren heaths and moors in Scotland. These apparent anomalies are no doubt largely produced by the various action of heat, moisture, and other meteorological agencies.

But however soils may vary in a geological point of view, they are all resolvable into a few elements—viz., the various compounds of aluminium, iron, manganese, the four alkaline metals, the seven alkaline earths, and the four organic elementary substances. These 18 bodies supply, singly or in combination, all the constituents necessary to the growth of plants, each of them having its own portion of the plant to sustain—the silica producing strength and rigidity in the stems; alumina giving tenacity to the soil, and so rendering it a stable support; magnesia perfecting the seeds; iron absorbing oxygen and ammonia from the atmosphere, and giving it up as required; and so on. Of these ingredients, silica, alumina, lime, along with matter derived from organic bodies, constitute the bulk of the soil; the other ingredients existing only in minute quantity, and hence is derived the common quadruple division of soils into *silicious or sandy, argillaceous or clayey, calcareous,* and *humous.*

It is not sufficient that soil possesses all the ingredients necessary for rendering it fertile, or that these ingredients are in a sufficiently comminuted state to enable them to be absorbed; there is besides a certain physical or mechanical condition necessary. Thus, for example, a soil which possesses too great a proportion of silica, is too little retentive of moisture, and has not sufficient consistency of texture to be an effective support of tall plants; one in which calcareous matter abounds is also too dry a soil; while if alumina predominates, it is generally too retentive of moisture; and a great excess of the last-named ingredient renders it so extremely tenacious, as to be almost incapable of reduction to a proper mechanical state. The soil which is physically most perfect is composed of about equal proportions of the two great ingredients, silica and alumina, and is generally known as *loam,* being distinguished into *clay loam* or *sandy loam,* according as the alumina or silica sensibly predominates. But the physical qualities of soils do not wholly depend upon their composition; they are also largely affected by the depth of the soil itself, and the quality of the subsoil. Should the soil and subsoil be both retentive, or both porous, the defects of these states as to dryness or moisture are considerably increased; if porous and retentive soils of good depth rest upon subsoils of a contrary character, the defects of the former are to a considerable degree amended. But the advantages and disadvantages of these conditions must to a very large extent be judged by the prevalent character of the climate, a somewhat porous subsoil in a cold moist district being generally preferable, and *vice versâ.* Each of these classes of soils, when possessed of the chemical ingredients in quantity sufficient for the wants of plants, and of a texture favorable to their growth, excels in the production of certain species. Thus, the clay loams are unequalled for the production of wheat and beans; the sandy loams for barley, rye, and the various root-crops; while both are well suited for the growth of the other cultivated plants, or for perennial pasture.

Besides the calcareous and marly soils which may be, according to circumstances, classed as a clayey or sandy soil, rarely the former, there is the humous soil, which possesses characteristics peculiarly its own. It is not devoid of consistency like the sandy, or retentive of moisture like the clayey soils, but in its natural state is spongy and elastic in texture, of a remarkably dark color, and when dried, becomes inflammable, and even when much improved by culture, retains these characteristics in a considerable degree. It consists wholly, or to a great extent, of vegetable matter, and is found in perfection in forests of ancient date, as the woods of America, and in the peculiar form of Peat (q. v.) in many parts of the world. In its ordinarily decomposed condition, it is at once the richest of soils; but in the state of peat it calls for long-continued drainage, and the application of decomposing agents, before it can be rendered of service in the production of crops.

Improvement of a soil must, then, as is seen from the foregoing considerations, be effected either by supplying the substances required by plants to a soil which is deficient in them, by altering its depth and texture, and by removing excess, or supplying deficiency of moisure. The first of these objects is effected by the introduction and incorporation of Manures (q. v.) with the soil, care being taken that the manure contains the requisite ingredients, and in such a condition as to be assimilable by plants either directly or indirectly through the soil, and by the more thorough exposure of the soil to the action of the atmosphere; the second is effected by the admixture of marl or clay with sandy, chalky, or peat soils, of lime, ashes, or burned clay, with tenacious clay soils, or by the mixture of the subsoil (if differing in quality) with the soil by means of the subsoil plough, or by more complete surface-tillage, and free exposure to the action of frost; and the third is accomplished by Drainage (q. v.) and Irrigation (q. v.). The fertility and chemical composition of a soil may be approximately determined by inspection of its color and texture; but more accurately, as well as its dryness or moisture, excess or defect of silica and alumina, by the predominance of certain species of wild plants or weeds.

SOISSONS, a town of France, in the dep. of Aisne, stands in a fertile vale on the banks of the river Aisne, about 65 miles north-east of Paris. S. is the key of Paris for an army invading France from the Netherlands, and is the meeting-point of six military roads. The principal building is the cathedral, founded in the 12th c., the library of which contains many rare MSS. There are also some remains of the great castellated abbey of St. Jean des Vignes, where Thomas à Becket found refuge when in exile. Quite near to S. is an institute for 'deaf and dumb,' which occupies the site of the famous abbey of St. Médard, where Clothaire and Siegbert were buried. S. has manufactures of linen, woollens, and cottons. Pop. (1876) 10,754. S. is one of the oldest towns in France, and was celebrated even in the time of the Romans, when it bore the names first of *Noviodunum*, and afterwards of *Augusta Suessionum;* hence its modern name of Soissons. It was the last Roman stronghold in Gaul that withstood the arms of Clovis, who here overthrew Syagrius, the Roman commander, in 486, and made it the seat of the Frankish monarchy, which it long continued to be.

SOKOTO, a kingdom of Africa, in Sudan, to the south-west of Lake Tchad, and separated from it by the state of Bornu (q. v.). Area, 117,000 sq. miles. The inhabitants, who are mostly of the Fulbe tribe, are numerous. A formidable military force is maintained.—*Sókoto*, the capital, stands on the Zirmie, an affluent of the Sókoto, which flows into the Quorra. Its market is of great importance; it trades in raw silk, glass-wares, and perfumery, carries on extensive and famous manufactures of leather goods, and has from 20,000 to 22,000 inhabitants.

SOLANACEÆ, or SOLANEÆ, a natural order of exogenous plants, mostly herbaceous plants and shrubs, but including a few tropical trees. The leaves are mostly alternate, undivided or lobed, without stipules. The flowers are regular, or nearly so; the calyx and corolla generally 5-cleft; the stamens generally five. The fruit is either a capsule or a berry, mostly 2-celled. The plants of this order are mostly natives of tropical countries, a small number extending into the temperate and moderately cold climates of both hemispheres; in the coldest regions they are entirely awanting. They are mostly distinguished by an offensive smell, and by containing in greater or less abundance a narcotic, poisonous substance, usually associated with a pungent principle, and some of them are amongst the most active poisons. Sometimes the narcotic substance predominates, as in Mandrake (q. v.) and Henbane (q. v.); sometimes the pungent substances predominates, or is alone present, as in Cayenne Pepper (*Capsicum*); sometimes both are present in more or less equal proportion, as in Tobacco, Thorn-apple or Stramonium, and Belladonna. The fruit is generally poisonous; but that of a considerable number of species, in which acids and mucilage predominate, is eatable as, for example, the berries of the Winter Cherry and other species of Physalis, those of the Egg-plant (q. v.) and some other species of *Solanum*, and of the Love-apple (*Lycopersicum*). The tubers, which occur in a few species, contain much starch, and serve as an article of food, of which the Potato is the chief example. The seeds of all contain a fixed oil, which in the south of Germany is expressed from the seeds of the Belladonna itself.

SOLAN GOOSE. See GANNET.

SOLA'NO. See SIMOOM.

SOLA'NUM, a genus of plants of the natural order *Solanaceæ*, containing a great number of species, which are distributed all over the world, but are particularly abundant in South America and the West Indies. Some of the species are herbaceous, others are shrubs; some of them unarmed, and some of them spiny; many covered with a down of starlike hairs. The flowers are in false umbels, or almost in panicles; seldom in racemes, or solitary. The anthers open by two holes at the top. The berries are two-celled, and contain many smooth seeds. The species of this genus almost always contain in all their parts a poisonous alkaloid, *Solanine*, in greater or less quantity, sometimes so much that the leaves or the berries cannot be eaten without danger, whilst in a few species the quantity present is so small as to be insignificant, and these parts are eaten freely, being agreeable and harmless. By far the most important of all the species is *S. tuberosum*, the POTATO (q. v.), in which, however, Solanine is found in considerable quantity, so that not only the herbage, but the juice of the raw tubers, is unwholesome. Of the species with eatable fruit, the principal is S. *melongena*, the EGG-PLANT (q. v.)—The only British species are *S. dulcamara*, the BITTERSWEET (q. v.), and *S. nigrum*, the COMMON NIGHTSHADE (q. v.), both of which possess poisonous and medicinal qualities. The berries, leaves, bark, and roots of various species are employed for different medicinal uses in the warm countries of which they are natives; but their properties have not yet been sufficiently investigated. The berries of *S. saponaceum* are used as a substitute for soap.

SOLAR, an upper chamber or loft. The only private apartment in the old baronial halls was so called. It was placed over the pantry, at one end of the hall, and served as parlor and sleeping apartment for the baron and his family.

SOLAR CYCLE. See PERIOD.

SOLAR SYSTEM. The planets and comets which circle round the sun combine with it to form a system to which is given the name of *solar* or *planetary* system. It is probable that each star is the center of an analogous system. This, however, is merely a matter of speculation, and in no way practically concerns us; but it is different with the solar system. No change of much magnitude can take place in the elements of the planets without having effect on the earth and its inhabitants, on account of the mutual attractions of the planets for each other; in fact, they appear as members of one isolated family, bound together by common ties, which could not be ruptured in the case of one individual without communicating a general shock to the others. The various members of the solar system are noticed under PLANETS, PLANETOIDS, COMET, SUN, MOON, SATELLITES, METEORS; and their motions are treated of under GRAVITATION, CENTRAL FORCES, PRECESSION, &c., so that it only remains here to give the more interesting numerical facts connected with them, which can be done most conveniently in a tabular form.

Name.	Diameter in Miles.	Density Earth's being = 1.	Mass, Sun's being = 1.	Distance from Sun in Millions of Miles.	Period of Revolution in Days.	Velocity in Orbit—Miles per Hour.	Velocity of Rotation at Equator—Miles per Hour.

SOLAR MICROSCOPE, an instrument for producing magnified images of minute objects on a screen, through the agency of the sun's rays. The tube of the microscope is conical, and is fastened to the interior side of a closed window-shutter over a hole in the latter; a reflector, placed at the hole so that the rays of light may fall on it, is so adjusted as to throw them along the tube. They are then collected by a powerful double convex lens, and thrown on the object, which is inserted into the tube at the focus of the lens by a slit at the side. After passing the object, the rays again pass through a single lens, or a combination of lenses, make their exit from the tube, and fall on a screen, on which they depict a magnified image of the object. We have here supposed the object to be so translucent as to allow of the passage of rays through it. Should it be opaque, the rays of light reflected from the mirror are caught by the double convex lens, which concentrates them on another mirror near the opposite end of the tube; they are thence reflected upon the back of the object, and diverge on the system of lenses at the mouth, which form the image. Instead of the sun's rays, the oxyhydrogen lime-light (and more recently the electric light) has been employed, its rays being thrown on the double-convex condenser by means of a concave reflector, in whose focus the piece of burning lime or marble is situated. The instrument is hence often called the *Oxyhydrogen Microscope.*

SOLA'TIUM, in Scotch Law, means compensation for wounded feelings, and is something over and above the ordinary pecuniary value of the damage. In England, such a ground of damages is not in strict principle admitted, but in practice there is no substantial difference.

SOLDER, an easily fusible alloy used for joining metals. Solders are of various kinds, suited to different metals. They always require to be used with a flux, such as borax, resin, chloride of zinc, sal-ammoniac, &c. The following are the principal solders: *Pewterers' solder*—bismuth, 2 parts; lead, 4 parts; tin, 3 parts. This can be used for coarse work by the direct application of naked fire; but for fine work, requiring the protection of a muffle-furnace, the composition must be bismuth and lead, of each one part; tin, 2 parts. *Plumbers' solder* for coarse work—tin, 1 part; lead, 3 parts. For finer work—tin, 2 parts; lead, 1 part. *Spelter solder*—12 parts zinc to 16 parts of copper. *Soft spelter solder*—equal parts of copper and zinc. When solders are applied in the common work of plumbers and tinmen, a tool called the soldering-iron is used: this is made red-hot, and forms a convenient means of applying fire direct to the solder and flux Although called the soldering-iron, the portion of the tool to be heated must be of copper. In many manufactures, a flame produced by a mixture of atmospheric air and coal gas is used to melt the solder; and for fine work, such as jewelry, the common blowpipe is often used.

SOLDIER is one who enters into an obligation to some chieftain or government to devote for a specified period his whole energies, and even if necessary his life itself, to the furtherance of the policy of that chief or government. The consideration may be immediate pay, or prospective reward; or the contract may be merely an act of loyal devotion. The acknowledgment of the service by the employer constitutes the man a recognized soldier, and empowers him to take life in open warfare, without being liable to the penalties of an assassin and a robber. The fact of being mercenary, that is, of receiving wages for killing and being killed, does not render a soldier's trade less honorable. He bears arms that others may be able to do without them: he is precluded by the exigences of military training from maintaining himself by peaceful occupation; and it is therefore but fair that those whom he protects should support him, and give him, over and above actual maintenance, reasonable wages for the continual risk of his life. If a man willingly enlist himself as a soldier in what he believes to be an unrighteous cause, it is an act of moral turpitude; but when once enlisted, the soldier ceases to be morally responsible for the justice or iniquity of the war he wages; that rests with his employer. Obedience, implicit and entire, is his sole virtue. The maxim is: 'The military force never deliberates, but always obeys.' See ENLISTMENT, MARTIAL LAW, WAR, &c.

SOLDO. See SOLIDUS.

SOLE (*Solea*), a genus of Flat-fishes (*Pleuronectidæ*), of an oblong form with a roundish muzzle, which almost always advances beyond the mouth; the mouth twisted to the side opposite to that on which the eyes are situated, which is usually the right side, although individuals of the same species are found having the eyes and color on the left side; the teeth very small in both jaws, but only in the under part of the mouth (the *side* opposite to the eyes); the lateral line straight; pectoral fins on both sides; the dorsal and anal fins long, and extending to the tail, but distinct from the tail-fin.—The COMMON S. (*S. vulgaris*) is a highly esteemed fish, abundant on the British coasts where the bottom is sandy, and of which great quantities are brought to market. The London market is supplied chiefly from the south coast of England, the soles there attaining a larger size than those of more northern coasts. They are caught by trawling, very seldom with bait. The S. is in condition for the table during the whole year except five or six weeks in February and March, its spawning-time. The Common S. is found on all the coasts of Europe, except the most northern. It has been known to attain a size of 26 inches long, and almost 12 inches broad, weighing 9 pounds; but a S. of less than half that weight is reckoned very large. The

Common Sole (*Solea vulgaris*).

upper side of the body is of an almost uniform dark brown; the scales small, rough to the touch, and ciliated at the edge; the lower side is white. The S. sometimes ascends rivers to a considerable distance from the sea, and seems to thrive at least as well in fresh as in salt water, a fact of which advantage has not yet been taken for the stocking of fresh-water ponds. It breeds freely enough in fresh water.

The only other British species of true S. is the LEMON S. (*S. pegusa*), which is sometimes taken with the Common S. on the south coast of England, and more rarely in more northern parts. It is paler in color than the Common S., and broader and thicker in proportion. It is equally esteemed for the table.—The name S. is popularly extended to several genera recently separated from the true soles. In *Brachirus*, the dorsal and anal fins are united with the tail fin; but, as in *Solea*, there are pectorals on both sides. To this genus belongs the ZEBRA S. (*B. zebrinus*) of Japan, remarkable for the zebra-like stripes which cross its whole body.—In *Monochirus*, the pectoral fin is developed only on the upper side. To this genus belong the VARIEGATED S. (*M. variegatus*) and the LITTLE S. or SOLENETTE (*M. linguatulus*), both found on the British coasts, but of little importance, on account of their small size.—In the genera *Achirus* and *Plagusia*, of which there are no British species, the pectorals are wanting on both sides.

SO'LECISM. A solecism is the term applied to any violation of the grammar or idiom of a language, or of the usages of society. It is said to be derived from the city of Soli in Cilicia, whose inhabitants spoke very bad Greek, in consequence of their intercourse with the Cilician natives, and provoked the fastidious Athenians to coin the epithet.

SO'LEN, a genus of lamellibranchiate molluscs, the type of a family, *Solenidæ*, remarkable for the wide gaping of the shell at both ends, and the large and muscular *foot*. In the genus S., the shell is remarkably elongated, its apparent length being, however, more strictly its breadth. From its form, the names RAZOR-SHELL and RAZOR-FISH are often given to it. The species are

Solen, or Razor-fish (*S. siliqua*).

numerous, and inhabit the sands of all seas except in the coldest parts of the world. Some of the tropical species have shells of great beauty. The solens burrow in sand, making their hole straight down, and ascending and descending by means of their foot, which is capable of being elongated and contracted to bore a passage for the animal, and to drag it through. They are used for food, and also by fishermen for bait. To obtain them, a hooked iron implement is used. Another method is to drop a quantity of salt on the mouth of the hole, which causes them to come up, when they are quickly seized. The most common, and one of the largest British species, *S. siliqua*, is about an inch in *length*, and eight inches in breadth. It is perfectly straight. Another common British species, *S. ensis*, is curved like a sword.

SOLENHOFEN LITHOGRAPHIC STONE, a famous deposit of limestone of Upper Oolite age, which from its fine-grained and homogeneous texture is admirably adapted for lithographic purposes. It occurs near Aichstadt in Bavaria, and has been exten-

sively quarried since the invention of lithography. The quarrymen work upon the lines of stratification, which are beautifully parallel, and all the fossils are found upon the natural surfaces of the beds, and present an impression and cast in almost every instance. The rock is quarried to a depth of 80 or 90 feet. It is of special interest to the geologist from the singular assemblage of fossil remains which are preserved in it with wonderful minuteness. The most delicate tracery of the wings of the dragon-fly is often as perfect as in living specimens. The rock is of marine origin, and while lithologically it has a strong resemblance to the White Lias of Britain, its fossils correlate it to the Kimmeridge Clay. These are chiefly ammonites, nautili, crustacea, winged insects, fishes, and pterodactyles. But the most singular fossil is

Remains of Archæopteryx in Solenhofen Stone.

one which has only recently been brought to light. A single feather was first found, and some months after, the bones of a feather-covered animal, which was considered by its first describers to be a lizard; but Professor Owen showed, on incontrovertible grounds, that it is a true though very anomalous bird. The specimen, which, with the exception of the head, is almost entire, is now at South Kensington. It formed the subject of an elaborate memoir by Professor Owen. He named it *Archæopteryx macrura*. It was pronounced the oldest bird of which any remains had yet been found; though the Connecticut footprints pointed to a still earlier fowl. (For its relation to ancient American birds, see Marsh's *Odontornithes*, a monograph on the extinct toothed birds of America). Another specimen of the *Archæopteryx* was afterwards found at Solenhofen, and is now at Berlin. The *Archæopteryx* was about the size of a rook.

The anomalous structure which induced the earlier observers to make it a reptile, and some that followed to imagine it as a transition form between the reptile and the bird, is the tail, which, instead of consisting of a few shortened vertebræ united together into a coccygean bone, as in all known birds, recent or fossil, was formed of twenty elongated vertebræ, each of which supported a pair of quill-feathers. But this departure from the bird type is not so anomalous as it at first sight appears, for in the early embryonic condition of the bird, the vertebræ are distinct and separate, and the anastomosis which invariably takes place in the subsequent development of the embryo, does not occur in the *Archæopteryx*, so that it may be considered to exhibit the temporary embryonic condition of the bird as a permanent structure; and that this is the true position of this singular fossil is further established by the existence of other features which are found only in birds. These are the ornithic structure of the wings and legs, the occurrence of feathers, which are confined to birds, and the existence of a merry-thought (furculum), which is found in no other class of animals. An elevation on the surface of the slab containing the fossil is believed by many to be the cast of the interior of the skull, and it corresponds remarkably in size and form with the cast from the skull of a rook.

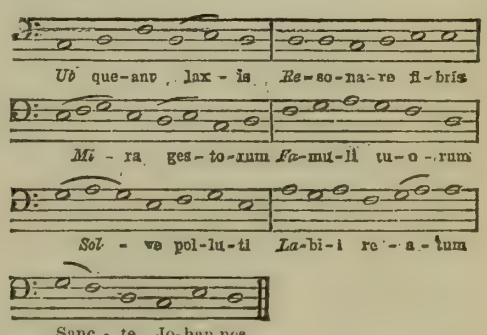
SO'LENT, the name of the western portion of the strait that intervenes between the Isle of Wight and the mainland of England. At Hurst Castle, which guards its entrance on the southwest, the S. is less than a mile in breadth; and along this narrow passage the tide flows with a rapidity which at certain times no boat can stem. The castle itself consists of a central tower or keep, surrounded by several smaller towers, and mounted with heavy guns.

SOLEU'RE (Ger. *Solothurn*), a canton in the north of Switzerland, bounded on the W. and S. by Bern, and on the N. and E. by Basel and Aargau. Area, 300 sq. m.; pop. (1876) 77,803, mostly Roman Catholics. The greater portion of the canton is fertile and well cultivated, especially along the banks of the Aar. Even the rugged and hilly districts are sources of wealth on account of their fine pasturage. Besides grain, the principal products of S. are fruit, wine, flax, and cotton. Cherry-brandy is a very important article of trade. The manufacture of iron, glass, pottery, hosiery, and recently of watches, is carried on to a considerable extent.—S. entered the Swiss Confederation in 1481 along with Freiburg. Its constitution is liberal. The legislative body, or parliament, is the Grand Council, consisting of 106 members, the whole of whom are, since 1856, chosen directly by the people, who have besides a veto on the laws passed by the council. The executive is chosen by the council, and consists of 5 members.

SOLEURE (Ger. *Solothurn*), capital of the canton, is situated on the Aar, 16 miles north-north-east of Bern by railway. The scenery in its vicinity is among the loveliest in Switzerland, The Aar flows through the town, dividing it into two unequal parts, which are connected by two wooden bridges. The most notable building is the cathedral of St. Ursinus, with a cupola and façade of Corinthian columns, reckoned the most costly cathedral in Switzerland. S. has some manufactures, but derives its chief industrial importance from its transit-trade. Pop. (1880) 7668. Near to S. are the baths of Weissenstein.

SOLFATA'RA (Fr. *Soufrière*, Ger. *Schwefelgrube* or *Schwefelsee*), the Italian name for such volcanoes as, having become less active than volcanoes in an actual state of eruption, only exhale gases. The most notable of them are found in Italy, in the Antilles, in the interior of Asia, and in Java. The S. of Pozzuoli, near Naples, is an irregular plain, 1368 feet long, and 1310 feet broad, almost surrounded by broken hills of pumaceous tufa, the ancient walls of the crater. From the crevices of the rocks, steam or noxious gases, chiefly sulphuretted hydrogen, mixed with a minute quantity of muriatic acid and muriate of ammonia, exhale. In the cracks and fissures of the rocks, sulphur, alum, and sulphate of iron abound. The vapors exhaled are used as medicinal baths, and huts, constructed of boards, have been erected in which the baths may be obtained. The Soufrière of Morne-Garou, in the isle of St. Vincent, Lesser Antilles, about three miles in circuit, and over 500 feet in depth, has in its center a cone, the summit of which is covered with sulphur.

SOLFE'GGIO, in Music, seven syllables, which are sometimes used as a nomenclature for the seven notes of the scale. In singing, the art of applying these syllables to the notes as an exercise for the learner, is called *Solmisation*. The syllables are *ut* (or *do*), *re, mi, fa, sol, la*, and *si*. The first six are the commencement of the lines of an ancient monkish hymn to John the Baptist, which had this peculiarity, that the first syllable of each line was sung to a note one degree higher than the first syllable of the line that preceded, so as to present the type of a scale:



These syllables are said to have been first made use of by Guido of Arezzo, in the 11th c.; and Le Maire, a French musician of the 17th c., added to them *si*, for the seventh of the scale. When applied to the key of C, their equivalents, in the ordinary musical nomenclature, are:

Do	re	mi	fa	sol	la	si	do
C	D	E	F	G	A	B	C.

These syllables may, however, according to the more modern practice of teachers in this country, be applied to other keys, with *do* always as the keynote, so as to express not the absolute pitch of a note, but its relation to the keynote; and thus used, they are thought to be of service to the learner in keeping prominently be-

fore him the principle that there is but one scale in music, which is raised or lowered according to the pitch of the key. Different variations in the way of using the syllables have recently given rise to various supposed short and easy modes of teaching singing, the best-known of which is Mr. Curwen's system of 'Tonic Sol-mization,' where the ordinary notation of the staff, with its lines and spaces, is entirely rejected, and a notation substituted which is formed of the solfeggio syllables, used to express not pitch but relation to the keynote. One disadvantage of this and similar schemes is the entire withdrawal of the direct indication of the pitch of the sounds to the eye, by the notes ascending as the sounds ascend, which is so beautiful a feature of the common notation. And even if it be granted that the first rudiments of music can, as has been asserted, be taken up with remarkable ease by the pupil who learns on the tonic sol-fa system, it is undeniable that as soon as he comes in contact with notes of different lengths, or begins to modulate from one key to another, he is beset with serious difficulties. There is, in addition, the further objection to the system, that the pupil thus taught is shut out from the whole world of musical literature, a disadvantage which is not compensated by having a few elementary difficulties smoothed away, which experience shows that children of the most mediocre capacity can overcome.

SOLFERI'NO, a village of Northern Italy, province of Brescia, 20 miles north-west of Mantua, with 1400 inhabitants. It stands on a hill, and has a tower called the Spy of Italy (*Spia d'Italia*), from which the whole plain of Lombardy may be seen. There, in 1796, the French conquered the Austrians. On June 24, 1859, S. was again the scene of an overwhelming victory obtained by the French and Italians over the Austrians.

SOLICITOR. See ATTORNEYS.

SOLICITOR-GENERAL, the name given to one of the law-officers of the crown. The Solicitor-general of England has powers similar to those of the Attorney-general (q. v.), to whom he gives aid in discharging his functions. During the absence of the Attorney-general, he may do every act and execute every authority of that officer. He is, *ex officio*, one of the Commissioners of Patents.

The Solicitor-general of Scotland is one of the crown counsel, next in dignity to the Lord Advocate (see ADVOCATE, LORD), and exercising all his functions along with him. His office cannot be traced further back than the Union. Like the Lord Advocate, he has the privilege of pleading within the bar. All proclamations for the observance of days of public fasting and thanksgiving are addressed to the Solicitor-general.

SOLICITOR TO THE TREASURY, an officer who acts as attorney for the government in all legal proceedings. He has also to act as solicitor for the three secretaries of state, the Privy Council Office, the Board of Trade, the Mint, the War Office, the Stationery Office, and for all the other principal departments for which no solicitor is specially appointed.

SOLIDUNGULA. See EQUIDÆ.

SOLIDUS, the name by which the old Roman 'aureus' (equivalent to £1, 1*s*. 1½*d*., according to the present value of gold) was known after the time of Alexander Severus; but during the reign of Constantine the Great, its value was diminished in the ratio of 8 : 5, and so remained till the end of the empire. The weight of these later solidi was fixed at $\frac{1}{72}$th of an ounce, the gold being 23 carats fine, and the alloy mostly native silver. The 'solidus,' or 'solidus aureus,' was adopted by the Franks under the Merovingians and Carlovingians (at 87 to the Roman pound) till the time of Pepin, who suppressed it; but another solidus of silver, or 'solidus argenteus'—the $\frac{1}{20}$th of the libra or pound—which had been used only as a money of account, was soon after made a coin. In after-times, this 'sol,' or 'sou,' like all other coins, underwent an infinity of variations in fineness and value (see LIVRE). On the introduction of the decimal system (1793) into France, the sou was abolished, and a piece of 5 centimes ($\frac{1}{20}$th of a franc) substituted, but the name continued in common use, and the old sous were retained in circulation. The solidus also appears in the *soldo*, which was a coin in use in Northern and Central Italy, and was essentially the same with the sou.

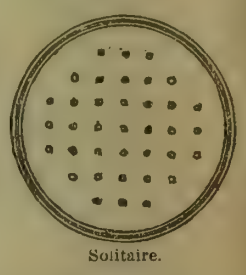
SO'LINGEN, a town of Prussia, province of the Rhine, and government of Düsseldorf, capital of a circle of the same name, is situated on a height 13 miles east-south-east of Düsseldorf, and not far from the river Wupper. It is a very old place, and has long been famous for its steel and iron ware manufactures, especially sword-blades, helmets, cuirasses, knives, scissors, which are exported to all parts of the world, and rival the excellence of English wares. In the town and circle of S. there are about 3000 workshops, employing over 10,000 hands, and producing yearly half-a-million hand-bells, knives in millions of dozens, scissors, revolvers, &c. S. hand-bells have been famous since the middle ages, and are sent to the most distant lands. Pop. (1880) 16,940.

SOLITAIRE (*Pezophaps*), a genus of birds of the Dodo (q. v.) family (*Didinæ*), but differing from the dodos in a smaller bill and longer legs. Like the dodos, the only species of this genus, of the existence of which there is any evidence (*P. soliataria*), seems to be now extinct, and to have become extinct in very recent times. It inhabited the island of Rodriguez, an island about 15 miles long by 6 broad, situated about 300 miles to the east of Mauritius, and appears to have been peculiar to that small and lonely island, where it was abundant at the beginning of the 18th century. Rodriguez was uninhabited till 1691, when a colony of French Protestant refugees settled on it, under the command of François Leguat, who, in his *Voyages et Aventures*, has left an interesting and trustworthy account of the solitaire. He describes it as a large bird, the males sometimes weighing 45 lbs.; taller than a turkey, the neck a little longer in proportion, and carried erect; the head of the male without comb or crest, that of the female with something like a widow's peak above the bill; the wings small, and the bird incapable of flying, but only using the wings to flap itself or to flutter when calling for its mate, or as a weapon of offence or defence; the bone of the wing being thickened at the extremity so as to form a round mass, about the size of a musket-bullet, under the feathers, and to increase the force of the blow given by it; a roundish mass of feathers instead of a tail. He further describes the plumage as very full and beautiful, not a feather out of its place, so there can have been no feathers with unconnected webs, as in the ostrich. He says the bird is called S. because it is very seldom seen in flocks. He tells us that the bird is with difficulty caught in the forests, but easily on open ground, because it can be outrun by a man; and that its flesh is very good to eat.—But the S. seems to have completely disappeared from Rodriguez, which is now a British settlement. Bones have been lately found in large quantities, and, since Professor Newton's visit to Rodriguez in 1865, the skeleton has been entirely reconstructed. Skeletons are preserved in the South Kensington Museum, in the Royal College of Surgeons, and in the Museum of the University of Cambridge.—The figure here given is derived from a rude cut in Leguat's work.

Solitaire (*Pezophaps solitaria*).

The name S. was originally given to a species of dodo inhabiting Bourbon, also extinct, of which the remains have never been found; and was applied by Leguat to this bird, in a mistaken belief of its being the same. See *Strickland and Melville on the Dodo and its Kindred*.

SOLITAIRE, a species of game or rather puzzle, which, as the name denotes, is played by only one person. The apparatus for the game consists of a round or octagonal flat board, indented with 33 or 37 hemispherical hollows, as in the figure, and 33 or 37 balls, one in each hollow. The process of the game consists in removing one ball from the board, and then, having created a vacancy, capturing one of the balls adjoining by causing the one behind to leap over it into the vacant hollow; there are now two vacancies, and the game is continued in the same manner by capturing ball after ball, till only one remains, when the game is *won*. Should more than one be left, and they be so isolated as not to be liable to capture by each other, the game is *lost*. This puzzle may be solved in an immense number of ways; one of the prettiest modes consists in removing the central ball, and so capturing the others that the last ball shall be in the center.



Solitaire.

SOLLE'R, a small town and seaport of the Balearic Isles, in Majorca, 14 miles north of Palma. It exports oranges and wine, and contains 7000 inhabitants.

SOLMISATION. See SOLFEGGIO.

SOLO, a term used in musical compositions of several parts, whether vocal or instrumental, to indicate those voices or instruments that are to perform alone or in a more prominent manner, as *soprano solo*, *violino solo*. The plural, *soli*, is used when two or more voices or instrumental parts are to be performed together, such parts, of course, never being doubled.—A composition for a single instrument accompanied is also termed a solo.

SOLO'FRA, a small city of Southern Italy, province of Avellino. Pop. 5376. It is situated on the Apennines, and is surrounded by wooded mountains.

SO'LOMON (Hebr. Shĕlômô, Salomon, Salomo, Suleiman, derived from *shalom*, peace = Peaceful, like Germ. Friedrich), the second son of David and Bathsheba; successor of the former on the throne of the Israelitish empire for forty years (1015—975 B C.*). Nothing is known of his youth except that he was probably educated by Nathan (or Jehiel). Equally uncertain is the age at which he succeeded to the crown of his father. That he was older than twelve or fourteen years, as some traditions tell us, seems certain. The way in which his succession to the throne during the lifetime of his father was brought about, to the exclusion of his elder brother Adonijah, is not undeserving of the name of *coup d'état*, which has been bestowed upon it (see the Scripture narrative). Having, by the execution of Adonijah and the leaders of his faction, secured his dominion against internal foes, he, with complete disregard of the Mosaic law, set himself to seek foreign alliances, and with this view married as his principal wife the daughter of Pharaoh, probably of Psusenes (Vaphres?), of the twenty-first dynasty. Besides her, however, he had a vast number of wives—700 'princesses,' and 300 'concubines'—the greatest part of whom were recruited from nations with whom an alliance had been strictly prohibited.

Having inherited fabulous wealth, and further adding to it enormously from his own multifarious revenues, so that 'silver was nothing accounted of in his days,' it became necessary that a new organization corresponding to this unheard of splendor should be introduced. Accordingly, we hear of 'Princes,' i. e., great officers of state, not before heard of. The two counsellors of David's time disappear, in order probably to make room for a whole body of legal advisers; the prophets are no longer to be found among the dignitaries of state, but new military charges are created instead. The immense accumulation of treasure also allowed the execution of a number of public works in Jerusalem, which now first assumed the magnificence and station of a capital. A new wall with fortified towers was erected around it; and the Queen's Palace—'the House of the Forest of Lebanon'—with a long hall joined to it by a cedar porch, called the 'Tower of David,' outside of which a thousand golden shields were suspended, and within which the king sat, in all his imperial splendor, to pass judgment, were built under his immediate orders. His banquets, at which all the vessels were of gold; his stables, with their four (or forty) thousand stalls; his gardens and parks and summer retreats, were such as to dazzle even eastern fancy. Twelve commissaries, distributed in the different provinces, had each in his turn to furnish the means of sustaining this prodigious household. The dominion of S. extended from Thapsacus, on the Euphrates, to Gaza on the Mediterranean. The country was in the profoundest state of peace; the treasures accumulated by David appeared inexhaustible; and the popularity of the king, who listened to the meanest of his subjects, and gave judgment according to that wisdom, for which he had asked in his vision at Gibeon, in preference to any other gift, and which has remained proverbial from his day to ours, was naturally at first very great. Everything, moreover, was done to develop and increase the national wealth and welfare. The rich internal resources were developed, and commercial relations of the most extensive nature established.

Through the port established at Ezion-Geber, at the head of the Gulf of Elath, an outlet was gained to the Indian Ocean; and the alliance with Phœnicia, then under the sway of Hiram, gave an energetic impulse to these foreign expeditions. Manned with Tyrian sailors, the Israelite fleets went to 'Ophir,' and brought back, in exchange for their own exportations, 'gold and silver, apes and peacocks, ivory and spices;' and the rest of the strange and precious produce of India, Africa, Spain, and other regions, possibly even our own coasts.

According to his promise, S., in the fourth year of his accession, commenced the building of the Temple on Moriah, after the model of the Tabernacle, wherein he was aided by Hiram, who not only sent him timber, but architects and cunning Phœnician artists in wood and stone and metals. In the eleventh year of his reign it was completed, and solemnly inaugurated in the following year—at which occasion prodigious numbers of sacrifices were slaughtered. Thirteen years more having been spent in the construction of the 'House of the Forest of Lebanon' (the royal palace), other buildings and fortifications—among them that of Palmyra—are recorded to have been undertaken by the king, who, far from wishing further to extend his dominions, was only bent upon keeping his frontier safe from the raids of the neighboring hordes, and for that purpose alone kept up an unprecedently large army.

The fame of S. could not but spread far and near. The splendor of his court and reign, heightened by his personal qualities, his wisdom and erudition—for he was not only the wisest but also the most learned of men—brought embassies from all parts to Jerusalem to witness his magnificence, and to lay gifts of tribute at his feet. The queen of Sheba's expedition and presents are well known; and as many Arab kings made him annual presents of a no less splendid nature, his income from different sources was calculated, in round numbers, at the enormous sum of 666 golden talents. That people of Moses, which was to know no other wealth than flocks and the fruits of the soil, had suddenly become a people of wealthy merchants, of soldiers, and of courtiers—and it did not profit by the change, chiefly through the bad influence of the king himself and his court. The army and the public buildings absorbed the resources of the provinces. In the Temple, erected for the purpose of the true worship of Jehovah, S. sacrificed three times a year; but nevertheless, to please his concubines, he allowed, and perhaps himself indulged in, the rites of polytheism on the heights, thereby setting the worst example to his subjects, sufficiently eager already to worship foreign deities. His exaggerated polygamy fostered immorality and licentiousness among the people; and, worst of all, the wise and gentle monarch, as his treasure got exhausted, began, toward the end of his reign, to lay the yoke, which hitherto had lain only on his Canaanite subjects, upon the Israelites themselves. And he thus became, to all intents and purposes, an eastern despot—selling part of his dominion to raise money, and trying to break the spirit of the nation by forced services and corporal chastisements.

Left by the 'prophets,' probably since his open and revolting infidelity with regard to the national worship, his advisers were chiefly insolent young courtiers, who awed even his aged counsellors into silence, and from that time forth a storm began to gather over the land. The priests were on the side of the malcontents, and a vague talk of a general rising, which actually found utterance by a 'prophet' in the face of S., was heard throughout the country. Ahijah of Shiloh predicted, as Samuel had done to David, the partial dominion to the Ephraimite Jeroboam, who had to flee for his life to Egypt. But notwithstanding these internal mutterings, and the open revolts of one or two subject chiefs, such was the prestige both of David's and S.'s name, that the king was allowed to die in peace.

S. has been supposed to be the author of Canticles (q. v.), Ecclesiastes (q. v.), Proverbs (q. v.), besides works on Science which are said to be lost. But he is also to be considered the prime cause of the final and decisive downfall of the Jewish commonwealth for all historical times. His wisdom turned into folly, his justice into tyranny, raised a smouldering discontent which only awaited his death to break out into open flames of revolt and internal wars. His character presents the lamentable spectacle of genius gone astray; and many have been the discussions on the part of learned theologians in old and late times as to whether or not there was any hope of his 'salvation.' His name and his glory, however, will, notwithstanding the shadows that fall over his latter days, remain immortal, whether we look at the striking picture of him given in Scripture, or to the more gorgeous kaleidoscope of Eastern legends revolving round the golden name of Suleiman: the Lord and Master of all animate and inanimate beings under the sun, the most beautiful, the most wealthy of all created men, and whose wisdom was as much without limits as were his riches and power.—See for such legendary accounts of S., Weill's *Biblical Legends*, the *Targums*, the *Koran*, Lane's *Arabian Nights*, D'Herbelot, Ginsburg, Fürst's *Perlenschnüre Suleiman Nameh*, in 70 books, ascribed to a Turkish poet, Firdusi, &c.

* There is some discrepancy among investigators about this date; the beginning of his reign being fixed variously at 1009, 1025, 990, &c.

SOLOMON ISLANDS, a chain of islands in the Malay or Indian Archipelago, between New Britain on the north-west and the Queen Charlotte Islands on the south-east; lat. 4° 50′—11° 50′ S. Area estimated at 10,000 sq. m.; pop. thought to be considerable, but not ascertained. The natives are partly Negrilloes, partly Malays, and are still in the condition of savages.

SOLOMON'S SEAL (*Polygonatum*), a genus of plants of the natural order *Liliaceæ*, differing from Lily of the Valley (q. v.) chiefly in the cylindrical tubular perianth, and in having the flowers jointed to their flower-stalks. There are three Brititsh species. The COMMON S. S. (*P. multiflorum*) is found in woods and copses in many parts of England, and in a few places in Scotland. It has a stem about two feet high, the upper part of which bears a number of large, ovate-elliptical, alternate leaves in two rows. The flower-stalks are generally

Solomon's Seal (*Polygonatum multiflorum*).

branched; the flowers not large, white, and drooping.—The NARROW-LEAVED S. S. (*P. verticillatum*) is a rare British plant, only found in a few places in Scotland. The leaves are whorled.—The ANGULAR, or SWEET-SMELLING S. S. (*P. officinale*) is also rare in Britain, and is found only in England. It more nearly resembles the Common S. S., but is smaller, and has greenish, fragrant flowers. All these species are common in many parts of Europe. They are very similar in their properties. The young shoots of *P. officinale* are eaten by the Turks like asparagus. The root is white, fleshy, inodorous, with a sweetish, mucilaginous, acrid taste. It contains *Asparagin*. It is a popular application to bruises, to prevent or remove discoloration, and its use is well known to those who are too apt to get a black eye now and then. A kind of bread has been made of it in times of scarcity. The berries are emetic and purgative.

SO'LON, the most famous of all the ancient Greek lawgivers, was a native of Athens (born about 638 B.C.), and belonged to one of the most distinguished families of Attica. His father, Execestides, having seriously impaired his income by improvidence, S. was obliged while still young, to embark in trade. At first, however, S. comes before us as an amatory poet. His earliest appearance in the field of politics was occasioned by the contest between Athens and Megara for the possession of Salamis. By force of artifice, S. revived the martial spirit of his countrymen, which had sunk under the effect of repeated disasters, obtained command of a body of volunteers, and conquered the island (*circa* 596 B.C.), in which, along with others, he obtained a grant of land. Henceforth his public career is conspicuously noble and honorable. He figures as a wise and unselfish patriot, seeking earnestly, and not in vain, to compose the distractions, partly social and partly political, that rent his native city. The Athenians generally had thorough confidence in his integrity; and in 594 B.C. he was chosen archon or chief magistrate, and received unlimited permission to act as he saw best for the good of the state. In short, to borrow a phrase from Roman history, he was invested with dictatorial power. The nature and extent of the Salonian legislation has been the subject of much criticism in modern times, and Mr. Grote, in particular, has made it very clear that the 'later ancients' (Plutarch and Diogenes Laërtius), on whom we are obliged to rely for almost all our information about S., are full of confusions, misapprehensions, and contradictions, and that it became a habit among them to mythically attribute to the great Athenian every bit of wise legislation whose paternity they could not discover.

In order to alleviate the wretchedness arising from the existing relations of debtor and creditor, which was no longer supportable, and was likely to create a social war, S. proposed and carried a notable measure—the *seisachtheia*, or 'disburdening ordinance' (from *seio*, to 'shake off,' and *achthos*, a 'burden')—which received its name from its design—viz., to lighten the burden of debt that weighed down the *Thetes*, or lower classes. How this was effected, is far from being correctly explained by Plutarch, and the reader who wishes to have the most rational solution of the matter must consult Grote's *History of Greece* (vol. iii.). From redressing the greivances of a class, S. proceeded, at the solicitations of his countrymen to remodel the constitution; and here, too, the qualities that are popularly associated with his name shine out conspicuously. Abandoning the semi-civilized theory which regards the nobles as alone worthy of citizenship, and of the honors of public office in the state, he introduced the timocratic, or rather the plutocratic principle—classifying citizens according to their wealth or property; the effect of which was not to wrest *all* power or dignity from the hands of the *Eupatridæ*, or well-born class, but only to give a portion of it to others who might be as wealthy, and therefore, presumably, as intelligent and cultivated as they. Such a reform has been compared to that previously effected by Servius Tullius in the constitution of ancient Rome; and there is at least a striking resemblance in the method, if not in the design, of the two reforms. See ROME. S. distributed the citizens into four classes. The first embraced all those whose yearly income reached 500 medimni; the second, those of between 300 and 500 medimni; the third, those of between 300 and 200 medimni, and the fourth, those whose income fell below 200 medimni. The first three classes were liable to *direct* taxation; the fourth not; but all were liable to *indirect* taxation.

With regard to the *Boule*, or Deliberative Assembly of Four Hundred, it would seem that S. left it the strictly aristocratical body that he found it. Its power, however, was practically limited by a new *ecclesia*, or assembly of the four classes, whose ratification was necessary to all measures originating in the *Boule*, or 'Upper House.' On the other hand, the *ecclesia* itself could originate nothing, and thus the Attic aristocracy and the Attic plebs could mutually check each other's assumptions. The part of S.'s legislation relating to the industrial pursuits of the citizens appears to have been as excellent and well considered as the rest, but the number of his special enactments is so great that we cannot afford space to mention them. It is enough to state that they embraced almost every subject of social importance; and the best testimony to their value lies in the fact, that when Peisistratos violently overthrew the political constitution established by his kinsman, he allowed his social legislation to stand. See PEISISTRATOS.

The story of S.'s leaving Athens for ten years, after he had completed his labors as a lawgiver, and traveling into foreign countries, may be, and probably is historical, but the details are untrustworthy; and in particular, the celebrated incident of his interview with Crœsus will not suit the requirements of chronology, and must be relegated to the domain of historic myths. During his absence, the old dissensions among the Athenians broke out, and when he returned, S. struggled in vain to repress them. A strong hand, as well as a wise head, was needed, and the conspiracy of Peisistratos was quite as much one against anarchy as against the constitution. After S.'s defeat, he withdrew into private life, but occasionally assisted with his advice his bold, ambitious, and able kinsman, who had so effectively crushed the Athenian 'disorderlies' of all parties. The date of his death is uncertain.

SOLO'R ISLANDS, THE, lie east of Flores, between 122° 56′ 30″—124° 25′ E. long., and belong to the Netherlands Residency of Timor. Besides several groups of smaller islands, they consist of Solor, with an area of 105 sq. m., and a pop. of 15,000; Adanara, 302 sq. m., pop. 36,000; Lomblem, 520 sq. m., pop. 120,000; and Pantar, 275 sq. m., with 60,000 inhabitants. Solor and Adanara are separated from Flores by narrow straits, Lomblem and Pantar lie in succession further east.

Solor has little cultivated land, the natives being good sailors, and chiefly employed in fishing. Much sulphur and saltpetre are found, from which gunpowder is made. The women weave coarse fabrics for clothing, and exotic cotton has lately been planted with success. Edible nests are extensively collected. In all the villages on the coast, markets are statedly held, and numerously frequented. The natives near the sea are Malays, friendly to the Dutch, a few of them Christians, the others Mohammedans. Those of the interior are Alfoors, wild and warlike, who use shield and bow, sword and firearms. Adanara is governed by an independent rajah. It is a lovely island, having hills and dales, picturesque villages, and cultivated fields. The people are Malays, partly Mohammedans and partly Roman Catholics. Lomblem is also beautiful, the native Malays; those of Pantar being Papuans.

The S. I. are mountainous; the volcano Lobetolle, in Lomblem, is 4914 feet high; and the mountains of Pantar, 3332. They are clothed to their summits with forests. In 1851, the Portuguese relinquished all claim to these islands, which are now governed by the military commander at Larantooka, in the east of Flores; a Dutch postholder being stationed at Lawajang, the chief place of Solor.

SO'LSTICE (Lat. *solstitium*, from *sol*, sun, and *sto*, I stand), that point in the ecliptic at which the sun is furthest removed from the equator, and where he is consequently at the turning-point of his apparent course. There are two such points in the ecliptic, one where it touches the tropic of Cancer, the other where it touches that of Capricorn. The former is the summer, and the latter is the winter solstice to those who inhabit northern latitudes, and *vice versâ*.—The term is also employed to signify the *time* at which the sun attains these two points in its orbit, the 21st of June and about the 21st December.

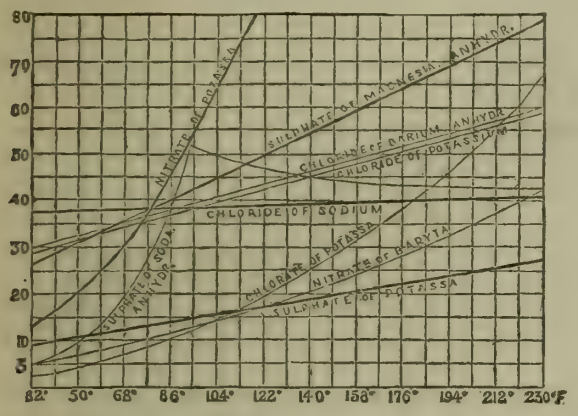
SOLT, a town of Hungary, 48 miles south of Pesth, on a branch of the Danube. Pop. (1880) 5700.

SOLU'TION. A substance is said to undergo solution, or to become dissolved, when the force of adhesion between it and a liquid in which it is immersed is sufficient to overcome the force of cohesion between the solid particles. Thus sugar or salt is dissolved by water, camphor or resin by spirit of wine, and silver by mercury. The liquid which effects the solution is termed the *solvent*, or sometimes the *menstruum;* and some solutions have special names—for example, the term *syrup* is applied to a solution of sugar in water, and *tincture* to a solution of a solid in alcohol. If a solid body be introduced in successive small portions into a definite quantity of a liquid capable of dissolving it, the first portions disappear the most rapidly, and each successive portion dissolves more slowly than its predecessor, until a point is reached at which the liquid ceases to possess any further solvent power. When this occurs, the forces of cohesion and adhesion are balanced, and the liquid is said to be *saturated*.

Solution is promoted by increasing the extent of surface in a solid, or by reducing it to powder. An elevation of temperature, by diminishing cohesion, will generally also increase the solvent power of the liquid; but there are exceptions to this rule—as, for instance, in the case of lime and its salts, water just above the freezing-point dissolving nearly twice as much lime as it does when boiling. A compound of lime and sugar, very soluble in cold

water, is separated from the solution almost completely, if heated to boiling. But the most remarkable case of the kind occurs in sulphate of soda (Glauber's salt), which in its crystalline from dissolves in about ten times its weight of ice-cold water, and rapidly becomes more soluble as the temperature rises until it reaches 91°; from this point until the solution boils, the solubility slightly decreases, the boiling liquid retaining only about four-fifths of the quantity which was dissolved at 91°. Carbonate and seleniate of soda, and sulphate of iron, exhibit the same peculiarity in a less marked degree. 'These anomalous results may be partly explained,' says Dr. Miller, 'by the consideration that heat diminishes the force of adhesion as well as that of cohesion. Generally speaking, cohesion is the more rapidly diminished of the two, although not uniformly so; and in these cases it would appear that the adhesive force decreases in a greater ratio than the cohesion of the saline particles' (*Chemical Physics*, 3d ed. 1863, p. 72).

The accompanying diagram shows the unequal solubility of various of the more common salts in water of different temperatures. The *lines of solubility* cut the verticals raised from points indicating the temperature upon the lower horizontal line, at heights proportional to the quantities of salt dissolved by 100



parts of water. For example, 100 parts of water dissolve—at 32°, 8 parts, at 122°, 17 parts, and at 212°, 26 parts of sulphate of potash. Water which has been saturated with one substance, that is, which refuses to dissolve any more of that substance, will often continue to dissolve others. In true or simple solution, the properties both of the solid and the solvent are retained. When, however, any chemical action ensues between the solid and the liquid, the resulting solution commonly presents perfectly new and distinct features; as, for example, when the metals are dissolved by acids, or oils by the alkalies (as in soap-making). For the solubility of the gases in water, we must refer to the article GASES.

The uses of solution in laboratory processes are numerous. By the difference in degree of their solubility, we can separate one substance from another; and by dissolving a body we can purify it either by filtration or crystallization. Moreover, when it is required that two bodies shall react on one another, they do so with incomparably more force in their dissolved than in their solid state.

SOLVENT. See SOLUTION.

SOLWAY FIRTH—in its upper part best regarded as the estuary of the river Esk; in its lower, as an inlet of the Irish Sea—separates the north-west of Cumberland from the south of Scotland. Its entire length, until lost in the Irish Sea, is calculated at 33 miles; its average breadth for the first 12 of these is not more than 2¼ miles, but afterwards it gradually, although irregularly, increases to upwards of 20. The principal rivers flowing into it, besides the Esk, are the Annan, Nith, Dee, and Urr, from the north or Scottish side; and the Eden and Derwent from the south or English side. The most striking feature of the S. F. is the rapidity with which its tides ebb and flow. The spring-tides are peculiarly swift and strong—the wave rushing in from 3 to 6 feet high, and at the rate of 8 to 10 miles an hour, occasionally inflicting serious damage on the shipping; while after it has retreated, great stretches of the bed of the firth are left bare, and in some places one can even cross over from the English to the Scottish shore. The salmon-fisheries of the Solway are valuable.—*Solway Moss* is a district of Cumberland about 7 miles in circumference, lying west of Longtown, and immediately adjoining Scotland. As its name implies, it was once a bog, but is now drained and cultivated. It is historically notable as the scene of a battle between the English and Scots in 1542, when the latter were defeated. Here also, on 13th November 1771, an extraordinary disaster occurred. The boggy ground, surcharged with moisture—the effect of heavy rains, rose, swelled, and burst like a torrent, sweeping along with it trees and houses, and destroying some 30 small villages.

SOLYMAN (SULEIMAN) II., surnamed 'THE MAGNIFICENT,' the greatest of the Turkish sultans, was born in 1496; and in September 1520, succeeded his father, Selim I. (q. v.), who had carefully initiated him into the secrets of Ottoman policy. At the commencement of his reign, he restored a large amount of unjustly confiscated property, and removed from office all who were unfit for the proper discharge of their duties. After having suppressed the revolt of the governor of Syria, he exterminated the Egyptian Mamelukes, and concluded a treaty with Persia. The foolish insolence of the Hungarian court next drew him thither with a powerful army, and Belgrade, the key of that country, was captured (1521). He next drove the Knights of St. John from Rhodes (1522) and for three years following, devoted himself to improvements in the administration; but his attempts at military reform provoked a rebellion of the janizaries, which he saw no other means of quelling than by engaging them in a war with Hungary. He gained the signal victory of Mohacz (1526), and continuing his resistless course, took Buda and Pesth; but he was recalled by the news of a rebellion in the east, and retreated down the Danube to Constantinople, committing frightful ravages on the way. In 1529, he was summoned to Hungary in aid of his protégé, King John Zapolya, who was contesting the crown with Ferdinand, and accordingly invaded that country with a mighty army, capturing and destroying as he went, and laid siege to Vienna, but after various unsuccessful assaults, he was compelled to retreat. Two years afterwards (1531), he again appeared in Hungary; but his progress this time was checked by Charles V. in person, who had come with the imperial army of 250,000, in aid of his brother. In 1535, he concluded with Francis I. the famous treaty which opened the commerce of the Levant to the French flag alone.

In 1540, the long and desultory contest between the Turks and Imperialists for Hungary was ended in favor of the former, who took complete possession of the country. After this, the alliance between the French and Turks began to bear fruit; the combined fleets ravaged the Italian coasts, and pillaged Nice (1542); but peace was again restored with Germany in 1547. The Turks were now supreme in the Mediterranean; Gozzo and Tripoli fell into their hands, and the conquest of the Banat of Temeswar (1551) assured them a firm hold over Hungary. A second and third war with Persia, which was now in a state of semi-subjugation, the bloodthirsty ambition of his favorite wife Roxolana, who succeeded in persuading him to put to death the children of his other wives, a brilliant naval victory (1561) over the Knights of Malta and their allies the Spaniards, an unsuccessful blockade of Valetta in Malta (1565), and a fresh expedition to Hungary (1566), were the chief events of the remainder of his reign. During this last expedition, while besieging the little town of Szigeth or Szegedin, which resisted all his attacks, he died on the 5th September 1566.

SOMA ('the moon-plant,' or *Asclepias acida*) is, in the Vedic hymns, the god who represents this plant, and one of the most popular deities of the Vedic religion. The reason for this popularity must be sought for in the important part which the juice of the Soma-plant played in the great Vedic sacrifices, and probably also in its alcoholic and invigorating properties, which the sacrificer experienced when he drunk of it in the exercise of his functions. These properties are constantly described or alluded to in the hymns addressed to Sôma. Thus, in some hymns, S. is said to exhilarate Varuṇa, Mitra, Indra, and the other gods who partake of its juice; and in another, the worshipers exclaim: 'We have drunk the Soma; we have become immortal; we have entered into light; we have known the gods. What can an enemy now do to us, or what can the malice of any mortal effect?'

In other passages, the juice of the Soma is said to be a draught of immortality, medicine for the sick, and a remedy for blindness and lameness. Thus S. became endowed with supernatural qualities and divine attributes, and gradually was exalted as one of the most powerful deities. He is the friend, helper, and soul of Indra; he is the slayer of the cloud-demon Vṛ'tra, the destroyer of foes, the dispeller of darkness, the creator of the sun, the upholder of the sky, and the sustainer of the earth, the king of gods and men; he is thousand-eyed, the most heroic of heroes; he is wise, strong, energetic, &c. See the interesting article on S. by John Muir, in his 'Contributions to a Knowledge of the Vedic Theogony and Mythology,' in the *Journal of the Royal Asiatic Society*, new series, vol. i. pp. 135, ff. In the classical period of Hinduism, S. ceases to be worshiped in the character which he has at the Vedic period; he then becomes the god of the moon. This transition from Soma, the plant and its juice, to Soma, the moon, which is perceptible even as early as in the S'atapatha Brâhmana of the White Yajurveda (see VEDA), is apparently due to the belief, that *Amṛ'ta*, the beverage of immortality, was guarded by the moon, and to the circumstance that, in the Vedic hymns, S. is frequently called or described as *Amṛ'ta*. The myths con-

nected with Soma, the moon, are wholly different from those relating to the Vedic Soma. As moon, S. was born from the eyes of Atri, a son of Brahman, the first god of the Trimûrti (q. v.); and became installed by Brahman as the sovereign of plants, Brâhman'as, and planets. But after he had acquired extensive dominion, he became arrogant and licentious, and carried off Târâ (lit., a star), the wife of Vr'ihaspati, the preceptor of the gods. Vr'ihaspati seeking to recover his bride, and some of the gods siding with him, and others with S., a war broke out, which ended in Târâ's being restored to her husband. The result, however, of her stay with S. was the birth of a son named Budha, who became the ancestor of a dynasty of kings, called the lunar dynasty. See SURYA.

SOMA'LI LAND, an extensive maritime country in the east of Africa, is triangular in shape, and is bounded on the N. by the Gulf of Aden, on the S.-E. by the Indian Ocean, and on the S.-W. by the Jub River. From the middle course of the Jub to Cape Guardafui, which forms the apex of the triangle, the distance is nearly 900 miles. The area of the country is estimated at 330,000 sq. m.; but as great part of its interior still remains unexplored, the number of its inhabitants has not been ascertained. The land is elevated and mountainous in the north, and slopes in terraces towards the south. The Jub, which forms the south-west boundary, is a large fertilizing stream, drawing its waters from the mountains of Southern Abyssinia, and flowing south-east between the territories of the Gallas on the west, and those of the Somali on the east, to its mouth on the northern frontier of Zanzibar.

The present Somali race were originally Arabs, who landed on the African shore south of the Gulf of Aden early in the 15th century. Driving back the earlier inhabitants of the country, who were Christians, the Moslem made themselves masters of the country. The inhabitants are extremely violent and quarrelsome in their disposition, are notorious for cheating and lying, and for the most part pursue a wandering, pastoral life. The chief trading-place is Berbera, on the north coast; and the products of the country are sheep, cows, ghee, grass-made mats, ostrich-feathers, and hides. These are exchanged at the ports for cloth, dates, rice, beads and iron.—*What led to the Discovery of the Nile*, by Captain Speke (Edin. 1864).

SOMBRERE'TÉ, a town of Mexico, in the state of Zacatecas, and 90 miles north-west from Zacatecas, in a mountainous district celebrated for its rich silver mines, from which S. derives all its importance. Pop. 14,000.

SOMERSET HERALD. See HERALD.

SOMERSET HOUSE, in the Strand, London, stands on the site of a palace built by the Protector Somerset about 1549, which fell to the crown on Somerset's execution. The original Somerset House was pulled down and rebuilt in 1776, after designs by Sir William Chambers, in the Palladian style. The building accommodates various government and other public offices; the general registers of births, deaths, and marriages are now kept here. The finest front is towards the river.

SOMERSETSHIRE, a maritime county in the south-west of England, is bounded on the N.-W. by the Bristol Channel, and touches Devon, Dorset, Wilts, and Gloucester. Area, 1,049,815 acres. Pop. (1871) 463,483; (1881) 469,010. Its form is oblong, its length being about 80 miles, and breadth about 36. The surface is extremely diversified, there being every variation, from lofty hills and barren moors to rich vales and marshy 'levels,' many thousands of acres of the latter being below high-water mark, and depending for security on sea-banks and sluices. The hills are divided into several ranges running from east to west. One range, known as the Mendips (q. v.), runs from near the city of Wells to the coast at Brean-down. South of these hills is a vast marshy plain, on which the Polden Hills stand out abruptly, like an island. Another conspicuous group, called the Quantocks, rise near Taunton, and attain a maximum elevation of 1270 feet. And finally, in the extreme west, is the wild district of Exmoor Forest, composed almost entirely of barren hills, the highest of which, Dunkery Beacon, is 1668 feet above the sea-level.

The rivers of the county rise chiefly in these high grounds, and are none of them of any magnitude, except the Bristol Avon, which rises in Wiltshire, and for some miles divides S. from Gloucestershire. The Parret drains the middle districts, and is a tidal stream up to Bridgwater, presenting at spring-tides the peculiar phenomenon called the 'bore.' The soil is mostly fertile, and the pasture-lands are almost unrivaled for their luxuriance. The wheat and barley grown around Bridgwater are famous; but grazing and dairy-farming form the great objects of husbandry, and the cheese of Cheddar has a great reputation. Cider is also produced in enormous quantities, but owing to the prevalence of small farms, agriculture is in a backward state. The hilly districts are rich in minerals, especially iron, with some lead and calamine; and the Radstock and Bedminster coal-fields supply the northern districts with excellent fuel. Oolite is largely developed in the neighborhood of Bath, where a beautiful building-stone is extensively produced. The principal manufactures are woollen cloth, coarse linens, lace, silk, and gloves; but these industries are not progressive, and the pop. of S. is diminishing largely in the rural districts.

The medicinal springs are an important feature of the county, having been the means of bringing into celebrity and sustaining the splendor of Bath (q. v.). Weston-super-Mare, containing at the beginning of the century a few hovels, is now one of the finest watering-places on the western coast. S. is divided into three districts for electoral purposes, and returns six members to the House of Commons. The parliamentary boroughs are Bath, Taunton, and Frome—Bridgwater having been recently disfranchised for corrupt practices. In ancient times, this part of the kingdom was inhabited by the *Belgæ*, and the Mendips appear to have formed so strong a barrier against the Roman and Saxon, that, even to this day, philologers can trace the strong Celtic element that held its ground here. British camps are very numerous on the hills; and extensive remains of stone circles are visible at Stanton Drew, near Bristol. In Saxon times, S. was one of the earliest counties to embrace Christianity; and while a church was founded at Wells in 704, on the site now occupied by the fine cathedral, a monastery was founded at Glastonbury, which eventually became one of the wealthiest in the kingdom. S. was the principal arena of the rebellion of the Duke of Monmouth, in 1685.

SOMERVILLE, MRS. MARY, a lady famed for her mastery of mathematics and physical science, was the daughter of Admiral Sir William Fairfax. She was born at Jedburgh on 26th December 1780, and brought up at Burntisland, amid somewhat narrow family circumstances. Her mother taught her to read; but besides this, she had no education till she was nine years old. At ten, she went for a year to a school at Musselburgh; and on her return, took more delight in reading whatever came in her way than in sewing, to the great discomfort of her relatives. After she was thirteen, she twice had, during a sojourn in Edinburgh, an opportunity of attending classes, studying music, drawing, and a little Latin, and of mixing with Edinburgh society. It is somewhat singular that it was in an algebraic sum in a magazine of fashions that Mrs. S. first made her acquaintance with the subject that most engrossed her attention later in life. In 1804, she married Mr. Greig, a commissioner in the Russian navy, and removed to London. Although Mr. Greig did not prevent her from continuing her studies, he himself had no interest in science, and had the usual prejudices against learned women. It was not till her return north as a widow, after three years of married life, that she was free to buy the books she wanted, and to study the subject that most interested her. She was now 33 years old, with two children.

In 1812, she married her cousin, Dr. William Somerville, who entered warmly into all her ideas. Her husband and she removed to London in 1816, where Mrs. S. went much into society, and became known as possessed of scientific interests and gifts. In 1823, Mrs. S. was invited by Lord Brougham to try to popularize, for the English public, Laplace's great work, the *Mécanique Céleste*. This she was persuaded to undertake, and published it as the *Celestial Mechanism of the Heavens*, in 1830. The work was received with the greatest admiration. Mrs. S. was awarded a royal pension in 1855. *The Connection of the Physical Sciences* was published in 1835, and has passed through nine editions. Her next work was *Physical Geography* (1848), of which there have been six English editions. *Molecular and Microscopic Science* appeared in 1866. Mrs. S., who for many years resided in Italy, died at Naples, 29th Nov. 1872, having maintained till the end the perfect use of her faculties. An autobiography, edited and supplemented by a daughter of Mrs. S., was published in 1873.

SOMERVILLE, a city of Massachusetts, U. S., 2 miles north-west of Boston. Many of its inhabitants are business men from Boston; but it has some manufactures, bricks, leather, iron, carriages, and glass. Pop. (1870) 14,685; (1880) 24,985.

SO'MMA, a town of Southern Italy, at the northern base of Mount Vesuvius. Pop. 7400.

SOMME (anc. *Samara*), a river of Northern France, rises in the dep. of Aisne, and falls into the English Channel. Its entire length is about 120 miles, of which one-half is navigable.

SOMME, a maritime dep. in the north of France, south of Pas-de-Calais, and north-east of Seine-Inférieure. It has an area of 2377 sq. m., and a pop. (1881) of 550,837. S. is for the most part quite level, and in some parts marshy. The dep. produces abundance of corn and fruits; cattle are reared; and there are manufactures.

SOMNAMBULISM (Lat. sleep-walking). Walking in sleep is the most palpable, but not the most marvelous characteristic of this condition. The person affected walks, rides, climbs, with the eyes shut or insensible; his movements are precise, cautious,

leading him into positions of difficulty and peril, which, if perfectly alive to their real nature, or if acting under the influence of ordinary motives, he would avoid; and yet there appears to be a partial consciousness of surrounding objects, and an adaptation to circumstances. Individuals have, while in this state, performed long journeys on foot or horseback, paying tolls, avoiding obstacles; they have successfully descended into coal-mines; they have ascended in safety to the roofs of houses, have climbed rocky cliffs, and successfully robbed eagles' nests, during the night; millers, saddlers, grooms, seamstresses, have all performed their customary work with perfect exactitude, but without any recollection of their exertions or industry. Notwithstanding the accuracy with which many acts are performed, that particular senses may be dormant is proved by insensibility to loud noises, and by a cook eating cabbage which had been substituted for a salad which he had carefully and artistically prepared. The senses, in relation to the idea or train of ideas present to the mind, appear to be awake, and preternaturally acute.

This fact has suggested the hypothesis, that certain faculties are wakeful, open to impressions, and actuated by volition; while others, and the mind in general, are plunged in profound sleep and unconsciousness. This may be true, and is in harmony with the opinion, that the phenomena are an acted dream or delusion, and that what is seen, heard, or done, is the mere embodiment or repetition of former impressions or impulses, at the time before the mind. This may be illustrated by the case of the student narrated by the Archbishop of Bordeaux, who composed a sermon and wrote out music while asleep; read them over, made corrections, scratched out lines, substituted others, put in its place a word that had been omitted, and continued to do all this, although a sheet of pasteboard was interposed between the writing and his face; showing that he was copying mental images, and not with the eye.

Somnambulism occurs in the sensitive and excitable, often in conjunction with other nervous affections, and is hereditary; so that it may be regarded as on, if not within, the boundary of disease.—Macnish, *Philosophy of Sleep;* Binns on *Sleep.* See also the article ANIMAL MAGNETISM, and the works there referred to.

SOMNAU'TH, or SOMNATH-PUTTEN, a town of Guzerat, in Hindustan, is situated on the south-west coast of the peninsula of Kattywar (q. v.), about 33 miles from its southern extremity, and has at present a pop. of 5000, most of whom are Mohammedans. The town is fortified by a strong stone wall 9 feet thick, strengthened by 38 towers; it contains many mosques, and the ruins of the celebrated Hindu temple of the idol Somnauth. The ruins of the temple are in a state of fair preservation, and give the idea of its having been a gloomy, massive temple in the form of an oblong hall 96 feet by 68 feet, crowned by a magnificent dome, and covered on the inside and outside with elaborate sculpture and carving illustrative of mythological subjects. The splendor of this temple has doubtless been much exaggerated by various travelers; but a thousand years ago it was so famous as a place of pilgrimage for pious Hindus, as well as for its immense wealth—the accumulations of centuries of presents—that it attracted the zealous idol-destroyer, Mahmud of Ghizni, after he had accomplished his self-imposed mission of conquest, spoliation, and conversion in the rest of Northern India. In 1024, he appeared before S., drove its defenders—who at first had been buoyed up with sanguine hopes that their favorite god had drawn the Mohammedans hither that he might blast them with his wrath—to take refuge in the temple, where they defended themselves with such valor, that Mahmud's army was forced to retreat; but the subsequent rout of two Hindu armies which had advanced to the aid of the sacred city, so dispirited the defenders, that S. was immediately surrendered, the idol destroyed, and the enormous wealth of the temple, consisting chiefly of precious jewels, carried off, along with the gates of the temple.

These gates, which are said to have been made of sandal-wood, were brought back from the entrance to Mahmud's tomb in Afghanistan by the British in 1842, and their recovery announced in a magnificent proclamation, which called upon the chiefs of Sirhind, Rajputana, Malwa, Guzerat, to transmit them 'with all honor' to the place whence, eight centuries ago, they had been violently removed. They were, however, never restored to S., as the home authorities disapproved of the tenor of the proclamation, fearing that it might stimulate religious animosity betwen the two great religious bodies of Hindustan. There was also reasonable ground of doubt as to whether the gates were really the original gates of S., and even whether (since the *Ferishta* does not mention the circumstance) Mahmud had taken away any gates. The repute of S. as a place of religious pilgrimage, and its wealth, revived some time after its spoliation by Sultan Mahmud, to such an extent as frequently to attract the various Mohammedan robber-princes of Western India; and it is still at the present day a chief resort of pious Hindus from all quarters, who pay a small tribute to the Guicowar for liberty to perform their devotions at this favorite shrine.—See Price's *Mohammedan History*, vol. ii.; Dow's translation of the *Ferishta*; Mirkhond's *Rauzat-al-safa;* Sir John Malcolm's *History of Persia*, vol. i.; and Smith's *Life of Dr. John Wilson* (1878).

SONA'TA, a musical composition for a solo instrument, sometimes accompanied by one or two other instruments, consisting of three, four, or even more movements; these movements usually consist of a subject or subjects, given out first in the key of the dominant, and after certain episodes, in which these themes are presented in a great variety of aspect, they are repeated in the key of the tonic. This form is in general most closely adhered to in the first movement of a sonata, and exhibits great room for a display of the inventiveness and musical resources of the composer. The second movement is generally slower and shorter than the rest, and often in the form of a theme with variations. The most important compositions of this kind are for the pianoforte, many of which have been written by Haydn, Mozart, Beethoven, Clementi, Dussek, and other masters.—A short sonata with two or at most three movements, less elaborately worked, is called a *Sonatina.*

SO'NCHUS. See SOW THISTLE.

SO'NDERSHAUSEN, the chief town of the principality of Schwarzburg-Sondershausen, pleasantly situated on the Wipper, 36 miles north-west of Weimar. Pop. (1880) 6110.

SONG, a short poem adapted to vocal melody. The word is generally applied to the poetical and musical composition in union, but sometimes to one or other separately. The poem generally turns on some single thought or feeling, and is divided into portions of returning measure. The term song, properly implying an air of a simple kind, is often, though not very correctly, applied to the elaborate *aria* of the opera, or the solemn air of the oratorio. A song generally implies an air for a single voice—airs for more than one voice being, however, sometimes called part-songs. England produced in the course of last century a large number of beautiful songs. Of the numerous songs which are continually appearing in this country at the present day, extremely few have musically much merit, and in a large proportion of cases the words are of a silly and insipid description. Germany has of late produced a larger proportion of beautiful songs than any other country. Amongst songs, not the least interesting are the national and popular airs of different countries, generally of uncertain date, and almost always possessed of much character.

SONG OF BIRDS. All birds have some voice or cry which they utter, and some of them various notes appropriate to various occasions. The power of producing clear and sweet musical notes is chiefly found in certain families of the order *Insessores;* some of which, as the lark, pour forth their song in the air; but the greater number, like the thrush and nightingale, sit whilst they sing. The compass and variety of notes, the power of trilling and shaking, the loudness, clearness, and sweetness of the song, differ very much in different species, each of which may be as perfectly recognized by its song as by its form or plumage. There are also, as is well known, great differences among individuals of the same species, and Mr. Jesse asserts his confidence that there are notable differences between the song of the birds of the same species generally in one district and in another, just as there are provincial dialects and modes of pronunciation in human speech. 'The song, for example, of a thrush near London, or in any of the home counties, has little resemblance, except in specific character, to that of the same bird in Devonshire or near Exeter. The same notes, I suppose, will all of them be detected, but they are arranged for the most part into a different tune, and are not sung in the same way. They are given with different values, and the singing is pitched in a different key.'

The singing of birds is chiefly connected with the love-season; although some birds sing at other seasons also, during fine weather, and when food is abundant, as if merely to utter their happiness, and by uttering, to increase it. It is during the pairing-time that they are most vocal; the singing of many is continued with frequency also during the period of incubation, but with some change of character, exhibited in a marked degree by the chaffinch. The male alone sings. Female birds have voice also, but cannot warble like their mates. The song of birds is not produced by the larynx proper, but by the *syrinx* or lower larynx, a distinct organ.

There can be no doubt that the singing of the male bird is intended to attract and please the female, and that he delights in this display of his own powers. In this respect there is no difference between the birds of most melodious song and those of harsh discordant voice. In them may be also seen an emulation which is ready further to display itself in combats. But questions of rivalry seem in part to be decided amongst some of the songsters of the groves by mere musical displays. The song of birds is accordingly made to play an important part in the theory of evolution by natural selection. Caged birds evidently often sing from emulation.

The imitative powers so remarkably possessed by the mocking-bird and a few other species, are to some extent possessed by many birds. It is said that canaries may be taught to sing a complete tune from a musical box, adjusted to play one tune only.

SONGHAY, a former kingdom of Africa, extended both east and west of the river Niger below its great bend. Its king embraced Islam in the 11th century. In 1468, the ruler of S. conquered Timbuktu and the surrounding state. Under Háj Mohammed Askia, at the end of the 15 c., the S. empire extended from Hausa almost to the shores of the Atlantic, and from lat. 12° N. to the confines of Morocco. After many years of civil war, this great empire became a province of Morocco in 1607. It is now partly independent. Gagho, its capital, was at the time of Barth's journey a mere village. S. is also spelled *Sonrhai*.

SONNET, a poem which expresses one idea, mood, or sentiment, and usually extends to fourteen decasyllabic lines, with a somewhat intricate arrangement of rhymes. It is admittedly one of the most refined and intellectual forms of poetic expression. Every sonnet should be full and complete, though terse; and be firmly but gracefully rounded off. The oldest extant specimens of the sonnet are those of Vernaccia, of the 12th, and Peter delle Vigne, who lived in the 13th c.; but it received its highest finish at the hands of Dante and Petrarch. Early in the 16th c , Sir Thomas Wyatt and the Earl of Surrey introduced the sonnet into English literature, and Sidney, Spencer, Shakspeare, Daniel, Drayton, Drummond, extended its use and scope. In the early Italian models, the first eight lines make two quatrains, and the remaining six, two tercets. The quatrains have two rhymes, usually arranged so that the 1st, 4th, 5th, and 8th lines rhyme, as also 2d, 3d, 6th, and 7th. In the tercets great liberty is allowed; but there are generally three rhymes, and they are never arranged in couplets.

There is no Italian precedent for the freedom taken by the English poets before Milton, including Spenser and Shakspeare, of making the sonnet simply a poem of three quatrains, with alternate rhymes, and a rhyming couplet (the common 'illegitimate' form). Some writers call a poem of several pairs of rhyming couplets a sonnet, and there are also so-called sonnets of thirteen or fewer lines. Most of Milton's sonnets are a close approach to the true Italian type. Gray, Warton, and Bowles revived this form of poetry, and Wordsworth contributed about four hundred sonnets to our literature. Coleridge, his son Hartley, Keats, Shelley, Procter, Mrs. Browning, C. (Tennyson) Turner, Sidney Dobell, and D. G. Rossetti, are known as sonnet writers. See *The Sonnet*, by Tomlinson (1874), and the notes in the collections named below. Anthologies of the sonnet are numerous: Henderson's *Petrarcha* (1803); Capel Lofft's *Laura*, 5 vols. (1814), in six languages; and collections of English sonnets by Dyce (1833); Lees (1867); Dennis (1873); Main (1880); Waddington (1880–82); and Caine (1882).

SONNINI DE MANONCOURT, Charles Nicolas Sigisbert, an eminent French traveler and naturalist, born in 1751. Besides a residence for some years at Cayenne, he traveled in Egypt, Greece, the Archipelago, and Asia Minor. He made many valuable researches in natural history, and published several works, the chief being *Voyage dans la Haute et dans la Basse Egypte* (1799), and *Voyage en Grèce et en Turquie* (1801). S. died at Paris in 1812.

SON OF GOD. Considered from the side of dogmatic theology, the phrase Son of God denotes the Second Person of the Trinity (q. v.). If we examine the use of the name in the Scriptures, we find it to have been applied by Jesus to himself, and given to him by his disciples, to express the mysterious relationship in which he stood to God. The phrase was one not altogether unknown to the Jews. The plural 'sons of God,' occurs several times in the Old Testament; in some cases it is applied (tropically) to angels, in others to the children of Israel, and in their collective capacity as the favored nation, they are twice called by God his 'son' (Ex. iv. 22, 23; Hosea xi. 1). The use made in the New Testament of the famous passage of the 2d Psalm ('Thou art my Son; this day have I begotten thee') is thought by some to constitute conclusive evidence that the spiritually-minded among the ancient people recognized a 'Son of God.' It has been argued, however, that if the Hebrews generally, or even their spiritual leaders, had believed the Messiah to be the 'Son of God' in any other sense than that he was prophetically filled with the Spirit of God, both the idea and the phrase would have played a far more prominent part than they do in the religion and literature of the nation. Nor does it appear that the idea of a 'Son of God' (in the divine sense) had rooted itself in the Hebrew mind. Hence, we find that the assumption of the title by Jesus provoked the bitterest opposition on the part of the great majority of his countrymen.

They did not hate him because he claimed to be the 'Messiah,' the 'Christ;' on the contrary, they were prepared to accept as such any teacher whose words or works might seem to them to justify his pretensions to the dignity; but when Jesus claimed to be the 'Son of God,' equal and one with the Father, they sought to stone him. It was, in fact, this assertion of his divinity that cost Jesus his life.

SONO'RA, a frontier state in the north-west of Mexico, bounded on the N. by the United States' territory of Arizona, and on the W. by Lower California and the Gulf of California. Area, 83,404 sq. m.; pop. (in 1873) 109,388. Several fine bays indent the coast; lagoons occur near the shore; and in the western part of the state there are several lakes. The great system of the Andes skirts the eastern frontier, and throws off branches which occupy much of the surface of the state. In the west, the surface is mostly flat, with a fertile soil, and a warm but variable climate. The chief rivers are the Rio Colorado, Sonora, Yaqui, and Mayo. Two abundant crops are gathered every year from the same land; and the principal crops are wheat, maize, peas, and beans; though tobacco, sugar-cane, and cotton are also grown. But the wealth of the state is not in its agricultural capabilities, but in its mineral treasures, which are considered inexhaustible, especially gold and silver. Cattle rearing is extensively carried on.

SONSONA'TÉ, a town of Central America, in San Salvador, and 40 miles west-north-west of the city of that name. Pop. about 10,000 inhabitants.

SONTAG, Henrietta, an eminent German vocalist, was born in 1806, and educated for the stage. After a brilliant operatic career at Vienna, Berlin, Paris, and London, she married Count Rossi in 1829, and left the stage in 1830. Compelled by pecuniary difficulties to reappear in 1849, she met with renewed success both in Europe and America. She died in Mexico in 1854.

SOO-CHOW, or SU-TCHOU, or SOO-CHOW-FOU (*fou* merely signifying *city*), a large city of China, in the province of Kiang-su, 60 miles west-north-west from Shanghai. It stands near the Grand Canal which connects Hang-chow with Nanking and Pekin, but its port is Shanghai, with which also it has water-communication. It is about ten miles in circumference, and is enclosed by fortifications, outside of which are four very large suburbs. The country around S. is level, and remarkable for its fertility, so that the Chinese speak of it as a terrestrial paradise. The city has silk manufactures, printing establishments, and a large trade in books. In 1857, S. was captured and sacked by the Taepings. In 1863, it was invested by the Imperialists, under a British officer, and the rebel chiefs having surrendered, were treacherously beheaded by the governor of the province.

SOOLOO' ISLANDS. See Sulu Islands.

SOO'SOO (*Platanista Gangeticus* or *Soosoo, Gangeticus*), a cetacean of the Dolphin family, inhabiting the Ganges, and most abundant in the sluggish waters of its delta, but found also as far up the river as it is navigable. It is supposed to be the *Platanista*

Soosoo (*Platanista Gangeticus*).

of Pliny. It is the only known existing species of its genus, and is interesting as a fresh-water cetacean. It attains the length of about 12 feet, and is not unlike the dolphins in its general form. The habits of the S. are sluggish, except that in pursuit of prey it moves with great energy and rapidity. The flesh resembles lean beef, but is never eaten by the Hindus who, however, set a great value on the fat, which lies between the skin and the flesh, as an external medicinal application. There are several fossil species of this genus.

SOOT is that portion of fuel which escapes combustion, and which is mechanically carried up by the current of hot air, either to be deposited on the sides of the chimney, or to be discharged into the atmosphere. The soot of coal and that of wood in all probability differ materially, the former containing more carbonaceous matter and more ammoniacal salts than the latter. Braconnet published an elaborate analysis of the soot of wood; but good recent analyses of both kinds of soot are still required. Both kinds are used as manure; and wood-soot, under the title *Fuligo Ligni*, was formerly contained in the British Pharmacopœias. According to Neligan, it has been found most efficacious in the latter stages of hooping-cough in children, and in some forms of hysteria; and he gives directions for the preparation of a Decoction, an Extract, a Spirit, and a Tincture. See Neligan's *Medi-*

cines, &c. (6th ed., p. 53). Contact with soot often gives rise to a peculiar form of cancer, which is consequently known as *Chimney-Sweepers' Cancer*.

SOPHI'A, a town of Bulgaria, 170 miles north-west of Adrianople, in a beautiful plain on the river Isker. Besides about 30 mosques, it contains several Christian churches, is the see of a Greek and a Roman Catholic archbishop, and carries on manufactures of cloth, leather, silk goods, and tobacco. Its hot springs and baths are highly esteemed. Pop. 24,000. S. occupies the site of the ancient Sardica.

SOPHIA, St., Church and Mosque of, a celebrated structure at Constantinople, long an object of great interest to all visitors of that city. It was originally built by the Emperor Constantine in 325—326, on occasion of the translation of the seat of empire to Byzantium; and is so called as being dedicated, not, as commonly supposed, to a saint of that name, but to the *Hagia Sophia* (Holy Wisdom), that is, to the Eternal Wisdom of God or the Logos, the Second Person of the Trinity. The building of Constantine was subsequently rebuilt and enlarged by his son Constantius; and this second church of Constantius having been destroyed in 404, was rebuilt by Theodosius the Younger in 415; and it lasted unaltered till the celebrated Nika Sedition, or Battle of the Factions of the Circus, under Justinian, in 532, in which it was totally destroyed. The present building is substantially that which was erected by Justinian in expiation of this sacrilege. It occupied less than seven years in its erection, and the history of the work and of the details of its material and construction are full of marvels. Ten thousand workmen are said to have been employed upon it. The materials were supplied from every part of the empire, and comprised remains of almost every celebrated temple of the ancient paganism. The sedilia of the priests and those of the patriarch were of silver gilt. The dome of the tabernacle was of pure gold, and was surmounted by a gold cross weighing 75 lbs., and encrusted with precious stones. All the sacred vessels and other apparatus were of gold.

The altar-cloths were embroidered with gold and pearls; and the altar itself was composed of a mass of molten gold, into which were thrown pearls, sapphires, diamonds, onyxes, and every other object which could raise its costliness to the highest imaginable degree. The total cost of the structure is stated by the ancient authorities at 320,000 *pounds*. Some regard this as pounds-weight of silver, others as of gold. One of the latest writers on the subject, Mr. Neale (*Eastern Church*, vol. i. p. 237), adopts the latter estimate, and thus computes the cost at the enormous sum of £13,000,000!

The building may be described as a square of 241 feet, forming interiorly a Greek cross, and surrounded in the interior by a woman's choir or gallery, supported by magnificient pillars, for the most part borrowed from ancient buildings. In the center rises a dome, which is supported by two great semi-domes, which in their turn rest upon smaller semi-domes, the whole presenting a series of unexampled beauty. The height of the dome is 175 feet. The building is approached by a double porch, which is about 100 feet in depth. The whole of the interior was richly decorated with sculptured marble and mosaics. Even in the reign of Justinian, a further reconstruction of the building became necessary, the dome having fallen in, on an earthquake; but this may be said to have been the last important change in the structure within the Christian period of Constantinople.

On the occupation of that city by the Turks in 1453, St. S. was appropriated as a mosque. All its purely Christian fittings and internal structures were swept away. The Christian emblems were either mutilated or covered up from view by a coating of plaster. The latter course was adopted throughout the building in the case of mosaic pictures containing representations of the human figure, which the Koran proscribes as unlawful, and thus the original mosaics of the Justinian era have in great part escaped destruction. About the middle of this century, the sultan Abdul Medjid having ordered a complete restoration of the building, these mosaics were accidentally brought to light, and, with the consent of the sultan, artists were sent out from Berlin, who, with the assistance of the architect employed by the Turkish government, made accurate copies of all these interesting relics of antiquity, which have been published at the expense of the Prussian government by Salzenburg, the artist thus employed by the king. The interior of the building at present is very judiciously restored for Mohammedan worship, the Christian decorations being again carefully covered up, coated with plaster in imitation of mosaic-work. Like all mosques, St. S. is closed against Christian visitors except upon special firman, which, however, is easily obtained. The weight of the dome has more than once threatened to crush in the substructure, rendering repairs necessary.—See Von Hammer's *Constantinopolis* (1882); Salzenburg's *Alt-Christliche Baudenkmale Konstantinopels* (1854); Hughes, *Aya Sofia Constantinople* (London, 1854); De Amicis, *Constantinople* (transl. from 7th Italian edition); W. Besant, *Constantinople* (1879).

SO'PHISTS. The Sophists were the leading public teachers in ancient Greece during the 5th and 4th centuries B.C., and their character has been a subject of much dispute. Most of the historians of philosophy—influenced seemingly by the lampoons of Aristophanes, the comic poet, and by the disparaging remarks of Socrates, Plato, and Aristotle, who stood in a quite different position from the teachers by profession—represent the Sophists as 'ostentatious impostors, flattering and duping the rich youth for their own personal gain, undermining the morality of Athens, public and private, and encouraging their pupils to unscrupulous ambition and cupidity.' Mr. Grote, in his *History of Greece*, chap. lxvii., has combated these positions, and given a much more favorable view of the Sophists.

A Sophist, in the original sense of the word (derived from *sophos*, wise or learned), was a wise man, a clever man, one who stood prominently before the public for intellect or talent. Solon and Pythagoras are called Sophists; the name was applied even to great poets. Socrates was repeatedly so designated; Plato is alluded to by the same title. By the general public, any man of intellectual eminence would be spoken of as a Sophist. With the feeling of admiration towards the intellectual class, there was mixed up a certain invidious sentiment, from whatever cause arising; and the name Sophist being often used to express the dislike as well as the admiration, came ultimately to have a predominating bad sense. Still the general public, in the use of the word, comprehended Socrates, Plato, and Aristotle, and their philosophical disciples and followers, equally with the professional teachers.

The great intellectual start made in Greece during the 5th c. B.C., led to an advanced standard of general instruction. There had been an established popular education long before—including music, reading, and recitation—but now there were found among the public teachers men of the highest accomplishments that the age could furnish, who taught whatever was known of astronomy, geography, and physics, as well as the newly started controversial discussions in ethics and in metaphysics. These men shared with the other intellectual celebrities the title of Sophist. But there was one circumstance in their case that greatly deepened the invidious sentiment—they taught for pay. This brought them under the odium of two classes; in the first place, the poor, who could not afford the fees, felt themselves in a new position of inequality with the rich; secondly, the philosophers, properly so called, who had not yet begun to receive money from their disciples, held in contempt those that did. Both Socrates and Plato had a vehement repugnance to the idea of a money-bargain between master and pupil; in their eyes, the relationship was one of pure attachment and devotion; and they considered that all the invidious part of the designation Sophist, and more, was richly deserved by the teachers for hire; and as these public teachers, by the nature of their vocation, would probably be often shallow and superficial, as compared with the great philosophers, we can understand the full definition of Sophist by Aristotle—'an impostrous pretender to knowledge, a man who employs what he knows to be fallacy, for the purpose of deceit and of getting money.'

With all the great authority of Aristotle, this charge applied indiscriminately to the body of men employed in training youth for active life, will not bear investigation. Enough is known of the lives, characters, and doctrines of the class to refute the accusation. The Sophists were a profession growing out of the circumstances, and supplying a want, of the age. The most valuable ideas and habits of any accomplished Athenian were due to his education under some teacher of the class Rhetor or Sophist. So far from the age of the Sophists being an age of corrupted public morality, Mr. Grote contends that it was the reverse. He adduces a multitude of historical facts to prove that the morality of the Athenian public was greatly improved at the end of the 5th c. B.C., as compared with the beginning of that century.

SO'PHOCLES, the great master of Greek tragedy, was born at Colonus, a village about a mile from Athens. The date of his birth is not exactly known, but is fixed at 495 B.C. Sophillus, his father, a man of good birth and fortune, bestowed much care on his son's education; insomuch that, aided by his highly prepossessing appearance, S. was selected for his skill in poetry and music to lead with dance and the lyre, after the victory of Salamis, the chorus of youths in a triumphal pæan composed by himself. In his 28th year, he is said to have *exhibited* his first play; and three years before, in a contest with rival scenic writers, one of whom was Æschylus, he gained the first prize, by the decision of the judges Cimon and his colleagues. He had, by Nicostrata, two sons, and one by Theoris, a Sicyonian woman.

Iophon, one of his two sons by Nicostrata, summoned him in his old age before the Phratores, on the charge of incapacity to manage his private affairs, but he refuted the charge by reciting to the court a beautiful chorus from his *Œdipus in Colonus*. He died at the age of 90, full of years and honors. His private char-

acter was easy and contented, but not, as has been hastily assumed, profligate. His turn of mind was devout, as is evident throughout his plays; and he evinced no taste for political or active life, although he is said to have accepted command in the Samian war. He was a prolific author. He was the reputed composer of as many as 130 plays, of which, however, 17 have been deemed spurious. He gained, according to his biographer, the first tragic prize 20 times, bearing the palm on several occasions from Æschylus and Euripides, not to mention less well-known competitors. He wrote also pæans, elegies, and epigrams, of which we have but few remains. He lived on terms of intimacy not only with his great rivals, but with Aristophanes and Herodotus. We have no knowledge of the order in which his plays, that have survived, were written. The most plausible arrangement is perhaps that of Müller, who graduates them as follows: *Antigone, Electra, Trachiniæ, Œdipus, Rex, Ajax, Philoctetes, Œdipus Coloneus.*

S. is justly accounted the most perfect of the Attic tragedians. In his hands, tragedy becomes the true and faithful reflex of human feelings, passions, impulses. His ideas are ethical, with a constant reference to a divine disposer of events. 'There has hardly,' says Müller, 'been any poet whose works can be compared with those of Sophocles for the universality and durability of their moral significance. Of all the poets of antiquity, he has penetrated most deeply into the human heart.' His versification is remarkable for its softness and fluency. The best editions are those of Wunder (1831—1846), Schneidewin, and Campbell (1874—1882). The chief translations of S. into English are those of Potter (Lond. 1788), Dale (Lond. 1824), and Plumptre (1865.) We may also mention special translations by Prof. Thompson of the *Ajax*, by Dr. Donaldson of the *Antigone*, and by Prof. Campbell of the *Antigone, Electra*, and *Dejanira.*

SOPRA'NO (Ital.), the highest species of female voice, whose range extends from to , or in some cases higher.

The highest notes generally belong to the falsetto register. Sweetness and mellowness are the characteristic qualities of a soprano voice, which is for the most part less full than an alto, but lighter, fresher, and more expressive of joyful, lively, and highly impassioned feelings. Music for soprano voices is usually written in the treble clef, but sometimes in the soprano clef with C on the first line . A voice sometimes distinguished as intermediate between alto and soprano, is the *Mezzo-soprano*, whose usual compass is from to .

SO'RA, a city of Southern Italy, in the province of Caserta, with (1871) 5100 inhabitants. It stands in a fertile plain, watered on one side by the Liris or Garigliano, which is spanned by two bridges at the town. The population is industrious and wealthy. There are manufactories of woollen cloth and of paper. S. was originally a Volscian town, passed into the possession of the Samnites, and then into that of the Romans. Remains of the cyclopean walls of the ancient citadel are still visible.

SO'RAU, a town of Prussia, in the province of Brandenburg, 60 miles south-south-east of Frankfurt-on-the-Oder. It has important bleach-fields, print-works, and color-works. Pop. (1875) 13,-191. S. is one of the oldest towns in Prussia.

SORB. See SERVICE.

SORBONNE, a celebrated academic body at Paris, which dates from the middle of the 13th c., and which, down to the French Revolution, held a prominent place in all church controversies. It derives its name from its founder, Robert de Sorbon, a canon of Cambrai, born at Sorbon, in the Ardennes, in 1201. He was selected by Louis IX. as his chaplain and confessor. At this time, the university of Paris was at the very height of its celebrity, and Robert de Sorbon resolved on opening in it an institution in which a society of secular priests, being provided with all the necessaries for their own maintenance, should devote themselves gratuitously to the teaching of theology. It was established with the sanction of King (afterwards St.) Louis in 1252, originally for the reception of sixteen scholars, four respectively from the Gaulish, Norman, Picard, and English nations, to which the German was subsequently added.

Robert was himself the first head; and in 1270, drew up its constitution, which remained in force without any substantial alteration till the French Revolution. It was not confined to the original poor scholars, but extended to the bachelors and doctors aggregated to the body of the Sorbonne. All these were of necessity graduates of the Faculty of Theology of the university of Paris, but they were only admitted to membership of the Sorbonne by the votes of that body which formed one of the four constituent parts of the Theological Faculty; and after a public disputation, technically called the 'Sorbonica,' or 'Robertina,' in which the disputant was required to sustain, against all antagonists, from the hour of five in the morning to that of seven in the afternoon, theses or propositions selected from the whole range of theological science. The first disputant was a Franciscan friar named Mayron, a scholar of John Duns Scotus; but he was followed by many of the greatest names in medieval and post-reformation history. These 'Sorbonne Acts' form in some respects one of the most characteristic chapters in medieval literary history. The disputants in some cases exceeded sixty in number. The foundation of Robert de Sorbon was approved in 1268 by Clement IV.; but the name of Sorbonne does not appear to have been appropriated to it till the 14th century. Robert de Sorbon also established another preparatory college for the study of the Humanities and Philosophy, which was called the college of Calvi, or the Little Sorbonne.

In the 15th c., the Sorbonne, as being in great measure identified with the Theological Faculty of the Paris University, holds an important place in the history of theological controversy, and in all the contests which followed the Reformation in France; there being few of the great names of the Gallican Church which are not included in its academic roll. Among the munificent works of the great Cardinal Richelieu, who was a pupil of the Sorbonne, was what may be described as a complete reconstruction of the buildings. The new Sorbonne comprised, in addition to the public academical hall, lodgings for the 36 doctors, which were assigned to the doctors successively in the order of seniority. The head of the Sorbonne institute was called Provisor, and was elected by the members, together with the Archdeacon of Paris, the four Deans of Faculty, and some other dignitaries of the university. Besides the resident members of the Sorbonne, there were also external associates, called 'Socii Hospitalitatis,' who had no share in the governmental acts of the institution. The Sorbonne continued in the enjoyment of its privileges and its revenues down to the Revolution, when it shared in the common ruin of all the ecclesiastical establishments of France. At the reorganization of the university by Napoleon in 1808, the Sorbonne was re-established as the Theological Faculty of that body; but it failed to recover its old prestige even with the clerical body. One of the conditions of membership was an oath to maintain the celebrated four 'Gallican Propositions.' See GALLICAN CHURCH. This condition deterred many; and although it was revoked by the proposed concordat of 1817, yet, on the failure of this concordat, it still continued in force down to the revolution of 1830.

After various changes, the Sorbonne is still an important theological school, with seven professors and a dean. These professors, however, are named by the Minister of Public Instruction; and the absence of control on the part of the bishops over their appointment and their teaching, has le to the general withdrawal of clerical students from their lectures. Nevertheless, the Sorbonne still possesses at least the permissive sanction of the church. But the Sorbonne is now further the seat of two other faculties of the Académie of Paris (i. e., University of Paris, see UNIVERSITY OF FRANCE), those of Letters and Sciences; there being 12 chairs in the former faculty, and 7 in the latter. (The other two of the five faculties, jurisprudence and medicine, are accommodated elsewhere). All the lectures are open to the public (except ladies) gratis, and are attended by but few regular students.

SORE'CIDÆ, a family of Mammalia, of the order *Carnaria*, and section *Insectivora* of Cuvier. They are generally small animals, covered with soft hair; under which, on each flank, is a band of stiff closely-set bristles, and among them glands which exude a peculiar odorous fluid. The legs are short, and the feet are five-toed, and generally formed for burrowing. Some species are aquatic, and their feet webbed. The S. are all plantigrade. Most of them are nocturnal animals. They generally feed on insects and worms. A remarkable characteristic of the family is the elongated muzzle. They have long incisors, and their molar teeth are generally furnished with conical points. The tail is generally scaly. To this family belong Shrews, Shrew-mice, Musk Rats or Desmans, &c. They are found both in warm and cold climates. Those which inhabit cold climates generally pass the winter in a lethargic or dormant state.

SORESI'NA, a mercantile town of Northern Italy, province of Cremona, with (1871) 8553 inhabitants. A great trade is carried on in a kind of condiment called *Mostarda*, which is prepared there, consisting of fruits, &c., preserved in vinegar and sugar, and also in a kind of liqueur called *Mistrà*, held in great repute in Italy as a carminative.

SO'RGHO GRASS AND SORGHUM. See DURRA.

SO'RIA. See NUMANTIA.

SOROCA'BA, a town of Brazil, in the province of Sao Paulo, stands on a river of the same name, 70 miles west of the city of Sao Paulo. Pop. 12,000.

SO'RREL (*Rumex*), a genus of plants of the natural order *Polygoneæ*, very closely allied to *Polygonum* (q. v.) and *Fagopyrum* (see BUCKWHEAT), but having the perianth divided into six segments, the three inner of which enlarge and cover the *achenium*. The genus is very naturally divided into two sections, the first of which is already noticed in the article DOCK. The name S. belongs only to the second, characterized by dicœcious flowers, and acidity of stems and leaves. COMMON S. (*R. acetosa*) is a perennial found in meadows and pastures throughout the whole of Europe, and is very plentiful in Britain. Its stem is from a foot to two feet high; its leaves arrow-shaped. It is an agreeable salad, and is used in soups and sauces, and as an addition to dishes of greens. It is therefore sometimes cultivated in gardens.—FRENCH S., or ROMAN S. (*R. scutatus*), a native of France and Italy, has broader and blunter leaves, and is more frequently cultivated than Common S., being considered of finer flavor. SHEEP'S S. (*R. acetosella*) is a very similar plant, but of much smaller size, and its roots run very much under-ground, so that it is a very troublesome weed in gardens and fields of poor dry soil, in which it is very common in all parts of Britain.—For WOOD S., see OXALIDEÆ.—For the RED S. of the West Indies, see HIBISCUS.

SORREL TREE (*Lyonia arborea*, formerly *Andromeda arborea*), a tree of the natural order *Ericeæ*, remarkable in that portion of the order to which it belongs for its magnitude, its near allies being generally small shrubs. It grows chiefly on the Alleghany Mountains, from Virginia to Georgia, and attains the height of 50 feet, with a trunk 12—15 inches in diameter. The wood is of little or no use. The leaves are acid, and are sometimes used for dyeing wool black.

SORRE'NTO (Lat. *Surrentum*. Gr. *Syrentum*), a maritime town in the south of Italy, province of Naples, is situated on the south-east side of the beautiful Bay of Naples, on the promontory which separates the latter from the Gulf of Salerno, about 7 miles south-west of Castellamare. Pop. (1871) 5502. It is an archiepiscopal see, and possesses a cathedral. The manufacture of silk is extensively carried on. There are still considerable remains of the walls which were erected in the middle ages, and on the landward side it is surrounded by a broad and deep ravine, the side towards the sea being protected by precipitous rocks. On the north-west of the town is a considerable plain or table-land, called *Piano di Sorrento*, about 1000 feet above the sea-level, surrounded and protected from the cold east winds by a range of hills; it is intersected by numerous gorges and ravines, studded with villas and farm-houses, and covered with orange groves and vineyards; all which combined render the vicinity of the city in a high degree picturesque.

It is celebrated for the mildness, dryness, and general salubrity of its climate, on which account it has been much resorted to both in ancient and modern times by invalids and convalescents. Among the Romans, the wine of S. was held in high reputation; it had to be kept about 25 years before it arrived at maturity. Nothing certain is known of the origin of S., but it is believed to be very ancient, and many ruins are pointed out by the *ciceroni* as being remains of Roman temples, &c. Tasso was a native of Sorrento.

SO'RTES BI'BLICÆ, SORTES VIRGILIA'NÆ. &c.—Among the ancients, a favorite kind of divination was that known as *Stichomancy*, or divination by lines of poetry. The method pursued was to select a number of verses from a poet, mix them together in an urn, draw one out at random, and from its contents to infer good or evil. As Virgil was the most popular and admired of all the Latin poets, his writings, and especially the *Æneid*, became the favorite book for this purpose, and it was undoubtedly this practice that laid the basis of the great reputation as a magician Virgil enjoyed during the middle ages. The Sibylline oracles were also much used for the same purpose. The practice did not cease with the introduction of Christianity; but instead of Virgil, or, to speak more correctly, alongside of Virgil, the Bible was employed to ascertain the future. In place however, of throwing lines into a 'heathen' urn, it was customary to open the book, as it were, accidentally, or to stick a pin between the leaves at hazard, and then open the book—the passage first catching the eye being regarded as pregnant with prophecy as to your future welfare.

Such lots drawn from Scripture were called, in the middle ages, *Sortes Biblicæ*, just as those drawn from Virgil were called *Sortes Virgilianæ*. The custom of using (or abusing) the Bible in this grossly superstitious way still lingers in England, Scotland, and other countries, but it is now more a frolic of children than aught else. The poet Hafiz is still so used in Persia.

SO'RTIE, an outrush of a beleaguered garrison, equivalent to SALLY (see SALLY-PORT).

SORUS. See FERNS.

SOSTENU'TO (Ital.), a term used in musical notation, to indicate a sustained mode of execution, continuous in respect of tone.

SOTTEVILLE-LÈS-ROUEN, a small town of France, in the dep. of Seine-Inférieure, 4 miles south of Rouen by railway. Pop. (1876) 11,278.

SOU, or SOL. See SOLIDUS.

SOUARI NUT. See CARYOCAR.

SOUDAN. See SUDAN.

SOUFFLÉ, a light and agreeable dish, consisting chiefly of the whites of eggs, to which other ingredients (chocolate, cheese, vanilla, orange-flower water, rose-water, various essences, &c.) are added, to give consistency, flavor, and variety. The materials have to be agitated with a whisk until the whole is in a creamy froth; which is then baked in a soufflé-pan, made of such a form as to fit into a dish or proper holder, that can be sent to table, and quickly handed round.

SOUKCHOU'M KALE', a seaport town of Asiatic Russia, in the government of Transcaucasia, on the east coast of the Black Sea. In 1831, a commercial port was established here, which, however, has surrendered its pre-eminence to Poti, a town about 70 miles to the S.E. S. K. was captured by the Turks at the beginning of the Russian war of 1877. Pop. (1867) 1612.

SOUL, in the language of spiritualistic philosophers, covers the whole region of mind, and is generally conceived of as a naturally imperishable entity, in relation with the body, but definable, for the most part, only in terms of the complete negation of material attributes. With this the popular conception in the main coincides, though it is less labored, and considerably less negative. In its original signification, the word appears to have stood for the principle of life both in men and in animals. The modes of conceiving it were various: it was sometimes regarded as the mere harmony of the bodily functions, and sometimes as a distinct entity of highly ethereal nature, and generally supposed to be seated in, or connected with the blood; but no essential distinction was made between the soul of man, and the soul of brutes. Very soon, however, the manifest superiority of man to the lower creation suggested difficulties, which were increased as the thought of an after-life, in a different sense from transmigration, was gradually developed. And in man, the constant war among his members, the opposition of passion and reason, as it began to be observed with the growing habit of introspection, called for some explanation which should apply to humanity only. To meet all such difficulties, a 'Trichotomy,' or three-fold division of the human constitution, was assumed, according to which a naturally immortal and rational element was supposed to make part of man, besides the animal soul (always variously conceived) which he shared with the brutes. Between the two distinct elements—the animal and the rational soul—the various mental energies were differently apportioned by different thinkers, according as those energies were thought more or less noble and divine.

Without going back upon obscure traditions regarding the beliefs of the early peoples, Plato's views may be cited as amounting to a Trichotomy, and in Aristotle there is the distinct mention of a noetic principle in man by the side of the animal soul. Later Greek schools put forward a similar view; and Philo, the forerunner of the Neo-Platonists, even spoke of *the soul of the soul*. Lucretius has the same curious expression, to which corresponds the distinction of Roman writers in general between *animus* and the animal soul, *anima*. The earliest Christian writings occasionally distinguish body, soul, and spirit (*pneuma*). Such a threefold division was unfamiliar to the Jewish mind, which appears to have rested in a kind of dualism, and was removed even from the common Greek philosophical expression, *pneuma* being the word employed by Stoic dualists to describe the fine ethereal nature of the material soul. It is hard to say whether a thorough-going Trichotomy was meant by the Christian writers, or whether the soul was not merged in either of the extreme elements—the coarse material body, or (as commonly conceived) the finely attenuated but still material spirit. Till about the 4th c., the language of Trichotomy prevailed in the Christian writings, but thenceforth the doctrine became suspect, having been specially appropriated by certain heretical sects, and soul and spirit came to be identified in substance, and distinguished only in function. Aquinas, and, later, Calvin, pronounced in favor of the dualistic rendering, after which modern popular expression has been moulded, chiefly through the predominant influence of spiritualism since the time of Descartes. This gives prominence to the word soul over spirit, except in religious and purely metaphysical aspects.

The successors of Descartes have followed him in calling the single soul at once both rational and sensitive; but in rejecting, almost without exception, his description of the lower animals as mere mechanical automata, they have ignored, without an attempt to explain, the real difficulty that he sought to get rid of, and that the Trichotomy sought to meet. The ancient doctrine has been

revived in various shapes by Paracelsus, Van Helmont, the anatomist Willis, De Maistre, and others.

The Egyptian doctrine of the soul is one of the most important, as it is the most ancient, for this nation appears to have been the first to declare that the soul was immortal. The genesis of the soul itself, however, is not defined by the monuments, although the existence of a cosmic soul, from which the others proceeded, is mentioned by ancient authors. The following may be gathered from a comparison of the papyri and monuments with the traditions handed down by the classical writers :—The soul itself, once separated from the cosmic or mundane soul, was supposed to undergo numerous transmigrations, passing from one animated body to another till its cycle of existence was fulfilled. The soul was considered to be essentially distinct from the body, and only connected with it through the link of life. It was represented in the hieroglyphs by several signs, as a basket of fire, a heron, a hawk with a human face, and a ram. Its nature was divine, but after death it passed to the great judgment in the hall of the Two Truths, where it was tried before Osiris and the forty-two assessors or demons of the dead, whose verdict determined its future destiny. This depended upon the sins it had perpetrated during life, and which more or less interfered with its transmigration through the necessary cycle of existence till its ultimate union with the deity, and reception into the Egyptian heaven. In the judgment, it was accused by the enemy or accuser; and after the judgment, it was either devoured or annihilated, passed to the reign of the Egyptian hell, or to the place of the metempsychosis, from which it entered some body of man or animal on the point entering into existence.

The great desire of the dying, indeed, was, that his soul should pass off the earth, its detention here preventing its ascent to the moon or heaven. The souls of the wicked passed into the Egyptian Hades, which the sun was supposed to traverse during the hours of the night. There they were subjected to punishments of a corporeal rather than spiritual nature—burned in brasiers, plunged into streams, kept in utter darkness, and deprived of the presence of the sun-god, uttering fearful howls and wails in the prisons within which they were confined. After the passing of the great judgment, the soul underwent a series of transformations and adventures in the future state. It was justified, as Osiris had been, against the accusations laid to its charge by evil spirits. It assumed the form of a hawk, heron, swallow, and of a snake with a human head—that of the cosmic soul. In the fields of the Aah-en-ru, or Ahlu, the Egyptian Elysium, it sowed and reaped the harvest of gigantic grain which grew in that happy plain. It ascended the *makhen*, or mystical bark, and rowed through the winding of the celestial Nile, passed the fiery caldron of the Hades, revisited the body, entered the boat of the Sun, and passed through different regions of the Egyptian hell, in which the damned were detained, arriving at last at the manifestation to light.

To preserve the body, in order that the soul might revisit and probably reanimate it at a future period, not only was it embalmed with the greatest care, but amulets were attached to it which were supposed to have the power of retaining the vital warmth, and of protecting it from destruction or decay. The period after which the soul was supposed to enter again into a human body was 3000 years, during which it transmigrated through other orders of animated nature. The principal dogmas, indeed, of the soul amongst these people were its creation or emanation from the cosmic soul, its transmigrations, and its final reception into heaven, where it lived in the boat of the Sun, and traversed the liquid ether in company with that luminary. The Pythagorean and Platonic schools seem to have drawn extensively from Egyptian sources in regard to the nature and destiny of the soul. The Brahmanical and Buddhistic notions of the soul have also much in common with the Egyptian. See BUDDHISM, TRANSMIGRATION.—Herodot. ii. 23; Plutarch, *De Isid.* c. 29; Hermes, *Clavis;* Prichard, *Egypt. Mythol.;* Rheinisch, *Denkm. in Miramar* (Wien, 1865); Tylor's *Primitive Culture* (1871).

SOULOUQUE. See FAUSTINUS I.

SOULS, CURE OF (Lat. *cura animarum*, care of souls), the technical phrase by which the canon law describes the charge which is given to a pastor, no matter of what degree of dignity, over the spiritual concerns of a flock; and the words especially imply the right of administering the sacraments. In this sense, the phrase is used to mark an important distinction between two classes of benefices or church livings—'benefices with,' and 'benefices without,' the cure of souls. Of the latter class are canonries, prebends, and the whole class known in the canon law as 'simple benefices.' Of the former are parochial cures, vicarial cures, and still more the higher charges of archbishop, bishop, &c.

SOULT, NICOLAS-JEAN DE DIEU, Duke of Dalmatia, and Marshal of France, the son of a notary, was born at Saint-Amens-la-Bastide, in the dep. of Tarn, March 29, 1769. In 1785, he enrolled himself as a private in the Royal Infantry regiment; and so distinguished himself by his steady obedience to discipline, indomitable *sang-froid*, and general intelligence, that in 1792 he became adjutant-major. His behavior at Fleurus gained for him (October 11, 1794) the brevet of general of brigade. From 1794 to 1799, he was employed on the eastern frontier, and in the retreat after the defeat of Stockach (March 25, 1799), his able handling of the rear-guard alone prevented the annihilation of the French army.

Appointed general of division (April 21, 1799), and put under Massena, whom he ably seconded in Switzerland and Italy, he was afterwards, on the warm recommendation of Massena, appointed by Napoleon to one of the four colonelships of the consular guards, and now became an ardent Napoleonist. This devotion, doubtless, was a great means of his obtaining the bâton of Marshal of France; but he most certainly justified his appointment by his brilliant achievements in the subsequent campaign against the Austrians, closed by the battle of Austerlitz, which he decided by piercing the Russian center. He also did good service in the Prussian campaign; and took an important, though not a prominent part, in the Russian campaign of 1806—1807, after which he was appointed governor of Berlin, and created Duke of Dalmatia. S. was next placed at the head of the second corps in Spain, pursued the retreating British, attacked them at Coruña, and though repulsed, forced them to leave all their matériel behind. He then conquered Portugal, and exercised vice-regal authority over it, but the sudden arrival of Wellesley at Coimbra, and of Beresford at Chaves, made him retreat rapidly to Galicia. In September 1809, he became commander-in-chief in Spain, gained a brilliant victory at Ocana (18th November); and at the commencement of the following year, overran and subdued Andalusia, continuing to command in person the southern army.

In attempting to succor Badajos, which he had captured and garrisoned (March 11), he was defeated by Beresford at Albuera (May 16, 1811). After the battle of Salamanca, and the advance of the British on Madrid, S. became thoroughly disgusted at the rejection of his admirable plans for transferring the theater of war to Andalusia, and demanded and obtained his recall; but on the news of Vitoria (q. v.) reaching Napoleon S., whom alone he considered capable of turning the tide of ill-fortune, was, in all haste, restored to the command-in-chief of the army of Spain. Now, however, it was not in Spain but in France that the contest had to be waged, and the advantage of numbers, discipline, and prestige were all on the enemy's side; nevertheless, by a system of military tactics which has been universally admired, he completely neutralized the consummate strategy of Wellington, and reduced the campaign, during the seven months it lasted, to a mere trial of strength, the defeats which he sustained at Orthez and Toulouse being due to the superiority of the British soldiers, not of their general. With his usual suppleness of character, he became an ardent royalist after the abdication of Napoleon; but on the return of the latter from Elba, he abandoned Louis XVIII., and became major-general of the imperial army.

After Waterloo, he rallied the army at Laon; and on July 3d, at the council of war, coincided with Carnot as to the uselessness of further resistance. To avoid the punishment due to his treachery, he published a memoir traducing Napoleon in the basest manner, and lauding the 'lawful princes' (i. e., the Bourbons); but in spite of this he was banished, and not recalled till May 1819; however, in the course of a few years more, he was restored to all his former honors, and took an active part in politics, and in the development of French industry. In 1838, he was sent as ambassador to England, and, as the great antagonist of Wellington, was received with the utmost enthusiasm. In 1845, he retired from active duty, was honored with the appointment of 'Marshal-general of France' and retired to his residence of Soultberg, where he died, November 26, 1851. In the following year, a statue of him, in white marble, was placed in the galleries of Versailles. See S.'s *Mémoires;* also, Napier's *History of the Peninsular War;* Theirs's *Histoire de la Révolution et de l'Empire;* and Salle's *Vie Politique du Maréchal S.* (1834).

SOUND (Lat. *sonitus*) is the impression produced on the Ear (q. v.) by the vibrations of the elastic medium, such as air or water, in which it is plunged. That this is the case, is proved, *first*, by the fact, that a bell or tuning-fork *in vacuo* gives no sound when struck; *second*, by the fact, that mere currents, as such (winds, running water, &c.), do not produce the sensation of sound until they are frittered down into vibratory motions by obstacles.

The most untutored ear distinguishes at once between a mere *noise* and a *musical note*. It of course distinguishes a *loud* sound from a faint one. Moreover, it distinguishes musical notes from one another by their shrillness or gravity, or, as it is technically called, their *Pitch*. Again, as in the case of vowel-sounds sung to the *same* musical note, or as in the case of different instruments (flute and violin, for instance) playing the same note, it distinguishes something further—which is called the *Quality* of the

note. It is on the pitch of notes that the Theory of Music (q. v.) is based, for the quality is only of importance in giving variety, as in orchestral music—or in giving richness of tone in a solo. The most perfect *music*, so far as theory goes, may be executed on the poorest instrument, but it gives little pleasure from the want of richness or quality. In the same way, a singer may possess faultless intonation, yet the performance, though *musically* perfect, may, from the harsh quality of the voice, be unpleasant. We intend, in the present article, to avoid everything connected with music, and have made these remarks to show that there is something in the theory of sound more profound than is contemplated in the theory of music.

The questions we have now to discuss are:

1. What constitutes the difference between a mere noise and a musical note?
2. On what does the pitch of a note depend?
3. On what does its quality depend?

The answers to these queries are all contained in the following statement:

Every musical note consists in the repetition, at equal small intervals of time, of some definite noise; the pitch depends on the rate of repetition; and the quality upon the nature of the fundamental noise.

Rough experimental illustrations of the parts of this statement are easily given, more refined ones will be afterwards alluded to. If, for instance, the edge of a card be held to a revolving toothed-wheel, a definite noise is produced as each tooth bends the card and allows it to spring back. While the wheel revolves slowly, we can distinguish these successive noises; but when it is revolving so fast that they are no longer separately distinguishable, the character of the sound changes completely. It now becomes continuous, and so far as the ear can detect, uniform, and thus becomes a musical note (with such an apparatus, not a pleasing one). As the wheel is made to revolve faster and faster, the pitch of the note rises, till it becomes a sort of shriek, and finally becomes inaudible. The *Sirène* (q. v.) gives another excellent illustration. In this case, the fundamental noise is produced by a puff of air escaping from an orifice; and we observe, just as before, that the greater the number of such puffs per second, after they have become so frequent as to be separately undistinguishable, the higher is the pitch of the musical note produced.

Now, if by machinery we arrange matters so that the sirène and the toothed-wheel give the number of puffs and the number of impacts on the card the same per second, the musical note produced by each has the same pitch. But the notes differ greatly in quality, the one being exceedingly soft and pleasant, the other harsh and grating. The pitch, therefore, depends on the number of noises per second, and the quality upon the nature of the fundamental noise. We shall find a complete theoretical proof of this later.

The general nature of the mechanical process by which sound is propagated in the air will be illustrated, and compared with other cases of wave-motion, in our article on WAVES. Meanwhile, it is only necessary for us to observe that, as the velocity of sound is ten times greater than that of wind in the most violent hurricane, it is not *air* itself which is transferred from place to place, but a *state of disturbance* (condensation or rarefaction) of the air. Each successive layer of air in the path of the sound suffers this disturbance in turn, and by virtue of its Elasticity (q. v.), passes it on to the next.

Newton was the first who attempted to deduce from mechanical principles the velocity of sound, but only for the particular case in which each particle of air, in the path of the sound, is supposed to move backwards and forwards according to the same law as the bob of a Pendulum (q. v). He showed that this species of motion is consistent with the elastic properties of air, as given by Boyle's or Mariotte's Law (q. v.), viz., that the pressure of air is proportional to its density. The velocity of sound in this case is of course to be found from the time which elapses between the commencement of the motion of any one particle of air, and that of another at a given distance from it, in the direction in which the sound is moving. The numerical result deduced by Newton with the then received experimental data for the compressibility of air, was 979 feet per second. This investigation was very defective, applying, in fact, solely to the special case of a pure musical note, continually propagated without lateral divergence; yet the solution obtained by Lagrange from a complete analysis of the question, gave precisely the same mathematical result.

But, by direct measurements, carefully made, by observing at night the interval which elapses between the flash and the report of a cannon at a known distance, the velocity of sound has been found to be considerably greater—in fact, about 1090 feet per second, at the temperature of freezing water.

Newton seeks for the cause of this discrepancy between theory and observation in the idea that the size of the particles of air is finite compared with their mutual distance; and that sound is instantaneously propagated through the particles themselves. Thus, supposing the particles to have a diameter $\frac{1}{9}$th of the distance between them, we must add $\frac{1}{9}$th to the space traveled by sound in a second, i. e., to the velocity—which will thus be brought up to $(1 + \frac{1}{9})$ 979 feet = 1088 feet nearly, which is a very close approximation to the actual value given above.

This is not one of Newton's happiest conjectures—for, independent of the fact that such an assumption would limit definitely the amount of compression which air could undergo, and, besides, is quite inconsistent with the truth of Boyle's law for even moderate pressures, it would result from it that sound should travel slower in rarefied, and quicker in condensed air. Now, experiment shows that the velocity of sound is unaffected by the height of the barometer; and, indeed, it is easy to see that this ought to be the case. For in condensed air the pressures are increased proportionally to the increase of condensation, and the mass of a given bulk of air is increased in the same proportion. Hence, in a sound-wave in condensed air, the forces and the masses are increased proportionally, and thus the rate of motion is unaltered. But the temperature of the air *has* an effect on sound, since we know that the elastic force is increased by heat, even when the density is not diminished; and therefore the velocity of sound increases with the temperature at the rate of about $4\frac{1}{2}$ feet per Fahrenheit degree, as is found by experiment.

Newton's explanation of the discrepancy between theory and experiment being thus set aside, various suggestions were made to account for it; some, among whom was Euler, imagining that the mathematical methods employed, being only approximate, involved a serious error.

The explanation was finally given by Laplace, and is simple and satisfactory. When air is *suddenly* compressed (as it is by the passage of a sound-wave), it is heated; when suddenly rarefied, it is cooled, and this effect is large enough to introduce a serious modification into the mathematical investigations. The effect is in either case to *increase* the forces at work—for, when compressed, and consequently heated, the pressure is greater than that due to the mere compression—and, when rarefied, and consequently cooled, the pressure is diminished by more than the amount due to the mere rarefaction. When this source of error is removed, the mathematical investigation gives a result as nearly agreeing with that of observation as is consistent with the unavoidable errors of all experimental data. It is to be observed that, in noticing this investigation, nothing has been said as to the pitch or quality of the sound, for these have nothing to do with the velocity.

It must, however, be remarked here that, in the mathematical investigation, the compressions and rarefactions are assumed to be very small; i. e., the sound is supposed to be of moderate intensity. It does not follow, therefore, that very violent sounds have the same velocity as moderate ones, and many curious observations made during thunder-storms seem to show that such violent sounds are propagated with a greatly increased velocity. (See a paper by Earnshaw in the *Phil. Mag.* for 1861.) It is recorded that in one of Parry's arctic voyages, during gun-practice, the officer's command 'Fire' was heard at great distances across the ice *after* the report of the gun.

Since sound consists in a wave-propagation, we should expect to find it exhibit all the ordinary phenomena of Waves (q. v.). Thus, for instance, it is *reflected* (see ECHO) according to the same law as light. It is *refracted* in passing from one medium to another of different density or elasticity. This has been proved by concentrating in a focus the feeble sound of the ticking of a watch, and rendering it audible at a considerable distance, by means of a lens of collodion films filled with carbonic acid gas.

Sounds *interfere* to reinforce each other, or to produce silence; just as the crest of one wave in water may be superposed on the crest of another, or may apparently destroy all motion by filling up its trough. The simplest mode of showing this is to hold near the ear a vibrating tuning-fork and turn it slowly round its axis. In some positions, the sounds from the two branches reinforce, in others they weaken, each other. But if, while the sound is almost inaudible, an obstacle be interposed between the ear and one of the branches, the sound is heard distinctly. Beats, which will shortly be alluded to, form another excellent instance.

To give an idea of the diminution of loudness or intensity of a sound at a distance from its source, let us consider a series of spherical waves diverging from a point. The *length* of a wave, as we know from the theory, does not alter as it proceeds. (Indeed, as we shall presently see, the pitch of a note depends on the length of the wave; and we know that the pitch is not altered by distance.) Hence, if we consider any one spherical wave, it will increase in radius with the velocity of sound, but its thickness will remain unaltered.

The same disturbance is thus constantly transferred to masses of air greater and greater in proportion to the *surface* of the spherical wave, and therefore the amount in a given bulk (say a cubic inch) of air will be inversely proportional to this surface. But the surfaces of Spheres (q. v.) are as the squares of their radii

—hence the disturbance in a given mass of air, i. e., the loudness of the sound, is inversely as the square of the distance from the source. This follows at once from the law of conservation of energy (see FORCE), if we neglect the portion which is constantly being frittered down into heat by fluid friction. All sounds, even in the open air, much more rapidly in rooms, are extinguished ultimately by conversion into an equivalent of heat. Hence sounds really diminish in intensity at a greater rate than that of the inverse square of the distance; though there are cases on record in which sounds have been heard at distances of nearly 200 miles. But if, as in speaking-tubes and speaking-trumpets, sound be prevented from diverging in spherical waves, the intensity is diminished only by fluid friction, and thus the sound is audible at a much greater distance, but of course it is confined mainly to a particular direction.

As already remarked, the purest sounds are those given by a tuning-fork, which (by the laws of the vibration of elastic solids) vibrates according to the same law as a pendulum, and communicates exactly the same mode of vibration to the air. If two precisely similar tuning-forks be vibrating with equal energy beside each other, we may have either a sound of double the intensity, or anything less, to perfect silence, according to their relative *phases*. If the branches of both be at their greatest elongations simultaneously, we have a doubled intensity—if one be at its widest, and the other at its narrowest, simultaneously, we have silence, for the condensation produced by one is exactly annihilated by the rarefraction produced by the other, and *vice versâ*. But if the branches of one be loaded with a little wax, so as to make its oscillations slightly slower, it will gradually fall behind the other in its motion, and we shall have in succession every grade of intensity from the double of either sound to silence. The effect will be a periodic swelling and dying away of the sound, and this period will be longer the more nearly the two forks vibrate in the same time. This phenomenon is called a *beat*, and we see at once from what precedes, that it affords an admirable criterion of a perfect *unison*, that is, of two notes whose pitch is the same. It is easy to see, by the same kind of reasoning, that if two forks have their times of vibration nearly as 1 : 2, 2 : 3, &c.—i. e., any simple numerical ratio—there will be greater intervals between the beats according as the exact ratio is more nearly arrived at.

We must now consider, so far as can be done by elementary reasoning, the various simple modes of vibration of a stretched string, such as the cord of a violin. Holding one end of a rope in the hand, the other being fixed to a wall, it is easy (after a little practice) to throw it into any of the following forms, the whole

Fig. 1.

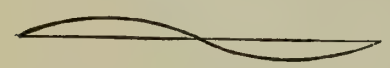


Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

preserving its shape, but rotating round the horizontal line. If the tension of the rope be the same in all these cases, it is easy to see that the times of rotation must be inversely as the number of equal segments into which the rope is divided; for the various parts will obviously have the same form; and the masses and distances from the axis of rotation being proportional to their lengths, the Centrifugal Forces (q. v.) will be as the squares of the lengths, and inversely as the squares of the times of rotation. But these centrifugal forces are balanced by the components of the tensions at the extremities, in directions perpendicular to the horizontal line; which are, by hypothesis, the same for all the figures. Hence the time of rotation is directly as the length of each segment.

Now (see PENDULUM) any such rotation is equivalent to two mutually perpendicular and independent pendulum vibrations of the cord from side to side of the horizontal line. Thus, a violin-string may vibrate, according to the pendulum law, in one plane, either as a *whole* (fig. 1), as *two halves* (fig. 2), as *three thirds* (fig. 3), &c.; and the times of vibration are respectively as 1, $\frac{1}{2}$, $\frac{1}{3}$. . . . . Nay, more, any two or more of these may coexist in the same string, and thus, by different modes of bowing, we may obtain very different combinations of simple sounds: a *simple sound* being defined as that produced by a single pendulum motion, such as that of a tuning-fork, or one of the uncomplicated modes of vibration of a string.

The various simple sounds which can be obtained from a string are called *Harmonics* of the fundamental note; the latter being the sound given by the string when vibrating as a whole (fig. 1). For each vibration of the fundamental note, the harmonics have two, three, four, &c. Of these, the first is the octave of the fundamental note; the second the twelfth, or the fifth of the octave; the third the double octave; and so on. Thus, if we have a string whose fundamental note is C, the series of simple sounds it is capable of yielding is :

$$C, C_1, G_1, C_2, E_2, G_2 (B\flat_2), C_3, D_3, E_3, \&c.$$

Of those written, all belong to the ordinary musical scale except the seventh, which is too flat to be used in music. This slight remark shows us at once how purely artificial is the theory of music, founded as it is, not upon a physical, but on a sensuous basis.

To produce any one of these harmonics with ease from a violin-string, we have only to touch it lightly at $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. of its length from either end and bow as usual. This process is often employed by musicians, and gives a very curious and pleasing effect with the violoncello or the double-bass. The effect of the finger is to reduce to rest the point of the string touched; and thus to make it a point of no vibration, or, as it is technically called, a *Node*.

In the case of a pianoforte wire, a blow is given near one end, producing a displacement which runs back and forward along the wire in the time in which the wire would vibrate as a whole. The successive impacts of this wave on the ends of the wire (which are screwed to the sounding-board), are the principal cause of the sound. But more of this case later.

The theory of other musical instruments is quite as simple. Thus, in a flute, or unstopped organ-pipe, the sound is produced by a current of air passing across an orifice at the closed end. This produces a wave which runs along the tube, is reflected at the open end, runs back, and partially intercepts the stream of air for an instant, and so on. Thus the stream of air is intercepted at regular intervals of time, and we have the same result as in the Sirène (q. v.). In this case, there is *one* node only, viz., at the middle of the pipe. If we blow more sharply, we create two nodes, each distant from an end by $\frac{1}{4}$ of the length of the tube. The interruptions are now twice as frequent, and we have the first harmonic of the fundamental note. And so on, the series of harmonics being the same as for a string.

We may easily pass from this to the case of an organ-pipe closed at the upper end. For if, while the open pipe is sounding its fundamental note, a diaphragm be place at the node, it will not interfere with the motion, *since the air is at rest at a node*. That is, the fundamental note of a closed pipe is the same as that of an open pipe of double the length. By examining the other cases in the same way, we find that the numbers of vibrations in the various notes of a closed pipe are in the proportions 1 : 3 : 5 : 7 : &c., the even harmonics being wholly absent.

There is another kind of organ-pipe, called a reed pipe, in which a stream of air sets a little spring in vibration so as to open and close, alternately, an opening in the pipe. If the spring naturally vibrates in the time corresponding to any harmonic of the pipe, that note comes out with singular distinctness from the combination—just as the sound of a tuning-fork is strongly reinforced by holding it over the mouth-hole of a flute which is fingered for the note of the fork. If the spring and the tube have no vibration in common, the noise produced is intolerably discordant. The Oboe, Bassoon, and Clarionet are mere modifications of the reed-pipe; and so are Horns in general, but in them the reed is supplied by the lip of the performer. Thus, a Cornet, a Trumpet, or a French Horn, gives precisely the same series of harmonics as an open pipe.

The statements just made as to the position of the nodes in a vibrating column of air are not strictly accurate, for the note is always found to be somewhat *lower* than that which is calculated from the length of the tube and the velocity of sound. Hopkins showed experimentally that the distance between two nodes is always *greater* than twice the distance from the open end to the nearest node. The mathematical difficulties involved in a complete investigation of the problem were first overcome by Helmholtz in 1859, in an admirable paper published in *Crelle's Journal*. The results are found to be in satisfactory accordance with those previously derived from experiment.

We have now to consider the subject of the quality of musical sounds; and one of its most important branches, what constitutes the distinction between the various vowel-sounds. It had long been recognized that the only possible cause of this distinction between sounds *musically identical* must lie in the nature of the fundamental noise, or, to express it differently, the nature of the periodic motion of each particle of air. But it appears that Helmholtz was the first to enter upon a complete examination of the point, both mathematically and experimentally, and the results

he has arrived at form by no means the least remarkable of the contents of his excellent work, *Die Lehre von den Tonempfindungen*, recently published.

It was established by Fourier, that any periodic expression whatever may be resolved into the sum of a number of simple harmonic terms, whose periods are, respectively, that of the original expression, its half, its third part, &c. Hence any periodic motion of air (i. e., any musical sound) may be resolved into a series of simple pendulum vibrations (i. e., pure musical sounds, such as those of tuning-forks), the first vibrating once in the given period, the second twice, and so on. These notes are, as we have seen, the several harmonics of the lowest. Hence the quality of a musical sound depends upon the number and loudness of the harmonics by which it is accompanied.

Two experimental methods were employed by Helmholtz, one analytical, the other synthetical. In the first he made use of resonance-cavities fitted to the ear, and giving scarcely any indication of external sounds until one is produced which exactly corresponds in pitch with the note which the cavity itself would yield. With a series of such cavities, tuned to the several harmonics of some definite note, the note was examined when played on various instruments, and when sung to different vowel-sounds. It was thus ascertained which harmonics were in each case present, and to what extent, producing the particular quality of the sound analyzed. The second method was founded on the fact, already noticed, that a tuning-fork gives an almost pure musical sound (i. e., free from harmonics). A series of tuning-forks, giving a note and its harmonics, were so arranged as to be kept constantly in vibration by an electro-magnetic apparatus.

Opposite to each was fixed a resonance-cavity, exactly tuned to it, and capable of being opened more or less at pleasure. When all the cavities were shut, the sound was scarcely audible; so that by opening them in various ways, any combination of harmonics might be made to accompany the fundamental note. These combinations were varied by trial, until the quality of the resultant sound was brought to represent as nearly as possible that of some vowel. The results of this second series of experiments coincided with those of the first. It appears from these investigations that the German U is the quality of a simple sound, though it is improved by adding faintly the two lowest harmonics; that O depends mainly on the presence of the third harmonic; and so on with the other sounds. It also appears, and it is well known by experience, that different vowel-sounds, to be sung with accuracy, require to be sung to different notes, the proper note being that for which the cavity of the mouth is adapted for the production of the accompanying harmonics which determine the quality of the particular vowel.

In strings and pipes, as we have seen, the higher notes are strictly harmonics of the fundamental note, and therefore the sounds of instruments which depend on these simple elements are peculiarly adapted for music. On the other hand, when as in masses of metal, &c., the higher notes are not harmonics of the fundamental note, the mixed sound is always more or less jarring and discordant. Such is the case with bells, trumpets, cymbals, triangles, &c.; and, in fact, these sounds are commonly characterized as 'metallic.' To produce from such instruments a sound as pleasing as possible, they must be so struck that as few as possible of the higher notes are produced, and these as feebly as possible. Thus, for instance, to get the most pleasing sound from a pianoforte-wire, it should not be struck at the middle, as in such a case the first, third, fifth, &c. harmonics of the fundamental note will be wanting. If, however, it be struck at about ⅛th of its length from one end, the harmonics produced will be mainly the first five; and these all belong to the chord of the fundamental note. A valuable recent work is Lord Rayleigh's *Theory of Sound* (2 vols. 1878).

SOUND (A.S. and Ger. *Sund;* according to Grimm, for *Suumd*, from the root of *Swim*), a word signifying generally a strait or narrow sea-way, but applied specially to the strait which leads from the Cattegat into the Baltic Sea, between Sweden on the east, and the Danish island of Seeland on the west. It forms the usual passage from the north to the Baltic Sea, is 40 miles long, and nearly 3 miles broad at its narrowest part, between the towns of Helsingborg and Elsinore. Its entrance is defended by the strong castle and fortress of Kronborg. See ELSINORE.

SOUND DUTIES, certain dues formerly payable to the Danish government by all vessels passing the Sound or strait separating Sweden from Seeland. These duties originated in an agreement between the king of Denmark and the Hanse Towns in 1348, by which the former undertook to maintain the light-houses in the Cattegat, and the latter to pay duty for them. England became bound to pay duty by a treaty of date 1450, and other countries followed. The Sound Duties were abolished on 14th March 1857, by a treaty between Denmark and other powers. A pecuniary compensation of £3,386,528 (the share contributed by Great Britain being £1,125,206) was stipulated to be paid to Denmark, which was to be held bound to maintain the light-houses and superintend the pilotage of the Sound.

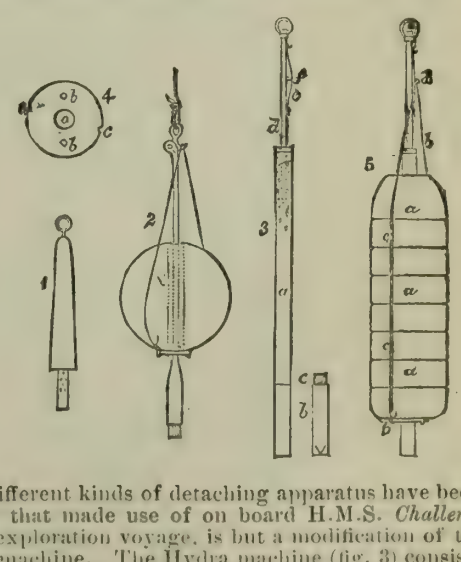
SOUNDING is the act of ascertaining the depth of the water. This is done either for purposes of navigation in piloting a ship among shoals or rocks, for ascertaining her position where the depth and nature of the bottom is previously known, or constructing a chart, &c. It is generally effected by means of a marked line, to which is attached a tapered lead, the bottom or foot of the lead being hollowed to receive some grease or tallow to which a portion of the soil at the bottom of the sea will adhere. Other methods have been devised for ascertaining depth, such as by a rotating fan-wheel, &c.; but the first method is that still most generally used for ordinary depths.

Sounding Lead.

SOUNDING, DEEP-SEA. Until within a few years, past, the term *deep sounding* was understood to be that in which a ship sounded to ascertain her position, and where the depth exceeded that which could be obtained with the lead thrown by the hand, or hand-lead; but the necessities of telegraphic communication across the ocean, by means of cables containing insulated wires, have caused the ocean to be measured at depths which were never before considered necessary, or even practicable.

The act of obtaining a deep-sea sounding may be said to consist of two parts—1. To get the sinkers to the bottom as quickly as possible with the line straight up and down; and 2. To bring a portion of the soil of the bottom, as a proof, to the surface; this necessitates the use of a small but strong line, with heavy sinkers and a detaching apparatus for freeing the sinkers when they reach the bottom, as from the smallness of the line and the great friction of all passing through the water, the strain of bringing the sinkers up would be too great for its strength. It may be stated that there is no difficulty whatever in obtaining a sounding, and regaining the sinker, with bottom specimen, up to a depth of 1000 to 1200 fathoms (1½ miles), by means of a heavy lead fitted with a valved tube (fig, 1); but when the depth exceeds 2000 fathoms, the difficulties in obtaining a correct sounding increase in a compound ratio with the depth.

The first detaching apparatus (fig. 2) was devised by Mr. Brooke, a midshipman of the United States navy: it is extremely simple and efficient. It consists of a rod with a movable hook at the upper end, and a tube at the lower end. The sinker is a perforated shot, through which the tube passes, and by means of a ring below the shot the weight is suspended to the hook by wire, the hook being kept up by the sounding line; the tube is filled with cut quills. When the weight touches the ground, the line is slackened, the hook falls, and the suspending wire being freed, the shot slides off, while the quills, being thrust into the soil, secure a small portion, which is brought up with the rod.



Many different kinds of detaching apparatus have been invented since, but that made use of on board H.M.S. *Challenger*, in her deep-sea exploration voyage, is but a modification of the original Brooke's machine. The Hydra machine (fig. 3) consists of a tube of iron, 2½ inches in diameter and 4½ feet in length, *a*; the lower 12 inches, *b*, is separate from, but screws to the upper part at *c*; it is fitted with a butterfly valve at the lower end, to retain the bottom specimen. At the upper end of the tube is a piston-rod *d*, which moves freely in the tube. To the upper part of this rod is fixed a steel spring, bent in a bow *e*; a slit in the spring is adapted to the hook *f*, which protrudes beyond the spring when the latter is forced back. The sinkers (fig. 4) are cast-iron discs of half a cwt., each, the hole through the center, *a*, being sufficiently large for the sounding-tube to pass through. They are made to fit each

other by means of small conical protuberances on the one side, and corresponding hollows on the other, *b*; so that when placed one on another, the groove *c* in the one weight corresponds to that on the other. The upper and lower sinkers differ a little in form.

When a sounding is to be taken, the machine is prepared as in fig. 5, a wooden stand being used for the purpose. The sinkers, *a*, *a*, are piled to the required weight, say 4 cwt.; the tube is then passed through them, and an iron ring (with a bight of iron wire attached), *bb*, is passed on the lower end of the tube, and the wire led along the continuous grooves on each side of the sinkers *c*, and the bight passed over the hook *d*, the spring being pressed back. When the weight of the sinkers rests on the ring, and is supported by the wire, the weight keeps the spring pressed in; but as soon as the sinkers touch the ground, and the weight is relieved from the wire, the spring throws it off the hook, and the tube is drawn clear through the sinkers.

When the tube, with sinkers complete, is ready, it is carefully hoisted over the side, lowered gently into the sea, and eased down one or two hundred fathoms before being let go. It is then let go, and the passing of each 100-fathoms mark is timed and recorded in a printed form made to contain all the particulars of the sounding.

Sir William Thomson, F.R.S., has invented a mode of deep-sea sounding by using piano wire instead of hempen lines, which promises to obviate much of the present difficulty in deep-sea sounding.

Many very deep soundings are on record, but the two deepest well-authenticated soundings are among those obtained by H.M.S. *Challenger*. The first was about 80 miles to the northward of the Virgin Islands, the depth being 3875 fathoms, or nearly 4½ miles. Unfortunately, not thinking that so near the islands so great a depth would be found, only three cwts. of sinkers were used (the usual quantity for such extreme depths being 4 cwts.); this weight, with a one-inch line, took an hour and twelve minutes to reach the bottom. As the ascertainment of the sinkers reaching the bottom depends on the time intervals, it may be stated that the line let free to run with this weight would take about 43 seconds running out the first 100 fathoms, and the time increases as nearly as possible three seconds for each successive 100 fathoms; so that when the interval is prolonged beyond this rate, the sinker has reached the bottom. On this occasion the last 50 fathoms ran out at the rate of 2 minutes 36 seconds per 100 fathoms. The other was to the north of New Guinea, where the depth was 4475 fathoms, or more than five miles.

An idea of the average depth of the North Atlantic Ocean may be had from the fact that of 108 soundings obtained by the *Challenger*, 48 were between 1000 and 2000 fathoms, 56 between 2000 and 3000, whilst only the other 4 exceeded 3000.

SOUP (A.-S. *sup-an*, to sip or sup) is a well-known form of food, obtained either from flesh and vegetables, or from vegetables alone. Before noticing the most important varieties of soup, it is expedient that we should have a clear idea of what soup really is, or, in other words, what relation soup bears to the solid ingredients which enter into its composition. The researches of Liebig have thrown much light upon this point. When finely-chopped muscular flesh (or butcher-meat) is lixiviated with cold water, and exposed to pressure, there is left a white fibrous residue consisting of muscular fibres, of connective or areolar tissue, and of vessels and nerves. This lixivated flesh is of precisely the same quality from whatever animal it is obtained, communicates no flavor to water in which it is boiled, cannot be masticated, and as Liebig observes, 'even dogs reject it.' When the cold water has taken up all that it is capable of extracting, it is found that it has dissolved from 16 to 24 per cent. of the dry chopped flesh.

This watery infusion contains all the savory and much of the nutriment matter of the flesh, and is usually of a reddish tint, from the presence of a little of the coloring matter of the blood. On gradually heating it to the boiling-point, it is observed that the albumen of the flesh (varying in amount from 2 to 14 per cent., according as the animal was old or young) separates in nearly colorless flakes when the temperature has risen to 133°, while the coloring-matter of the blood does not coagulate till the temperature rises to 158°. The liquid is now clear, and of a pale yellowish tint; and as it reddens litmus-paper, it must contain a free acid. The infusion of flesh thus prepared has the aromatic taste and all the properties of a soup made by boiling the flesh. When evaporated, it becomes darker-colored, and finally brown; and on ceasing to lose weight, there is obtained a brown, somewhat soft mass of 'Extract of Flesh,' or 'Portable Soup,' amounting to about 12 per cent. of the weight of the original flesh, supposed to be dried. 'This extract,' says Liebig, 'is easily soluble in cold water, and when dissolved in about 32 parts of hot water, with the addition of some salt, gives to this water the taste and all the peculiar properties of an excellent soup. The intensity of the flavor of the dry extract of flesh is very great; none of the means employed in the kitchen is comparable to it in point of flavoring power.'

The soup thus made of the flesh of different animals (as, for example, the ox and the fowl) possesses, along with the general flavor common to all soups, a peculiar taste, which distinctly recalls the smell or taste of the roasted flesh of the animal employed. In order to obtain the strongest and best-flavored soup, chopped flesh should be slowly heated to boiling with an equal weight of water; the boiling should only be continued for a few minutes (for prolonged boiling only gives rise to the formation of gelatine, a substance of no nutrient value, from the connective tissue of the flesh), and the soup should be then strained off from the solid residue. As a matter of economy, it is often desirable that the meat should be left in an eatable state, which is not the case with soup made according to the preceding directions. To attain this end, the joint or mass of flesh should be set on the fire with cold water, which should be gently heated to boiling; the flesh thus undergoes a loss of soluble and savory matter, while the soup becomes richer in them. The thinner the piece of flesh is, the greater is the loss which it experiences. Hence the method of boiling which yields the best soup, gives the driest, toughest, and most tasteless meat. 'The juice of flesh,' says Liebig, 'contains the food of the muscles; the muscular system is the source of all the manifestations of force in the animal body; and in this sense we may regard the juice of flesh as the proximate condition of the production of force. Soup is the medicine of the convalescent, and as a means of restoring the exhausted strength, it cannot be replaced by any article of the Pharmacopœia. Its vivifying and restoring action on the appetite, on the digestive organs, the color and the general appearances of the sick, is most striking.'

Most soups contain an admixture of meat and vegetables in their preparation; but many good soups can be made either entirely without the use of flesh, or with fish in place of flesh. In the former class may be placed pea-soup (which is, however, much improved if a piece of bacon enters into its composition), green-pea soup, carrot-soup, potatoe-soup, asparagus-soup; while for fish-soup, pike, tench, and eels are specially used. Recipes for such soups will be found in many of the best cookery-books, and for the vegetable soups especially in the vegetarian cookery-books. The basis of all good soups, excepting those in the preceding category, is *stock*, or broth made from all sorts of meat, bones, remains of poultry or game, &c., put together, and stewed in the *stock-pot*.

Public attention was some time ago called to Liebig's *Soup for Children*. This preparation, which is hardly entitled to be called a soup, as the word is generally understood in this country, is made as follows: Take 1 oz. (one large table-spoonful) of seconds flour, and mix it very slowly and carefully with 10 oz. of cold skimmed milk, until the whole is smooth; add 7½ grains of bicarbonate of potash, dissolved in a tea-spoonful of water (if 60 grains of the potash be dissolved in 1 oz. of water, 1 tea-spoonful must be used at a time), and then heat it gently to the boiling point, and keep it boiling for five minutes. Stir it well while it is being heated; add to the whole fluid 1 oz. (1 large dessert-spoonful) of malt flour (malt ground in a coffee-mill and sieved), mixed with 2 oz. of water, and stir it well. Cover the pan, and let it stand for half an hour in water which is nearly boiling, so as to keep the fluid warm; then strain through a fine sieve, and bottle it. This quantity is sufficient for a day's supply for a child under two ysars of age, and a quart of milk should be added to it.

SOUTANE (Ital. *sottana*, Fr. *soutane*, Lat. *talaris*, i. e., *vestis*, 'a garment reaching to the ankles'), the name usually given in France and Italy to the outer garment worn in civil life (commonly with a flowing over-dress or robe) by Roman Catholic ecclesiastics, when the strict law of clerical costume is in force; and also ordered to be worn under the priestly robes used in the public ministerial offices of the clergyman. In England, it was called cassock. It is not peculiar to bishops, priests, or even to clerics in holy orders, but may be worn by all who have received even the TONSURE (q. v.). Indeed, the Council of Trent (*Dic. de Reform.*, sess. 23, c. vi.) declares that no cleric shall be held entitled to the 'privilege of clerics,' unless he shall wear the soutane. The ordinary material of the soutane is serge or woollen cloth; but it is often of more precious stuffs. The color for the secular clergy is commonly black; but dignitaries wear other colors. Thus, the pope wears a white—cardinals, a red—bishops, a violet—many canons, a blue soutane; and in religious orders and collegiate bodies, the color is regulated by special laws, which need not be particularized. Its use, as obligatory, was very general in former times, but it has gradually fallen off since the French Revolution. It is but little worn in Germany, even in the southern provinces; and in Italy, except in the former Papal States, it is much less universal than it was 30 years since. In all places, however, it is strictly required to be worn under the sacred vestments by a priest administering the sacraments, or otherwise officiating publicly.

SOUTH, ROBERT, D.D., the son of a London merchant, was born at Hackney in 1633. His earlier education he received at

Westminster School, of which Dr. Busby was then master; and in 1651, he became a student at Christchurch, Oxford. In 1655 and 1657 successively, he took his degrees of Bachelor and Master of Arts; he was ordained in 1658; and in 1660, he was appointed University Orator. In this function he was fortunate enough to please the Lord Chancellor Clarendon on his installation as Chancellor of Oxford, and in reward of his complimentary periods, S. was made his domestic chaplain. In 1663, he took his degree as Doctor of Divinity; the same year saw him promoted to a prebendary stall at Westminster; and in 1670, he became a canon of Christchurch, Oxford. In 1677, Laurence Hyde, son of the Chancellor, being sent to Poland as ambassador, he was accompanied thither by S., who had been his tutor, and was the object of his warm regard. Shortly after his return, the rectory of Islip, in Oxfordshire, was conferred upon him, and he was made chaplain-in-ordinary to Charles II. He might readily now have become a bishop, but through this and the succeeding reign, he steadily continued to decline the offers of higher preferment pressed upon him.

The designs of James II., tending to a Roman Catholic revival, he regarded with deep disapproval and alarm; but so strong was his sense of the duty of submission to the reigning monarch, that he declined all share in the conspiracy to oust him in favor of the Prince and Princess of Orange. When, however, the Revolution was accomplished, he gave in his adhesion to it. But, to his honor, he refused to profit in the way of preferment, by the deprivation of such of the higher dignitaries of the church as could not conscientiously go along with him in recognition of the new order of things. A stanch and even bigoted adherent of the Church of England, he continued to wage unsparing war from the pulpit, and with his pen, against Puritanism and every other form of dissent, occasionally occupying himself with discussions more strictly theological, till in July 1716, death came to conclude his controversies. He is now chiefly remembered by his sermons; they are masterpieces of vigorous sense and sound English, and abound in lively and witty turns, not always in severely decorous consonance with the seriousness of the subject matter. As a man, S. seems to have been of sound and estimable character; of pure life, and unblemished integrity. His entire works were sent from the Clarendon press in 7 vols. (1823), 5 vols. (1843). An edition in 2 vols. appeared at London in 1850.

SOUTHA'MPTON, a municipal and parliamentary borough, important seaport, and county of itself, in the south of Hampshire, 78 miles south-west of London by the London and South-western Railway. It occupies a peninsula at the head of Southampton Water, and between the estuary of the Test or Anton on the west and south, and the mouth of the Itchen on the east. The High Street, which is the principal thoroughfare, extends from the waterside to the Bargate, and thence to the outskirts of the town. Crossing the High Street at right angles, are many important streets, and handsome lines of new houses are found in the northern and western suburbs. S. is furnished with the usual municipal and other institutions common to all thriving towns. St. Michael's Church, the oldest in the borough, contains Norman tower arches, and several of the private houses are of Norman architecture. The *Domus Dei*, or God's House, dates from the end of the 12th c., and is one of the earliest hospitals in England. The docks can float the largest steamers, and have been greatly extended and improved; the revenue of the Dock Company in 1875 was £103,426. S. is the place of departure and arrival of the West India and Brazil, the Mediterranean, East Indian, China, and Australian, and the South African mail steam-packets.

There is considerable traffic between S. and the Channel Islands and French coast, and also a large cattle-trade with Spain and Portugal. Its harbor is perhaps the most motley and picturesque in England, being frequently crowded with Lascars, Creoles, Arabs, &c., and on the arrival of mail-steamers, with Indian and American planters, East Indian nabobs, foreign dignitaries, naval officers, and other British and foreign officials in every variety of costume. In 1880, 9221 vessels, of 1,416,352 tons, entered, and 8838, of 1,344,366 tons, cleared the port. Yacht and ship building and engine-making are actively carried on. S. is also a fashionable resort in summer. It returns two members to the House of Commons. Pop. (1871) 53,741; (1881) 60,235.

S. supplanted the ancient *Clausentum*, which stood about one mile to the north-east, and its foundation is ascribed to the Anglo-Saxons. It is called Hamtune and Suth-Hamtun in the Saxon Chronicle. After the Conquest, S., from which there was ready transit to Normandy, began to prosper rapidly, and in early times it traded with Venice and Bayonne, Bordeaux and Rochelle, Cordova and Tunis. A great part of it was burned by the combined French, Spanish, and Genoese fleets in 1338, and in the following year its defences were strengthened. S. is the birthplace of Isaac Watts (to whom a monument has been erected in the West Park), and of Thomas Dibdin.

SOUTHAMPTON WATER, a fine inlet, stretching north-west from the point at which the Solent and Spithead unite. It is eleven miles long and about two miles wide. The Isle of Wight, which intervenes between the S. W. and the Channel, forms a magnificent natural breakwater, and occasions a second high-water two hours after the first. S. W. receives the Test, or Anton, Itchen, and Hamble.

SOUTH AUSTRALIA. Recent legislation has rendered this name a misnomer, by extending the boundaries of the colony so as to include the entire center of the Australian continent comprised between the Southern and Indian Oceans, and between the 129th and the 141st degrees of E. long.—an area of 914,730 sq. miles.

Character of the Soil, &c.—The northern portion of this vast territory enjoys an abundant rainfall, and is watered by numerous streams and rivers, some of them, as the Victoria and the Adelaide, navigable for a considerable distance by ships of burden. The soil is fertile, and suitable for the cultivation of tropical productions of every description. In connection with the construction of the overland telegraph across the center of the Australian continent, this region has become better known as being suitable for settlement, already commenced.

The great central region opened up by the explorations of Stuart and M'Kinlay, and the country to the north of lat. 33°, may be described as suited only for pastoral purposes, on account of the irregularity of the rainfall and the scarcity of permanent water; and with the exception of a few patches along the coast, the same description will apply to the country to the westward of Gulf of St. Vincent, in 138° E. long. The south-eastern division of the colony, comprised between lat. 33° and the Southern Ocean, and between Gulf St. Vincent and the eastern boundary of the colony, includes every variety of soil, ranging from absolute sterility to the highest degree of fertility, great portion of it being probably unsurpassed by any region in its adaptability both in soil and climate for the growth of wheat, the vine, and the olive. This region is moderately timbered, the principal varieties being the gum, the stringy bark, and the pine, all extremely useful for fencing and building purposes.

Climate.—A country extending over 27° of latitude must necessarily embrace great varieties of temperature; but the climate, owing to prevailing aridity, appears to be, upon the whole, healthy, and remarkably free from epidemic diseases. The average annual mortality during ten years has been found, in the settled districts, to be 15 per 1000 as compared with 22 per 1000 in England. Nearly half of the deaths are those of children. The hottest months are December, January, February, and March. During these months, hot winds occasionally blow. But the same dryness of the air which accounts for the great exaltation of the temperature, renders it more endurable than might at first be supposed, and Europeans are able in the hottest weather to carry on harvest-labor without danger. Careful observations, taken in the agricultural part of the colony (i. e., south of lat. 33°), and extending over a series of years, show the mean temperature during the four hot months to average 73·60°, and during the eight cold months, 56·3°, the extreme range being from 117° to 32°. The rainfall in the north, or purely pastoral district, is as low as 7·947 inches; whilst in the south, or agricultural district, it averages as much as 48·59 inches.

Physical Aspect.—The surface of the country alternates between open plains and wooded ranges of moderate elevation, which enclose many beautiful and fertile valleys. The principal ranges are the Flinders range, which trends northward from the east coast of Spencer Gulf to the neighborhood of Lake Torrens, in lat. 30°, where it branches out into numerous spurs; and the Mount Lofty range, running nearly parallel with Gulf St. Vincent from its head-water in lat. 34° to its termination at Cape Jarvis. The Mount Lofty ranges rise to a height of about 2600 feet, running about north-east and south-west, having a breadth of over 15 miles. This district abounds in picturesque scenery, the summits being well wooded and the slopes of great beauty and fertility, affording eligible building-sites, and producing in the highest perfection many English fruits and vegetables, which fail to thrive on the hotter and more arid soil of the plains.

Throughout S. A., the deficiency of running water is remarkable; in fact, for nearly 1200 miles, following the indentations of the coast from the western boundary of the colony to the estuary of the Torrens, in Gulf St. Vincent, not even a brook of permanent fresh water finds its way into the sea. To the eastward, this deficiency is to some extent compensated, partly by the streams which take their rise in the Mount Lofty range, the principal of which are the Torrens, the Onkaparinga, the Gawler, and the Sturt, but mainly by the Great Murray. See AUSTRALIA, VICTORIA.

Unfortunately for the complete utilization of this magnificent stream, its embouchure in long. 139° E. is exposed to the full force of the Southern Ocean, which, meeting the current, throws

up a shifting bar, rendering the entrance from seaward dangerous, and practicable only for steamers drawing under 7 feet. To counteract this drawback, a tramway has been constructed from Goolwa, connecting the river with Victor Harbor, a small but well-sheltered haven situated in Encounter Bay. Another railway connects North-West Bend, 150 miles up the river, with Port Adelaide; while a northern extension runs to Terowie, 140 miles inland.

Divisions, towns, &c.—The colony naturally falls into three sections—South Australia proper, Central Australia, and the Northern Territory. The 36 counties serve for electoral purposes; the most important division is into districts, of which there were 112 in 1882. Besides Adelaide, the capital, with its 38,000 inhabitants, Glenelg had in 1881, 2724; Burra, 2647; Kapunda, 2290; and Gawler, 1811. Port Adelaide (pop. 3013), 7½ miles from the capital, is the chief harbor; but there are several excellent minor ports.

Mineral Wealth, &c.—The mineral wealth of S. A. is great, the principal metals being copper, lead, and iron; the last is of the finest quality, but in the absence of coal, cannot be profitably worked. There were 12 copper-mines at work in 1880, the principal being the Burra-Burra and the Kapunda, to the north-east of St. Vincent Gulf; the Wallaroo and Moonta, on York's Peninsula. Four gold-fields were being worked in 1880; and mineral oil and marble have been found in paying quantities.

Colonization.—The country, the conformation and physical conditions of which we have above described, was selected in 1837 as the site on which to test what was then a new principle in colonization, known as the Wakefield Theory, from the name of its author, Edward Gibbon Wakefield. The principle may be expressed in a single sentence thus: 'The waste lands of the crown, though entirely valueless prior to the application of labor and capital, acquire value according as these elements of wealth are applied to them in due proportions or otherwise; and the proceeds of the sale of these lands, if properly administered, will suffice to defray the cost of transporting the labor required for their cultivation, at the same time relieving the mother-country from the pressure of able-bodied pauperism.' A second and scarcely less important problem in economic science was put to the test on the same occasion—viz., 'The future revenues of a new colony, supplemented, if necessary, by a lien upon the lands, afford a basis of credit available for raising funds adequate to defray the cost of outfit and first settlement, and therefore the appropriation of the taxes of this country for such purposes is unnecessary and inexpedient.' Owing partly to an unfortunate delay in putting the first settlers in possession of the lands which they had paid for, but mainly to a monopoly by the government of the labor imported by the purchase-money of those lands, production was retarded during the first three years of the settlement; and the necessaries of life, which, but for this mistaken policy, might have been produced on the spot in profuse abundance, had to be imported at enormous cost, and paid for out of capital, by which means the colony was reduced to the verge of bankruptcy.

In 1841, the sound principles to illustrate which the colony was founded, were, for the first time, allowed to come into play. Government interference with the labor-market ceased; and within three years from this change of policy, breadstuffs and other agricultural products were exported from S. A. in such quantities as to glut the markets which previously supplied her necessities. From that date, the progress of the colony, notwithstanding the attractions of the adjacent gold-fields, has been remarkable. The traveler may drive for many hundreds of miles over excellent roads, amidst corn-fields and vineyards cultivated by yeomen proprietors. S. A. has become the granary of the Eastern settlements; and the subjoined statements, compiled from statistics published by government, exhibit a degree of prosperity probably unsurpassed in any country or in any age.

The waste lands are disposed of in fee-simple by public auction at the upset price of 20*s.* per acre, and lands once passed the hammer, may be purchased at that price without further competition. For pastoral purposes, lands are granted to the first applicant for a lease of 14 years at an almost nominal rent. The system of free selection within certain surveyed districts now obtains in S. A., whereby land to the amount of 640 acres can be purchased on credit, at the ordinary upset price, on a written application to the Land-office, and on the signing of an agreement, of which the main conditions are—the immediate payment of 10 per cent. of the purchase-money, and its payment in full in six years, or optionally, of half, on further interest on the remaining half, and the full payment in ten years; personal occupancy of the land; and the executing of improvements to the value of 7*s.* 6*d.* per acre before the end of the third year, and of 10*s.* before the end of the fourth.

Land, open to the public for one year, without being sold, may be leased in blocks of not more than two square miles for twenty-one years, with the right of purchase at the upset price during the lease. Under an act known as the Torrens Act, the difficulties, delays, and expenses attendant on the English system of conveyancing are removed, and land is rendered as easy of transfer, mortgage, and settlement as property in shipping. The great advantages secured by S. A. under this act have caused it to be adopted throughout the Australian colonies.

Government, &c.—The Legislative Council and the House of Assembly are both elective. Members to the Council are chosen by electors with a low property franchise, for a period of 12 years; 6 members retire every 4 years. Members of the Assembly are elected by universal suffrage for 3 years. Voting for both houses is by ballot. The executive government is dependent on parliamentary majorities, as in England. No pecuniary aid is given by government to any religion, and all churches are placed on a footing of perfect equality. The system of education is modelled on the Irish national system. Attendance is compulsory.

In 1881, the population of S. A. was 279,865; in 1876, it was 213,271, besides 3593 aborigines in the settled districts. The imports for 1880 were of the value of £5,581,497; and the exports, £5,574,505. The exports consisted chiefly of corn, wool, and copper. In the same year, the total export of breadstuffs, grain, &c., amounted in value to £2,469,720; wool weighed 43,390,566 lbs., of the value of £1,716,171; and copper 79,730 tons, valued at £346,147. The revenue derived principally from the sale of crown lands and customs dues, amounted in 1881 to £2,010,681; the expenditure, to £1,979,425; and the public debt spent in reproductive works, to £11,196,400. In 1881, the land under cultivation amounted to 2,574,489 acres, of which 1,733,542 were wheat; 13,074 barley; 4355 oats; 4337 vineyards; 4406 peas; 5587 potatoes: 10,212 gardens and orchards. There were 148,219 horses, 283,315 horned cattle, and 6,443,904 sheep in the colony in 1881. Including lines approaching completion, S. A. had in 1880, 821 miles of railway. The proposal to carry a line across the continent from Port Augusta to Port Darwin, has been favorably received. The colony has an extensive system of electric telegraphs. An overland line constructed at the expense of the S. Australian government, and opened in 1872, runs from Adelaide to Port Darwin, across Central Australia, a distance of 2000 miles, and through junction with the Anglo-Indian line, connects Australia with all the great centers of civilization. The places of worship in the colony in 1880 numbered upwards of 850. The number of schools in 1880 was given as 370; scholars, 40,578; teachers, 837. See an elaborate descriptive work on the colony, *South Australia*, by William Harcus (1876); Silver's *Handbook to A.*; and the annual issue of the *Australian Handbook*.

SOUTH BEND, a city of Indiana, U. S., on the south bank of the St. Josephs River, near the border of Michigan, on the Southern Railway, 85 miles east of Chicago. It contains a handsome court-house, the Catholic university of Notre Dame, Female Academy and Convent, Northern Indiana College, bank, 2 newspapers, 6 churches, and large manufactories. Pop. (1870) 7206; (1880) 13,280.

SOUTH CAROLINA. See CAROLINA, SOUTH.

SOUTHCOTT, JOANNA, a curious specimen of the religious visionary, was born in Devonshire, England, of humble parentage, about 1750. In her youth she was a domestic servant, chiefly in Exeter; joined the Methodists, and becoming acquainted with a man named Sanderson, who laid claim to the spirit of prophecy, made similar pretensions herself. She received encouragement from some weak-minded clergymen of the Church of England. In 1792, she declared herself to be the woman driven into the wilderness, the subject of the prophecy in Rev. xii. She gave forth predictions in prose and verse, and although very illiterate, wrote numerous letters and pamphlets, which, as well as her prophecies in verse, or rather in doggerel, were published, and found many purchasers, and many received her pretensions as genuine. One of her productions was the *Book of Wonders*. She also issued sealed papers to her followers, which she termed her *seals*, and which, she assured them, would protect them from the judgments of God both in this and the other world, assuring their salvation.

Thousands of both sexes received them with implicit confidence, among whom were men of good education and respectable position in society. At length she imagined herself to have symptoms of pregnancy, and announced that she was to give birth, at midnight on the 19th October, 1814, to a second Shiloh, or Prince of Peace, miraculously conceived, she being then more than 60 years of age. The infatuation of her followers was such that they received this announcement with devout reverence, prepared an expensive cradle, and spent considerable sums, that all might be suitable for so great an occasion. The expected birth did not take place, but on 27th December, 1814, the woman died. On a post-mortem examination, it was found that the appearance of pregnancy which had deceived others, and perhaps herself, was due to dropsy. She was privately buried in London. Her followers, however, were not to be undeceived, and continued to believe that she would rise again from her 'trance,' and appear as the mother of the promised Shiloh. In 1851, according to the census

returns, there were still four congregations of Southcottians in England. Unfortunately, later census returns afford us no information on such subjects. Some passages in her absurd prophecies are of rather a practical character, as the following: 'I am the Lord thy God and Master: Tell I—— to pay thee five pounds for expenses of thy coming up to London; and he must give thee twenty pounds to relieve the perplexity of thy handmaid and thee, that your thoughts may be free to serve me the Lord, in the care of my Shiloh.' This was published in 1820. The Lord is also made to inform his people somewhere, anxious to go to meet the Shiloh at Manchester, that traveling by the new cut is not expensive.

The history of Joanna S. herself has not much in it that is marvelous; but the influence which she exercised over others may well be deemed so, and the infatuation of her followers is hard to be understood, particularly when it is considered that some of them were men of some intelligence and of cultivated mind. Probably the secret of her influence lay in the fact that the poor creature was in earnest about her own delusions. So few people in the world are really so, that they are always liable to be enslaved by others who have convictions of any kind, however grotesque. On her deathbed, Joanna said: 'If I have been misled, it has been by some spirit, good or evil.' She knew that she was not 'herself' (as the Scotch say), when she prophesied; but she was of too mean an order of intelligence to understand that she was mad, and therefore preferred to attribute her delusions to the Deity, or as she said at the last moment with pathetic half-penitent vacillation, to 'some spirit, good or evil.' Poor Joanna never suspected that the spirit which played such vagaries was her own.

SOUTHERNWOOD. See ARTEMISIA.

SOUTHEY, ROBERT, was born 12th August 1774, at Bristol, in which city his father was a linen-draper. In 1788, he was sent to Westminster School by his maternal uncle, the Rev. Herbert Hill, chaplain to the English factory at Lisbon, who undertook the charge of his education, his father's pecuniary affairs having become much embarrassed. At Westminster, he much distinguished himself; but in 1792 a trivial insubordination led to his expulsion; and next year he was entered at Balliol College, Oxford, with a view to his taking orders. This, however, he ultimately declined to do, having been led by his sympathy with the French Revolution, into a considerable departure from the orthodox civil and religious standards. In 1794, he left Oxford, having published the year before, in conjunction with his friend Robert Lovell, a small volume of poems, the first literary venture of a life thenceforward to be almost wholly devoted to literature. Shortly after, he received from Cottle, for his first poem of any length, *Joan of Arc*, the sum of £50; and in November 1795, he was married to a Miss Fricker of Bristol; Coleridge, with whom he had become intimate, on the same day marrying a sister. After passing some little time with his uncle in Portugal, engaged in a diligent study of the language and literature of that country and of Spain, he became a student of Law at Gray's Inn. Here he worked at his new poem of *Madoc*, and learned nothing whatever of law, a pursuit which he speedily relinquished as hopeless. In 1801, he accepted a situation as secretary to Mr. Corry, Chancellor of the Exchequer for Ireland; but finding its duties distasteful to him, he very soon threw it up, and finally betook himself to literature as his sole source of livelihood.

In 1804, he settled himself at Greta Hall, near Keswick in Cumberland, where he spent the remainder of his life, working with the regularity of a machine, happy in his family relations and his unremitting daily round of congenial, though continuous toil. His biography thence onward for forty years, till the pen dropped from his fingers, might be summarized in the list of his works, which of itself would fill a page or two. In addition to these formal publications, he wrote largely for various periodicals, notably for the *Quarterly Review*, to which, from its establishment in 1809—having now become as violently conservative in his views as in youth he had been revolutionary—he was a most constant and valued contributor.

In 1807, in consideration of his services to literature, a pension of £160 per annum was awarded him; and in 1813, on the death of Mr. Pye, he succeeded him as Poet Laureate. Through Sir Robert Peel, in 1835, he received a further pension of £300, and along with it the offer of a baronetcy, which, however, he decided to decline. His first wife dying in 1837, he, two years after, was married to Miss Caroline Bowles. On March 21, 1843, he died, his few last years having for the most part been passed in a state of painful mental stupor, which incapacitated him for literary exertion.

S.'s poetry—except in a few of his shorter ballad pieces—can at no time be said to have been popular, and is now nearly forgotten. His chief works are *Madoc*, *Thalaba*, *The Curse of Kehama*, and *Don Roderick*, of which the last two are reckoned the best. In all of them are to be found noble passages, in which an ample and stately rhetoric counterfeits with surprising success the pure instinct of music; but they rather skilfully illustrate the art and technic of poetry than breathe its essential life. As a prose writer, he ranks high; his style is easy, lucid, agreeable, nicely modulated throughout, and readily rising into eloquence on suggestions of sentiment and subject. But of all his multifarious writings in this kind, his little *Life of Nelson* seems most likely to survive as a classic. The most popular of his works when produced, it continues to be admired as, within the assigned limits, an almost perfect model of biography. Other very excellent biographies, however, are those of the poet Cowper, of Bunyan, and Wesley. His Life and Correspondence, edited by his son, was published in 6 vols. (1849); a Selection from his Letters (1856); his *Correspondence with Caroline Bowles* (1881).

SOUTH ISLAND, the southern of the two large islands which, with the small Stewart's Island, form the British colony of New Zealand (q. v.).

SOUTHMO'LTON, a municipal borough in the north of Devonshire, 11 miles east-south-east of Barnstable. Woollen goods are manufactured. Pop. (1871) 3978; (1881) 3340.

SOU'THPORT, a fashionable bathing-place in Lancashire, on the south shore of the estuary of the Ribble, 19 miles north of Liverpool. It is a handsome town, and is almost wholly of recent erection. There are assembly-rooms, libraries, large hotels, &c.; the sands are good, and there is an iron pier nearly a mile long. The rapidity with which S. has risen in public favor as a watering-place, is the best evidence of its salubrity and beauty. Pop. (1851) 5391; (1881) 32,164.

SOUTH SEA SCHEME, THE, commonly designated the SOUTH SEA BUBBLE, a term peculiarly expressive of its hollow and ephemeral splendor and sudden collapse, was originated by Harley (q. v.), Earl of Oxford, in 1711, with the view of restoring public credit, and providing for the extinction of the floating national debt, which at that time amounted to £10,000,000. This debt was taken up by a number of eminent merchants, to whom the government agreed to guarantee for a certain period the annual payment of £600,000 (being 6 per cent. interest), a sum which was to be obtained by rendering permanent a number of import duties. The monopoly of the trade to the South Seas was also secured to these merchants, who were accordingly incorporated as the 'South Sea Company,' and at once rose to a high position in the mercantile world. The wondrously extravagant ideas then generally current respecting the riches of the South American continent, were carefully fostered and encouraged by the Company, who also took care to spread the belief that Spain was prepared, on certain liberal conditions, to admit them to a considerable share of its South American trade; and, as a necessary consequence, a general avidity to partake in the profits of this most lucrative speculation sprung up in the public mind.

It may be well to remark in this place, that the Company's trading projects had no other result than a single voyage of one ship in 1717, and that its prominence in British history is due entirely to its existence as a purely monetary corporation. Notwithstanding the absence of any symptoms of the carrying out of its great trading scheme, the Company had obtained a firm hold on popular favor, and its shares rose day by day; and even when the outbreak of war with Spain in 1718 deprived the most sanguine of the slightest hope of sharing in the treasures of the South Seas, the Company continued to flourish. Far from being alarmed at the expected and impending failure of a similar project—the Mississippi Scheme (q. v.)—the South Sea Company believed sincerely in the feasibility of Law's scheme, and resolved to avoid what they considered as his errors. Trusting to the possibility of pushing credit to its utmost extent without danger, they proposed in the spring of 1720, to take upon themselves the whole national debt (at that time £30,981,712), on being guaranteed 5 per cent. per annum for 7¼ years, at the end of which time the debt might be redeemed if the government chose, and the interest reduced to 4 per cent.

The directors of the Bank of England, jealous of the prospective benefit and influence which would thus accrue to the South Sea Company, submitted to government a counter-proposal; but the more dazzling nature of their rival's offer secured its acceptance by parliament—in the Commons by 172 to 55, and (April 7) in the Lords by 83 to 17; Sir Robert Walpole in the former, and Lords North and Grey, the Duke of Wharton, and Earl Cowper in the latter, in vain protesting against it as involving inevitable ruin. During the passing of their bill, the Company's stock rose steadily to 330 on April 7, falling to 290 on the following day. Up till this date, the scheme had been honestly promoted; but now, seeing before them the prospect of speedily amassing abundant wealth, the directors threw aside all scruples, and made use of every effective means at their command, honest or dishonest, for keeping up the factitious value of the stock. Their zealous endeavors were crowned with success; the shares were quoted at 550 on May 28, and 890 on June 1. A general impression having by

this time gained ground that the stock had reached its maximum, so many holders rushed to realize, that the price fell to 640 on June 3. As this decline did not suit the personal interests of the directors, they sent agents to buy up eagerly; and on the evening of June 3, 750 was the quoted price. This and similar artifices were employed as required, and had the effect of ultimately raising the shares to 1000 in the beginning of August, when the chairman of the Company and some of the principal directors sold out. On this becoming known, a widespread uneasiness seized the holders of stock, every one was eager to part with his shares, and on September 12 they fell to 400, in spite of all the attempts of the directors to bolster up the Company's credit.

The consternation of those who had been either unwilling or unable to part with their scrip, was now extreme; many capitalists absconded, either to avoid ruinous bankruptcy, or to secure their ill-gotten gains, and the government became seriously alarmed at the excited state of public feeling. Attempts were made to prevail on the Bank to come to the rescue by circulating some millions of Company's bonds; but as the shares still declined, and the Company's chief cashiers, the Sword-blade Company, now stopped payment, the Bank refused to entertain the proposal. The country was now wound up to a most alarming pitch of excitement; the punishment of the fraudulent directors was clamorously demanded; and parliament was hastily summoned (December 8) to deliberate on the best means of mitigating this great calamity. Both Houses, however, proved to be in as impetuous a mood as the public; and in spite of the moderate counsels of Walpole, it was resolved (December 9) to punish the authors of the national distresses, though hitherto no fraudulent acts had been proved against them. An examination of the proceedings of the Company was at once commenced; and on Walpole's proposal, nine millions of South Sea bonds were taken up by the Bank, and a similar amount by the East India Company. The officials of the Company were forbidden to leave the kingdom for twelve months, or to dispose of any of their property or effects. Ultimately, various schemes, involving the deepest fraud and villainy, were discovered to have been secretly concocted and carried out by the directors; and it was proved that the Earl of Sunderland, the Duchess of Kendal, the Countess Platen and her two nieces, Mr. Craggs, M.P., the Company's secretary, Mr. Charles Stanhope, a Secretary of the Treasury, and the Sword-blade Company, had been bribed to promote the Company's bill in parliament by a present of £170,000 of South Sea stock.

The total amount of fictitious stock created for this and similar purposes was £1,260,000, nearly one-half of which had been disposed of. Equally flagrant iniquity in the allocation of shares was discovered, in which, among others, Mr. Aislabie, the Chancellor of the Exchequer, was implicated. Of these offenders, Mr. Stanhope and the Earl of Sunderland were acquitted, through the unworthy partiality of the parliament; but Mr. Aislabie and the other directors who were members of the House of Commons, were expelled; most of the directors were imprisoned, and all of them suffered confiscation of their possessions. The chairman was allowed to retain only £5000 out of £183,000 and others in proportion to their share in the fraudulent trapsactions of the Company. At the end of 1720, it being found that £13,300,000 of real stock belonged to the Company, £8,000,000 of this was taken, and divided among the losers, giving them a dividend of 33⅓ per cent.; and by other schemes of adjustment, the pressure of loss was so fairly and widely distributed, that the excitement gradually subsided. Contemporary with this great gambling scheme were numerous other 'bubbles,' most of them based upon the most shadowy foundations, and projected for the achievement of the most frivolous and even absurd ends; but none of them rose to such importance as the South Sea Scheme, though collectively they added greatly to the general distress of the period, till they were suppressed by act of parliament, 12th July 1720.—See Coxe's *Walpole*, *Bubbler's Medley*, published by Carrington Bowles, Mackay's *Popular Delusions*, and the various histories of England during this period.

SOUTH SHETLANDS, New, a group of islands in the South Atlantic, about 600 miles S. of Cape Horn, in lat. 61°—63° 50′ S. The islands are destitute of vegetation, with the exception of a species of moss. The chief are Smith, Livingston, Nelson, King George, Clarence, and Elephant Islands. Ice and snow lie at the sea-level all the year.

SOUTHWARK. See London.

SOUTHWELL, a small market-town of considerable antiquity in Notts, 12 miles north-east of Nottingham. At S., Charles I. surrendered himself to the Scotch commissioners. S. has a noble minster, Norman and Early English in style; a church was built here by Paulinus in 627. An act of parliament in 1878 provided for founding a new bishopric at S., when certain conditions (as to endowment, &c.) should have been fulfilled. Pop. (1871) 2400.

SOUVALKY, chief town of the government of the same name, in Poland, on the left bank of the river Charnagarche, a tributary of the Niemen, 538 miles S.W. of St. Petersburg. Pop. (1880) 21,040.

SOUZDAL, a town of Russia, in the government of Vladimir, is one of the oldest towns in Russia, dating, it is said, from 606 B.C. Pop. (1880) 9000.

SO'VEREIGN, the name applied in politics to the person or body of persons in whom the legislative power of a state is vested. In limited monarchies, sovereignty is in a qualified sense ascribed to the king, who, though the supreme magistrate, is not the sole legislator. A state in which the legislative authority is not trammeled by any foreign power, is called a sovereign state. The states of the German Emplre were designated *mi-souveraines*, because their sovereignty was qualified by their subordination to the imperial authority; and the same term may be applied to the states of the American Union.

SOVEREIGN, an English gold coin of the value of twenty shillings sterling, the standard weight of which is 123·374 grains troy. The name was first applied to a gold coin issued in the reign of Henry VIII., otherwise called the double royal or rial, on which the king was represented in the royal robes. The name disappeared after a few reigns, and was revived as applicable to the gold piece of George III., issued in 1817, of the value of twenty shillings, which was substituted for the guinea, which had previously been current, of the value of twenty-one shillings.

SOWBREAD. See Cyclamen.

SO'WERBY BRIDGE, a small manufacturing town in the West Riding of Yorkshire, three miles south-west of Halifax. It contains iron-works, malting-houses, corn-mills, worsted and cotton factories, chemical works, and dye-works; but the woollen manufacture is the principal branch of industry. Pop. (1871) 7041; (1881) 8721.

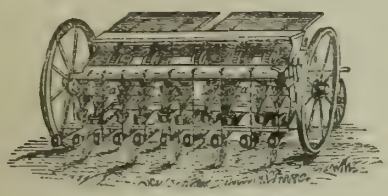
SOWING and SOWING-MACHINES. Sowing is the deposition in the ground of the *seeds* of cultivated plants, and while agriculture was yet in a rude condition, was always performed by scattering the seeds from the hand over the prepared surface of the soil. This mode, distinguished as *hand-sowing*, is still employed in the Highlands and in garden husbandry; but in the more extensive operations of the farm, it has been very much superseded by the use of sowing-machines of various kinds—the broadcast sowing-machine, the drilling-machine, and the dibbling-machine; the first being employed exclusively for cereals and grasses, the other two for any kind of crop. The preparation of the soil for the reception of the seed consists in the thorough removal from it, or destruction, of weeds; in its reduction to as fine a state of division as possible by means of the plough, grubber, harrow, and roller, and in the application of the fitting manures. Attention must also be paid to the seed to be sown, that it be mature, unmixed, and each seed perfect in itself. A frequent change of seed from different soils and climates is beneficial. Strong, vigorous seed should be used. Imperfection of seed can be remedied by 'steeping' the seed previous to sowing it.

The 'steeps' employed are of two sorts, acid and alkaline; the former acting directly on the fungoid sporules and the bruised grains, and destroying their vitality; the latter converting the oily matter which attaches the sporules to the grains into soap, and so detaching them by the aid of a little stirring. Of the acid steeps, blue vitriol or sulphate of copper (SO_3,CuO + 5HO) in the proportion of ¼ lb.—1 lb. to as much water as will cover 4 bushels of grain, is the best of all steeps, and is the one most commonly employed; the others are green vitriol or sulphate of iron (SO_3, FeO + 7HO), and various arsenical preparations. The alkaline steeps, which are inferior to the former, being more limited and less certain in their action, are putrid urine, lime-water of maximum strength, and Glauber's Salts or sulphate of soda. After the seed had been steeped, it ought to be spread out on a floor in thin layers to dry, after which it should be at once sown.

Cereals.—As above mentioned, cereals may be sown either broadcast, drilled, or dibbled. If the first method is to be adopted the land receives what is called the seed-furrow; or if rough, it gets a single stripe with the harrows, and the seed is then sown either by hand or by the broadcast machine. This machine consists of a triangular frame with the apex to the front, supported on three wheels, and carrying a long wooden box of the form of a triangular prism, set with a flat side—the lid—uppermost. This box, which is placed at right angles to the line of draught, is furnished with a row of small holes, at the bottom, about 7 inches apart; and a little above this row is placed a longitudinal spindle, carrying a set of hard circular brushes, one opposite each hole, and deriving a rotatory motion from the axle of the hind wheels.

The size of the apertures can be adjusted to the desired quantity of seed per acre, by means of a movable plate outside provided with holes corresponding to those of the box. When the box is supplied with seed, and the machine set in motion, the grain drops through the holes, which are kept from clogging by

the rapid rotation of the brushes. The box is made of such a length (16 to 20 feet) that 30 to 35 acres may be sown in a day. The seed is then covered by harrowing. This machine was much used in Scotland, being rather better suited to hilly and uneven surfaces, and from its more rapid execution, to a climate which more frequently interferes with agricultural operations. In England, where the climate is more favorable, and the surface more level, the drilling-machine is the favorite. So it is now in Scotland, where the amount of seed deposited by drilling has increased immensely during the last 10 years. Even in the far inland glens, drill-machines are rather growing in popularity. The land is prepared for sowing by as complete pulverization as possible, and its surface is made quite even by the harrow and roller. The drill (fig.), which in the arrangement of some of its essential parts



Corn-drill.

corresponds to the broadcast-machine, differs from it in being furnished with a set of coulters, which are hollowed behind to enclose the lower ends of a corresponding set of tin tubes, whose upper ends are fixed opposite to the holes in the seed-box.

By this machine, a series of furrows of uniform depth are made by the coulters; into these furrows the seed is conveyed by means of the tin tubes. The modern drill machine covers the seed most uniformly. The harrowing is generally completed before drilling begins. The spindle inside the seed-box is provided with grooved cylinders or pinions in place of brushes, and the seed-rows are generally made from 4 to 10 inches apart. The advantages of this machine over the former consist in the greater regularity of deposition of the seed, which admits of hoeing and other cleaning operations during the early period of growth; in the uniform depth at which the seed is planted, so that none of it is lost by being buried, while it is all covered; in the protection of the operation from the disturbing influence of winds; in the saving of seed and greater yield of grain, it being often found that if drilled seed be to broadcast, in quantity, as 2 to 3, their respective yields are nearly as 5 to 4; in the free access of sun and air during growth; and in the less liability of the crop to 'lodge' flat at the root. But it has one disadvantage: an ordinary drill cannot sow more than 10—12 acres per day, and employs more men and horses than the broadcast-machine. From 2 to 3 bushels of seed per acre suffices with the drill, whereas from 3 to 4 is necessary with the broadcast-machine, and from 5 to 6 bushels with the hand. The great saving of seed and other advantages thus fully atone for the extra work involved by the drill.

The third method of sowing, by dibbling, is employed chiefly on the light soils in the south of England, and even there not generally, at least in the case of cereals, so that a minute description of the machines by which the operation is effected is unnecessary. Suffice it to mention that dibbling only requires about one-third of the seed which is necessary in drilling, and presents still greater opportunities for weeding and stirring the soil in the early stages of growth; but is attended with various important defects, and is more expensive.

When a cereal crop is to be followed by grass, the grass seeds are sown a few days after the other crop, by a broadcast-machine or by the hand.

Beans.—The sowing of this crop (see BEAN) is performed by means of the *bean harrow*, a machine the same in structure as the drilling-machine for corn, but wanting the coulters, and having only three tubes, through which the seeds fall. Peas are frequently sown along with beans, the latter acting as a support to the former, and the two together better preventing the growth of weeds. The hand is also sometimes adopted.

Turnips.—For this crop the ground must be more thoroughly cleaned and broken down than for any other; after which it is formed into drills from 26 to 29 inches apart, which are then supplied with manure, and covered with the drill-plough, splitting the original drills. The new ridges thus formed being directly above the manure, the seeds are sown on the top of each ridge by means of the *turnip-drill*. This machine, instead of a seed-box of the ordinary form, has two tin or tinned-iron barrels, placed on a spindle. Each cylinder has a row of holes round its middle circumference, the row being covered by a circular sliding collar of thin metal, perforated with corresponding holes. Each seed-box has its corresponding seed-tube and hollow coulter, as in the corn-drill; but the turnip-machine has in addition a roller in front of the coulters, for compressing the crests of the ridges, and some machines have two light rollers attached behind, which slightly compress the earth raised by the coulters, and cover the seeds. The quantity of seed sown is about 2 lbs. of globe or yellow, and about 3 lbs. of Swedish turnips to the acre. The proper time to sow swedes is from the 12th to 25th of May, and yellows from the 26th May to the 12th June.

SOW THISTLE (*Sonchus*), a genus of plants of the natural order *Compositæ*, suborder *Cichoraceæ*, having an imbricated involucre, swollen at the base, with two rows of unequal scales, which at length bend inwards; a naked receptacle; the fruit transversely wrinkled and without a beak, the pappus hairy and without a stalk. The COMMON S. T. (*S. oleraceus*) abounds in Britain and in most parts of Europe, as a weed in gardens and cultivated fields. It is an annual plant, delighting in rich soils, grows to the height of two or three feet, with somewhat branching stem, and small yellow flowers almost in umbels. The tender tops and leaves are much used in the north of Europe as greens.—The CORN S. T. (*S. arvensis*) is a perennial with large yellow flowers, frequent in corn-fields in Britain, and throughout great part of Europe.—Nearly allied to the genus *Sonchus* is *Mulgedium*, to which belongs the ALPINE BLUE S. T. (*M. alpinum*), the beautiful blue flowers of which adorn some of the most inaccessible spots of the mountains of Switzerland and of Scotland.

SOY is a thick and piquant sauce, made from the seeds of the SOY BEAN (*Soga hispida*), a plant of the natural order *Leguminosæ*, suborder *Papilionaceæ*, so nearly allied to the genus Dolichos (q. v.) as to be often included in it. It is a native of China, Japan, and the Moluccas, and is much cultivated in China and Japan. It is also common in India, although, probably, not a native of that country. The seeds resemble those of the Kidney Bean, and are used in the same way. The Japanese prepare from them a substance called *Miso*, which they use as butter.

Soy is made by mixing the beans softened by boiling with an equal quantity of wheat or barley roughly ground. The mixture is covered up, and kept for 24 hours in a warm place, to ferment. The mass is then put into a pot, and covered with salt, the salt used being in quantity about equal to each of the other ingredients. Water is poured over it; and it is stirred, at least once a day, for two months, after which the liquor is poured off and squeezed from the mass, filtered, and preserved in wooden vessels. By long keeping, it becomes brighter and clearer. A Chinese sauce, called *Kitjap* (Ketchup), is often sold in Britain as soy, but is very inferior to the true soy.

SPA, a town of Belgium, and a watering-place of world-wide celebrity, stands in a romantic valley amid hills which form part of the Ardennes chain, 27 miles south-east of Liége, and 22 miles south-west of Aix-la-Chapelle by railway. The prettily-built town consists almost entirely of inns and lodging-houses. The chief edifices are the *Redoute*—plain outside, but handsome within, and including under one roof a theater (open four times a week), a ball-room, &c.—and the *Vauxhall*, a second Redoute, but now little used. Gaming, which figured prominently among the amusements, was suppressed in 1872. The mineral springs, seven in number, are all chalybeate, and contain minute quantities of iron, so combined with alkaline salts and carbonic acid gas as to be both easily digested and agreeable to the palate. They are cold, bright, and sparkling, and are efficacious in complaints of the liver, nervous diseases, &c. Spa-water is exported to all quarters of the globe. The other springs are near the town, and most of them are situated amid picturesque plantations. S. is also famed for the manufacture of wooden toys, which are stained brown by being steeped in the mineral waters. Pop. (1870) about 5900. The number of visitors during the season is about 20,000, of whom half are Belgians. S. was frequented as a watering-place as early as the 14th c., and has given its name to many mineral springs.

SPACCAFO'RNO, a city of Sicily, in the province of Syracuse, with 8035 inhabitants. Opposite S., Roger, king of Sicily, gained a signal victory over the Saracens in 1092.

SPACE AND TIME. Space and Time being the most general conditions, forms, or attributes of all existing things, their discussion is linked with the highest problems of philosophy. Space is co extensive with, and inseparable from, the sensible, external, or ObjectWorld; time is a property both of the Object World and of the Subject Mind.

Of the so-called Innate Ideas maintained by one school of philosophy, Space and Time are the foremost examples. (Other examples are Number, Infinity, Being, Substance, Power, Personal Identity, &c.) Accordingly, it is held, on the one side, that these notions are underived, or intuitive to the mind; and, on the other side, that they arise in the course of our education or experience, like our ideas of heat, sound, color, gravity, &c.

To begin with Space. The supporters of the innate or intuitive origin of the idea allow that it does not arise in the mind until actual objects, or extended things, are presented to the senses—until we see the visible, and touch the tangible things around us;

but they declare that this contact with the sensible world is only the *occasion* of our becoming conscious of what was already in the mind. Thus, Mr. Mansel says: 'Space is not properly an *innate idea*, for no idea is wholly innate; but it is the innate element of the ideas of sense which experience calls into consciousness.' It is, in short, the superadding of some independent activity of the mind to the passive sensation.

The reasons usually given for assuming an intuitive element in the idea of Space are, in the main, the reasons given for innate ideas generally; they chiefly resolve themselves into affirming the attributes of *universality* and *necessity* in such ideas, and the inadequacy of mere sensible experience to reveal these high attributes of things. Whatever is got by experience can be thought away; Space and Time cannot. Thus, it is impossible for us to receive any sensible impression of an outward object—the sun, for example—without conceiving that thing as existing in space. To use the language of Kant, Space is a form of our sensibility, or sensible perception; and as the perception itself cannot, he thinks, give this universal and inseparable form—it must be contributed by the mind. Sir W. Hamilton supposes that we may have an 'empirical' notion of Space—i. e., a notion from experience; but that Space as a 'form' is not obtained from experience, but from intuition. He does not, however, explain clearly wherein consists the difference between these two notions.

According to the opposite view, Space is an abstraction from our experience of extended things, exactly as gravity is an abstraction from gravitating bodies, and justice from just actions. We first obtain from experience a variety of impressions, in the concrete, of things possessing extension; and, next, from all these, by the usual process of abstraction, we gain a notion of extension in the abstract, or Space. A few remarks may be made on these two distinct operations, as both involve matters of controversy.

1. Before the Muscular Feelings were distinctly recognized as something superadded to the proper sensations of the senses—or the feelings of mere light, sound, &c., it was not easy to show that, by sensible experience alone, we could perceive objects as extended, or as occupying space. The pure optical sensibility of the eye is for color solely; the pure tactile sensibility is for softness and smartness, roughness and smoothness, &c. When, however, we make full allowance for the whole range of feeling connected with the exercise of muscular energy, there is no difficulty in accounting for the origin of such notions as Resistance (Force or Power) and Extended Magnitude. The element supposed, by the *à priori* philosophers, to be contributed by the mind itself, is, according to the other school, Muscularity, or the feeling of the putting forth of inward energy. The two senses related to our cognizance of Space—Sight and Touch, are compound senses; they involve an active energy, with its peculiar consciousness, as well as a passive sensibility; and all that is characteristic of Extension, or Space, arises through these muscular accompaniments.

2. Having perceived a great number of things as extended, with the intervals of unoccupied extension that separate these, we form an idea of extension in the abstract. The distinguishing peculiarity of this abstraction is related to *unoccupied* extension, or empty space, where we seem to have extension without anything extended; rendering the idea of Space unlike other abstract ideas, as Gravity, or Justice, which are conceivable only as embodied in gravitating things, or just actions. Still, empty space is a reality to us, inasmuch as it expresses cessation of resistance, and free scope for movement. To the senses alone, without the muscular accompaniments, Space would be a nonentity, an inconceivability; but the feeling of the sweep of the arm, or of the locomotion of the body, in passing from one point of resistance to another, is a genuine mental experience—the filling up of the interval between two tactile encounters, or between two optical pictures, with conscious activity.

The idea of TIME, continuance, or endurance, applies both to our feelings of energy put forth, and also to our sensations, emotions, and the flow of our ideas; in other words, it attaches both to the extended or Object World, and to the unextended or Subject Mind. In our muscular feelings, which represent the universe of matter and space, we discriminate a dead strain, or effort of resistance, lasting a short time, from the same strain lasting a longer time; and also a more persisting movement from a less. So in the sensations; a sound enduring a second is different to us from a sound enduring two seconds: a transitory odor is not confounded with one of greater continuance.

We distinguish two bursts of wonder, terror, love, or anger, if they have been unequal in their duration. Abstracting from all these experiences of continuance in the concrete, we obtain the idea of Time; which idea, however, like other abstractions, must be conceived by us under some individual continuing thing. If we were to imagine the whole outward universe annihilated, we should still have, in our own consciousness, an instance of the continuing, and upon that we could sustain the conception of Time. See GENERALIZATION.

Time is measured by Space, and Space by Time. The one is often expressed by the other, but with a certain limitation; we say 'a space of time,' but not a 'time of space.' Movement is common to both. Of passive sensations, the best for indicating time are those of Hearing.

SPADE-HUSBANDRY, COTTAGE-FARMING, AND FIELD-GARDENING, are phrases of synonymous meaning, and denote the cultivation of farm-crops on a small scale by means of the spade. This system has long been in operation in Belgium and Flanders, where the holdings average little more than five, though a few are as large as forty acres; and by steady industry and economy, even the smallest of them is capable of maintaining a family in comfort. In this country, cottage-farming is chiefly practised among the miners in Cornwall, who at first received leases of their coarse unreclaimed land at 2s. 6d.—5s. per acre, the lease to last for three lives. These patches of from three to five acres number over 6000, and have increased greatly in value. In Orkney and Shetland, some of Sutherlandshire, and much of the Western Isles of Inverness and Argyleshire, spade-culture is quite common, and when properly done is a thorough means of cultivation. In Lincolnshire, especially on the isle of Axholme, the same system exists.

The success of small-farming depends on two causes—the inexpensiveness of the stocking and implements, and the superior fertility of the soil when dug. The implements required are—spades and digging-forks of different sizes, hoes, rakes, scythe, reaping-hooks, flail, hayfork, wheel-barrow, and a few other implements equally inexpensive; the steading consists of the cottage, a cow-shed (for one or two cows), and a pig-sty; the stock, of cows, pigs, and poultry, besides household furniture. The superiority of the spade over the plough rests on its deeper cultivation; on its not forming a hard impermeable crust on the surface of the subsoil, as the plough does; on its more thorough subdivision of the soil; and on its more effective burying of weeds. Besides the treading of the land by the horses' feet is avoided. As a conclusive instance of this, may be given a sketch of the system pursued by the Rev. Mr. Smith of Lois-Weedon, Northamptonshire, with its results. Mr. Smith drilled wheat in the usual manner, dug the intervals two spits deep, so as gradually, year by year, to bring up more and more of the subsoil, and by careful keeping down of weeds, repeated stirring of the soil, and sowing the next crop in the intervals between the rows of the former, he succeeded at a total expense of £3, 14*s.* per acre, in obtaining a profit of £8 per acre.

Mr. Smith also sowed wheat in strips of three rows, with twelve inches between the rows, and intervals of three feet between the strips; and by dint of thorough digging and trenching between the rows with the spade, he succeeded for 14 successive years in producing 36 bushels of wheat annually, without the application of a particle of manure. Similar experiments have been made with success at Rothamstead in Herts, by Mr. Lawes, who found, however, that proper and sufficient manuring almost doubled the crop. The subject of cottage-farming deserves serious attention in connection with the movement for ameliorating the condition, and preventing the decrease, of the rural population of the country. It is receiving such; there is a growing feeling among landlords in favor of increasing the number of crofts, and thereby inducing the best laborers to remain in their native country, instead, as has been too much the case, of emigrating.

SPA'HIS (the same with *Sipahi*, or Sepoy, q. v.) were the cavaliers furnished by the holders of military fiefs to the Turkish army, and formed the élite of its cavalry. The S., along with the Janizaries (q. v.), owe their organization primarily to Orchan, the second of the Ottoman sultans, finally to Sultan Amurath I.; and when levied *en masse*, could number 140,000, but such a levy was very seldom called for. In the field, they were divided into two classes, distinguished by the color (red and yellow) of their standards; one class had pistols and carbine, the other a bow and arrows, and both carried a sabre, lance, and *jerid*, or javelin. They were excellent irregular troops; but when European organization was introduced into the Turkish army, they were replaced (1826) by regular horse. At the present time, the French have numerous regiments of Spahis, raised from among the native tribes of Algeria and from France in about equal proportions; the dress, especially of the indigenous soldiers, partakes very much of the Arab character. The natives are allowed to rise to any grade below that of captain; but all the superior officers are of French descent. See ZOUAVES.

SPAIN (Span. *España*), a kingdom of Europe, occupying the larger portion of the great peninsula which forms the south-west corner of the European continent, reaching further south than any other European country, and further west than any except Portugal. It is bounded on the N. by the Bay of Biscay and by France, from which it is separated by the mountain ridge of the Pyrenees; on the

E. and S., by the Mediterranean and Atlantic; and on the W. by the Atlantic and Portugal. Greatest length, from Fuenterrabia on the north to Tarifa on the south, 560 miles; greatest breadth, from Cape Finisterre (Land's End), the extreme point on the west, to Cape Creuze, the extreme point on the east, about 650 miles; average breadth about 380 miles. Area, including the Balearic (q. v.) and Canary Isles, 195,738 sq. m.; pop. (1877) 16,623,384. The country, including the Balearic and Canary Isles, was divided in 1834 into 49 modern provinces, though the former division, into 14 kingdoms, states, or provinces is still sometimes used. The following is a table of the ancient states, and of the modern provinces into which they have been divided, with their areas and populations, according to the census of 31st December 1877:

Ancient Provinces.	Modern Provinces.	Area in Eng. Sq. Miles.	Pop. in 1877.

Coast-line.—The entire perimeter of the country is 2080 English miles, and the coast-line, exclusive of windings, is 1317 miles long, of which 712 miles are formed by the Mediterranean, and 605 miles by the Atlantic. The north coast, from Fuenterrabia west to Cape Ortegal, is unbroken by any considerable indentation. A wall of rocks, varying in height from 30 to 300 feet, runs along this shore; but the water, which retains considerable depth close to the beach, is not interrupted to any unusual extent by islands or rocks. The north-west coast, from Cape Ortegal south to the mouth of the River Minho—which separates the Spanish province of Galicia from Portugal—though rock-bound, is less elevated, and is much more broken than the shores washed by the Bay of Biscay; and the indentations, the chief of which are Noya Arosa and Vigo Bays, form secure and spacious harbors. From the mouth of the Guadiana, on the south, to the Strait of Gibraltar, the coast-line, though well defined, is low, sandy, and occasionally swampy. From Gibraltar to Cape Palos the shores, which are backed in part by the mountain-range of the Sierra Nevada, are rocky and high (though flats occur at intervals), are unbroken by indentations, and comprise only two harbors, those of Cartagena and Malaga. A low, and for the most part sandy, coast extends north from Cape Palos, rising into rocky cliffs and bluffs in the vicinity of Denia, but extending in sandy flats from Denia to the mouth of the Ebro. From the mouth of this river, north to the frontier of France, the coast is alternately high and low, and its principal harbors are Barcelona and Rosas.

Surface and Hydrography.—The compactness and the isolation of this country, and its position between two seas, the most famous, and commercially the most important in the world, are not more in its favor than the character of its surface, which is more diversified than that of any other country in Europe of equal extent. An immense plateau, the loftiest in the continent, occupies the central regions of S., and is bounded on the N. and W. by mountainous tracts, and on the N.-E. by the valley of the Ebro; on the E. by tracts of land frequently low, but in some parts traversed by hill-ranges; on the S. by the valley of the Guadalquivir, which intervenes between it and the Sierra Nevada (q. v.). This great plateau rises to the height of from 2000 to 3000 feet, and occupies upwards of 90,000 sq. m., or about half of the entire area of the country. The whole of the Pyrenean peninsula is divided by Spanish geographers into seven mountain ranges, of which the chief are: 1. The Cantabrian Mountains (q. v.), and the Pyrenees (q. v.), forming the most northern range; 2. The Sierra de Guadarrama, separating Leon and Old Castile from Estremadura and New Castile, and rising in the peak of Penalara 7764 feet above sea-level; 3. The Montes de Toledo, forming a part of the watershed between the Tagus and the Guadiana; 4. The Sierra Morena (q. v.), between the upper waters of the Guadiana and Guadalquivir; 5. The Sierra Nevada (q. v.), running parallel with the shores of the Mediterranean, through southern Murcia and Andalucia, and rising in its chief summits to loftier elevations than are found in any mountain-system of Europe, except that of the Alps. The several mountain-ridges, or as they are called, *Cordilleras* of S., have a general east and west direction, and between them run, in the same direction, the nearly parallel valleys or basins of the great rivers of the country, the Douro, Tagus, Guadiana, and Guadalquivir, each of which is described in its proper place.

Climate and Soil.—The climate of S., owing to the extent and configuration of the country, is exceedingly various. In the north-west (maritime) provinces, it is damp and rainy during the greater part of the year; at Madrid, which is situated about 11° south of London, and only 5° north of the shores of Africa, winters have occurred of such severity, that sentinels, while on duty, have been frozen to death; while the south and east provinces are warm in winter, and are exposed to burning winds from the south, and to an almost tropical heat in summer. Both ancient and modern geographers have adopted difference of climate as the rule for dividing the Peninsula into tracts distinct as well in soil and vegetation as in temperature. Of these tracts or zones the first and most northern may be considered as embracing Galicia, Asturias, the Basque Provinces, Navarre, Catalonia, and the northern districts of Old Castile, and Aragon. In this tract, the winters are long, and the springs and autumns rainy, while north and north-east winds blow cold from the snow-covered Pyrenees. The country, which alternates with hill and dale, is plentifully watered by streams rich in fish, and meadows yielding rich pasturage abound. Corn scarcely ripens in the more exposed districts, but grain crops of all kinds are produced in others, as well as cider, wine, and valuable timber. The middle zone is formed mainly by the great central plateau, and embraces Northern Valencia, New Castile, Leon, and Estremadura, with the south parts of Old Castile and Aragon. The climate of the great part of this region is pleasant only in spring and autumn.

Throughout the chilly winter, the treeless table-lands are overswept by violent tempests, and in summer are burned up by the sun. The soil is generally fertile, and corn and wine are most

abundantly produced. The southern or Bætican zone, comprising the rich country that extends between the southern wall of the central plateau and the Mediterranean shores, includes Andalucia, Murcia, and Southern Valencia. The stony rampart on the north protects it from the chilly winds of the central zone; but it is unprotected against the hot winds (the Solana, see SIMOOM) which in summer blow north from Africa, and render this season intolerable to northern Europeans. Here the winter is temperate, and the spring and autumn delightful beyond description. The descent from the cold and mountainous central regions to this tract of tropical heat and fertility affords a most striking contrast. The soil, which is artificially irrigated, is well adapted to agriculture and the cultivation of heat-loving fruits. The products comprise sugar, cotton, and rice, and the orange, lemon, and date.

Material Revival of Spain; Population; and Distribution of Land.—Owing to a number of causes, S., at one time the most opulent kingdom in Europe, had, in the 18th c., lapsed into a state of complete stagnation; the spirit of enterprise seemed extinct, and ease and squalor to be preferred to labor and affluence. Before the commencement of the present century, however, the country began to throw off its lethargy, and since that time the rate at which it has been advancing toward a healthy condition of active life has become gradually accelerated. Since 1851, the onward movement of the nation has been as rapid as that of any of the great European powers. The population has greatly increased, and is increasing; agriculture, previously stagnant, is now carried on with activity and success; manufactures are multiplying rapidly; and railways, of which, in the beginning of 1848, not a mile had been constructed, are now in process of being laid out between all the great centers of population—over 4000 miles having been completed in 1880. A view of the increase of the population, the first basis of power, will afford an index of the growing prosperity of the country. The estimates of the population of S. for various periods between the beginning of the 16th c. and the middle of the 18th c. vary considerably; but it is certain that there was a gradual decrease of from 2,000,000 to 3,000,000 of inhabitants between the years 1500 and 1700. With regard to later times, we have the following authentic statement:

Year.	Population.
1768	9,159,999
1797	10,541,221
1857	15,464,340
1860	15,673,536
1870	16,835,506

It thus appears that in about a century the population of S. has increased over 7,000,000. Comparing the census of 1870 with that of 1877, we find that the provinces in which the population has most largely increased are Madrid, Barcelona, Cadiz, Valencia, Jaen, Tarragona, Murcia, Avila, Valladolid, and Salamanca. These are for the most part maritime provinces, or such as have railway facilities for communication with the sea. In 1877, there were in Spain one town of near 400,000 inhabitants (Madrid); one of 250,000 (Barcelona); three between 150,000 and 100,000 (Valencia, Seville, Malaga); and three between 100,000 and 75,000 (Murcia, Zaragoza, Granada). In agriculture, as well as in population, the onward movement has been remarkable. The vast mountains of the country affording for the most part only scanty crops of herbage, are utilized as pasture-grounds, and are divided into large farms. But in the warm and fertile plains, especially in localities where water is abundant, the farms are small. Recently it was estimated that there were about 3,426,000 farms of all sizes, of which 750,000 were occupied by tenants, and the others by proprietors. Over 40 per cent. of the whole surface of the kingdom is still uncultivated.

Origin of the People.—The Spaniards are a mixed race, and have sprung from a greater variety of stocks than any other European nation. The bulk of the people is doubtless descended in the main from the ancient Celtiberian occupants of the peninsula. At an early time, however, there were extensive Phœnician and Carthaginian settlements in S., especially on the eastern seaboard. Later, the country was penetrated with Roman elements, and was Romanized throughout, save in the Basque (q. v.) country, where the ancient speech still lives on intact. Gothic invasions left a large Germanic strain in the blood of Spain, which may yet be plainly traced in the hill-country of the north-east. The Arab conquerors of S. planted themselves too firmly on Spanish soil to be utterly expelled; and the Moriscoes (see MOORS) are still, to the number of 60,000, easily distinguishable by their tongue and other peculiarities. In the south and center Gypsies (*Gitanos*) are numerous, and there are some Jews. One result of this commingling of races may be seen in the strongly marked provincial peculiarities of Spain, extending not merely to dialectal differences, but to physique, character, and amusements. The Castilian is the literary language of Spain; the Andalusian diverges somewhat broadly from it; in Catalonia, Valencia, and on the Balearic Isles, the prevailing dialect is closely allied to Provençal; while in the Basque provinces the old tongue is still in universal use among the people. Until lately (see FUEROS), the Basques enjoyed quite peculiar privileges as to local government and administration. In spite of great local differences of character, the Spaniard is generally temperate, and his few wants are easily satisfied. He requires a daily siesta, is not very energetic by nature, loves music, dancing, and the bull-fight, and is not averse to intrigue and the use of weapons. Even amidst poverty and squalor, native dignity never forsakes him. The houses are generally poorly furnished and uncomfortable, and often far from cleanly.

Religion.—Till very lately, the Roman Catholic faith, to which almost all the nation adheres, was the only creed tolerated by law. There are 9 arch-bishoprics, 51 suffragan bishoprics, and 4 unattached bishoprics. Before the suppression of the monasteries in 1836, about one-fifth of the whole nation was engaged in the service of the church.

Occupations of the People.—Agriculturists, laborers, miners, artisans, shepherds, and sailors constitute two-thirds of the population; one-seventh is composed of merchants and tradesmen; another seventh of officials, the army, the nobility, the clergy, nuns, beggars, and prisoners. The nobility is very numerous; the lower nobility, mostly quite poor, counting near 1,000,000 *hidalgos*. Beggars are almost as numerous, owing partly to the large number of benevolent institutions. In 1860 nearly 500,000 persons were maintained in 1028 charitable institutions.

Productions, Commerce, Exports and Imports, &c.—The total imports of Spain, including bullion and specie, in the years 1868—1874, averaged 19 millions sterling per annum; while the exports averaged 12 millions sterling. The countries with which S. trades most extensively are France, Great Britain, Cuba, British possessions, and the United States; and of these countries, Great Britain receives the great bulk of its exports, while France (owing, probably, to the vicinity of that country) supplies more of the imports of S. than any other state. The foreign trade of the country is carried on most extensively at the following ports, which are set down in the order of their importance: Barcelona, Cadiz, Santander, Alicante, Malaga, Valencia, Bilbao, Cartagena, San Sebastian, Elizondo, and Irun. The principal articles imported are, in the order of their importance, raw cotton, timber, wool manufactures, machinery, brandy, coal, dried fish, sugar, iron, linen, mineral oil, cocoa. The value of the wine exported is more than a third of that of the total imports; the chief articles exported are—wine, metals, dried fruit, flour, bullion, green fruits, olive oil, minerals, wool, grain, vegetables and seeds, esparto grass, cork, salt, and live animals. About 5,000,000 gallons of olive oil are annually produced in the country, of which quantity the half is exported.

Between 1870 and 1880, the annual value of the total imports into Spain varied from £15,500,000 to £21,600,000; of the total exports, from £15,700,000 to £23,200,000. In the same period the imports from the United Kingdom ranged from £2,950,000 to £4,070,000; the exports thither, from £7,800,000 to £10,975,000. The annual value of the wine exported varies from £6,000,000 to £9,000,000. Of this Great Britain absorbs from £1,500,000 to £2,800,000 worth—Spain contributing about two-fifths of all the wine imported by Britain.

The cotton manufactures of S. have been making considerable advance, and silk stuffs are largely fabricated. The principal cotton factories are at Barcelona. Excellent paper is made at Tolosa and Valladolid, and in the last-named town there are a few minor manufactures. All the manufactures of tobacco, arms, and gunpowder are carried on by the government exclusively. Though neither the agricultural nor the mineral resources of Spain are properly developed, much progress has been evident of late years, chiefly in mining. Lead, copper, and tin are abundant; quicksilver is wrought; and there are large deposits of good coal and iron ore. The last, however, are so imperfectly worked, that great quantities of iron and coal are imported from Belgium and England.

In 1880, the mercantile marine of Spain consisted of 2031 seagoing vessels (of which 226 were steamers), with a total burden of 596,664 tons. The number of Spanish vessels that entered British ports in 1880 was 797, of 285,166 tons.

Railways and Roads.—In October 1848, the first Spanish railway, 18 miles in length, from Barcelona to Mataro, was thrown open to the public; and by the beginning of 1880, 4067 miles of railway were open for traffic, and in the same year 1242 miles were in course of construction. The Spanish railways are the property of private companies; but in most cases the companies have received extensive 'subventions' from government. The number of letters that passed through the post-office in 1857 was 38,704,788; in 1879, the number of letters and post-cards had increased to 85,210,000. In 1880, there were 9000 miles of telegraphs in operation in Spain.

Army.—The effective of the Spanish army on the peace-footing was, in 1879–80, 90,000 men (of whom 60,000 were infantry, 13,000 cavalry, and 10,000 artillery); not including the *guardia civil, car-*

abineros, or reserve. On the war-footing, the effective is officially stated to comprise 450,000 men.

Navy.—In 1880, the navy consisted of 121 steam-vessels (including 5 ironclads and 11 other men-of-war of the first class) with 525 guns; besides training-ships and vessels for harbor defence.

Revenue and Expenditure.—The entire revenue of S. for the financial year 1879–80, was 778,478,388 *pesetas*, equivalent to about £31,139,135. The expenditure for the same year was 806,590,940 pesetas, or about £32,263,638. The public debt amounted in 1880 to £436,367,240.

Education.—Education is still very backward in Spain, though matters have greatly improved since 1845, when public instruction was first organized. Of the total population in 1860, only 3,130,000 could read and write, and 705,000 could read. In 1870, there were 26,500 public schools, with 1,500,000 pupils; and about 70 *institutos* or upper schools. There are ten universities in S.—in Madrid, Barcelona, Granada, Oviedo, Salamanca, Seville, Santiago, Valencia, Valladolid, and Zaragoza. Of these, five have five faculties, and two have four faculties. The universities are attended by above 12,000 students. There are besides numerous schools of art, of navigation, and mining. There are ten academies or learned societies, and a few large libraries.

History.—S., the *Spania*, *Hispania*, and *Iberia* of the Greeks, and known to the Romans by the same names, was inhabited at the period at which it first receives historical mention, by a people deriving their origin from different races. It is supposed to have been originally inhabited by a distinct race called Iberians; upon whom, however, a host of Celts are supposed to have descended from the Pyrenees. In the earliest times of which we have any record, these two races had already coalesced and formed the mixed nation of the Celtiberians, who were massed chiefly in the center of the Peninsula, in the western districts of Lusitania, and on the north coasts. In the Pyrenees and along the east coast, were to be found pure Iberian tribes, while unmixed Celtic tribes occupied the north-west.

In Bætica (Andalucia) there was a large admixture of the Phœnician element, and on the south and east coasts, numerous Phœnician, Carthaginian, Rhodian, and other colonies. A portion of the south coast, called Tartessus by the Greeks, the Tarshish of Scripture, was much frequented for its mineral riches by the Phœnician merchantmen, and the 'ships of Tarshish' were as distinct a section of the Tyrian mercantile marine, as were the Spanish galleons of the 16th c., or our own Indiamen of more recent times. But the bond which connected the Iberians and the Phœnicians was purely of a commercial character. About the middle of the 3d c. B.C., the Carthaginian influence began to be much felt in Iberia, and a considerable tract of territory was brought under subjection to Carthage by Hamilcar, (q. v.) who founded the city of Barcelona. During the next eight years, the Carthaginian interest was advanced, and its power further strengthened by Hasdrubal (q. v.—died 220 B.C.), son-in-law of Hamilcar, who founded Carthago Nova (the modern Cartagena), and concluded a treaty with the Romans, whereby it was stipulated that he should not advance his standards north of the Iberus (Ebro). Hannibal (q. v.), son of Hamilcar, and the greatest of all the Carthaginian generals, now assumed the command in the peninsula. He attacked and destroyed Saguntum (q. v.), and thus violated the treaty made between his father and the Romans. The destruction of Saguntum was the cause of the Second Punic War, for the principal incidents of which see CARTHAGE, ROME, HANNIBAL, and the SCIPIOS.

After the Romans had driven the Carthaginians from the peninsula in 206 B.C., the country was erected into a Roman province, consisting of two political divisions—*Hispania Citerior* (Hither S.) including the eastern and northern districts, or those nearest to the center of the Roman Empire; and *Hispania Ulterior* (Further S.) including the districts furthest from Rome, or the southern and western districts. It was not, however, till 25 B.C. that the Cantabri and Astures in the extreme north of the country laid down their arms to Augustus. After the country had been reduced to subjection, it was divided into the three provinces of Tarraconensis (embracing the northern and eastern provinces), Bætica (Andalucia), and Lusitania (Portugal and certain of the western provinces). This division of the country lasted till the reign of Constantine the Great (q. v.), (306—337). From the time of the complete supremacy of the Romans till the death of Constantine, the condition of S. was eminently prosperous.

The inhabitants, when brought under the iron rule of the empire, were forced for the time to desist from the intestine wars in which it had been their habit to indulge, and adopting the language, laws, and manners of their conquerors, they devoted themselves to industrial pursuits, and increased remarkably both in wealth and in numbers. Everywhere throughout the country, towns of a purely Roman character sprang up, among the chief of which were Leon, Emerita Augusta (Merida), Pax Julia (Beja), Cæsar Augusta (Zaragoza); and numerous aqueducts, bridges, amphitheatres, &c., were built, the ruins of which are the wonder of the modern traveler.

S., though obtained at enormous cost both in treasure and in human life, was for three centuries the richest province of the Roman Empire. Its fertile fields formed for a considerable time the granary of Rome, and from its metal-veined sierras, an immense amount of treasure in gold, silver, &c., flowed into the Roman coffers. 'Twenty thousand pound-weight of gold,' says Gibbon, 'was annually received from the provinces of Austria (Asturias), Galicia, and Lusitania.' This amount of wealth was not the voluntary offering of the natives, who were compelled to labor in their mines for the benefit of strangers; and thus S., in the early ages, was the type of Spanish America in the 15th and succeeding centuries, with the single difference that in the first case the Spaniards were the slaves, and in the second they were the slaveholders. In 409 A.D., hordes of barbarians, Alans, Vandals, and Suevi, crossed the Pyrenees and swept over and desolated the peninsula—the Vandals for the most part settling in Bætica, the Alans in Lusitania, and the Suevi in Leon and Castile. About 412, the Visigoths invaded the country, and their king, Athaulf, who acknowledged a nominal dependence on the Roman emperor, established the Gothic monarchy in Catalonia. See GOTHS. Of the Visigoths—by whom the Suevi were subjugated (584), the Vandals and Alans expelled (427) from the country, and large portions of Gaul annexed to their Spanish dominion—the most remarkable kings were Wallia (415—418), who greatly extended the Gothic monarchy; Euric (466—483), who, besides increasing his territory, introduced and enforced a body of laws, and did much for the advancement of civilization in S.; Wamba (673—680), who built a fleet for the protection of the coasts; and Roderic (q. v.), who was killed at Xeres de la Frontera in 711, in battle with the Moors.

The battle of Xeres gave the Moors almost undisputed mastery of nearly the whole of S., as well as of the outlying Gothic province of Septimania (Languedoc) in France; for the remnant of the Goths betook themselves to the highlands of Asturias, Burgos, and Biscay, where, in a region which throughout had enjoyed more liberty than any other part of S., they maintained their independence.

Dynasty of the Moors.—The Arabs, or, as they are more properly termed, the Moors (q. v.), held S. for the first few years of their rule, as a dependency of the province of North Africa; but after the downfall of Muza (q. v.), and his son Abd-el-aziz, who had been the deputy-governor of Spain, the country was governed (717) by *emirs* appointed by the calif of Damascus. The favorite scheme pursued by the Spanish emirs was the extension of their conquests into Gaul, to the neglect of the rising power of the Goths in Asturias; they also took the Balearic Islands, Sardinia, Corsica, and part of Apulia and Calabria; the Mediterranean was infested by their fleets, but their northward progress was most signally checked on the plain of Tours by Charles Martel (q. v.). Anarchy and bloodshed were prominent features of the first 40 years of Mohammedan rule in Spain. The *walis*, or local governors of districts and provinces, frequently rebelled against the emir, and drew sword against each other according as ambition or animosity dictated. Within this period of 40 years, no fewer than 20 emirs had been called to the direction of affairs; but a revolution at Damascus, which unseated the Ommiades, and placed the Abbasides in possession of the califate, put an end to this state of misrule in S.

The last of the *emirs*, Jussuf, was in favor of the Abbasides, but the *walis* and *alcaydes* being chiefly of the Ommiade faction, invited one of this family, who was in concealment among the Zeneta Arabs in Barbary, to become an independent calif in Spain. See OMMIADES. Thus was founded the *califate of Cordova*, from which, in 778, the Franks wrested all its possessions north of the Pyrenees, and North-eastern S. to the Ebro; the latter acquisition, subsequently denominated the *Spanish March*, being alternately in the hands of the Moors and dependent upon France.

Christian Kingdoms.—During this period of Moorish domination, the small independent kingdom of Asturias, founded by Pelayo (q. v.), had been growing in power and extent. It was increased by Galicia in 758, and by parts of Leon and Castile towards the close of the century. In 758, a second independent Christian kingdom was founded in Sobrarve, and increased by portions of Navarre on one hand and Aragon on the other, but though it, along with the French Gascons, aided the Moors at Roncesvalles (q. v.), it was, in 801, again swallowed up by the califate of Cordova. However, 36 years afterwards a Navarrese count, casting off his allegiance to France, founded the third Christian kingdom, that of Navarre (q. v.), which from this time easily maintained itself, owing to its situation, in independence of the Moors.

The kingdom of Asturias, now (900) Leon, was for a long time distracted by bitter and bloody strife among the members of the royal line, and with its neighbor Navarre would have fallen an easy prey to the powerful Ommiades, had not the latter directed their chief attention to the subjugation of Morocco; and under

cover of this relaxation of the constant warfare between Moors and Christians, another independent monarchy, an offshoot from Leon, was founded in Castile (933, kingdom in 1035), which from its central position, and consequent greater facilities for expansion, soon became the most powerful of the Spanish states, especially after its union (temporary, 1072—1157), in 1230, with Leon. A considerable part of Aragon had been wrested from the Moors by Sancho III. (1000—1035) of Navarre, and at his death this part of his dominions passed by inheritance to his son Ramiro, who added to it the districts of Sobrarve and Ribagorza, and a considerable extent of country which he conquered from the common enemy, the Moors. This kingdom of Aragon was the last Christian kingdom formed in S.; and though it increased by acquisitions from the Moors, yet being limited by Leon, Castile, and Navarre on one side, and the Spanish March (now only the county of Catalonia or Barcelona) on the other, its princes aimed at maritime power; and by the union, through the marriage of the Count of Barcelona with Queen Petronilla, of the Spanish March with Aragon, means were obtained of carrying out this policy, and the spread of the Aragonese dominion to Sicily (q. v.), Naples (q. v.), and other regions bordering on the Mediterranean, was the consequence.

These three kingdoms—Castile and Leon, Navarre, and Aragon—continued, sometimes in combination and sometimes separately, to war against their common enemy, the Moors—Castile being, from its greater power and proximity, the most persistent assailant, and Navarre, for the opposite reason, the least so; but whenever the arrival of fresh levies from Africa, or the accession of an energetic calif threatened serious danger to any one of the three, the others generally came to its aid.

The extinction of the Ommiades in Spain in 1031, and the disruption of the califate into the minor kingdoms of Cordova, Seville, Toledo, Lisbon, Zaragoza, Tortosa, Valencia, Murcia, Badajos, and seven others of less note, was an occurrence by which the kings of Castile and Aragon did not fail to benefit, for by well-directed and unremitting attacks they subdued some, rendered others tributary, the kings of Portugal also on their side gallantly and successfully pursuing the same policy; and a few years more would have certainly annihilated Moorish domination in S., had not Mohammed of Cordova and Seville, hard pressed by Alfonso VI. of Leon and Castile about the close of the 11th c., applied for aid to an Arab tribe, whose military career in North Africa had been of the most brilliant character. This tribe, the Almoravides—i. e., men devoted to the service of God—had made themselves masters of the provinces of Africa and Almagreb, and founded the empire of Morocco.

Responding to the request of Mohammed, the Almoravides crossed over to S., defeated the king of Aragon and Castile, and recovered much of New Castile. Then, turning upon their ally Mohammed, they compelled him to yield up the provinces of Cordova and Seville, and all the minor Moorish princes to follow his example; so that, in 1094, the Almoravide sovereign was acknowledged sole monarch of Mohammedan Spain. The power of this tribe, however, began to decline about 1130, and was extinguished by the Almohades (q. v.), a fanatical sect of Mohammedans, who landed in S. in the middle of the 12th c., and conquered the territories of the Mohammedans in Spain. During the reign of the third monarch of this dynasty took place the battle between the combined forces of Castile, Leon, Navarre, Aragon, and Portugal, with the Moors, in which the former gained the most celebrated victory ever obtained by the Christians over their Moslem foes, the latter losing, according to the account transmitted to the pope, 100,000 killed and 50,000 prisoners. This sanguinary conflict, fought on the plains of Tolosa (*las navas de Tolosa*), 16th July 1212, broke the Almohade power in Spain, as that of Salamanca (22d July 1812), almost exactly six centuries afterwards, did the more formidable strength of Napoleon.

On the fall of the Almohades, Mohammed-ben-Alhamar, the king of Jaen, rose to the first place among the Mohammedan princes, and founded (1238) the *kingdom of Granada*. The king of Granada was speedily forced to become a vassal of Castile, and from this period all danger from Moslem power was over. The rest of the history of the Spanish kingdoms before their union is undeserving of a detailed account. The Castilian court was the scene of almost constant domestic strifes and rebellions, varied with a campaign against Granada or in favor of the monarch of that kingdom against his rebellious vassals; the only prominent monarchs of this kingdom being Ferdinand III., who confined the Moorish dominion to the south of Andalucia, Alfonso X. (q. v.), Alfonso XI., Pedro the Cruel (q. v.), and Queen Isabella, the last sovereign of Castile, who succeeded her brother Henry IV., owing to a wide-spread belief in the illegitimacy of the latter's daughter. Aragon, on the other hand, was almost wholly free from intestine dissensions, doubtless owing to the interest taken by the Aragonese monarchs in Italian politics; of these sovereigns Jayme I. (1213—1248) conquered Valencia and Majorca, and, first of all the Aragonese kings, received a voluntary oath of allegiance from his subjects; Pedro III. (1248—1285), who obtained Sicily (1282), Minorca, and Iviza; Jayme II., who conquered Sardinia and Corsica; Alfonso V. (1416—1468), who conquered Naples; and Ferdinand II. (q. v.), the Catholic, the last sovereign of Aragon, who, by marriage with Isabella, Queen of Castile, in 1469, the conquest of Granada in 1492, and that of Navarre in 1512, united the whole of Spain (and French Navarre) under one rule.

The year 1492, in the reign of Ferdinand and Isabella, witnessed also the discovery of America, as well as the capture of Granada. S. had now become consolidated into one empire, from the Pyrenees to the Strait of Gibraltar, civil wars were at an end; and a splendid continent, teeming with riches, had been opened up for Spanish adventure and enterprise. But as the most active spirits among the Spaniards now crowded to the New World, the soil of S., and its mineral treasures, both inexhaustible sources of wealth, were neglected for the riches of the fancied El Dorado, where, as was everywhere believed, gold was more plentiful than iron was in the old country. Besides the drain upon the country from emigration, the expulsion of the Jews and Moors was productive of the direst results; and the decline of the splendid Spanish Empire, upon which the sun even then never set, may be said to have had its origin in the event which raised the country to the height of its magnificence. Charles I. (Charles V. of Germany, q. v.) succeeded Ferdinand, and in his reign Mexico (q. v.) and Peru (q. v.) were added to the possessions of Spain. Philip II. (q. v.), by his enormous war expenditure and mal-administration, laid a sure foundation for the decline of the country. Industry, commerce, and agriculture may be said to have been extinguished at the expulsion of the Moriscoes (see MOORS); and the reigns of Philip III. and Philip IV. witnessed a fearful acceleration in the decline of S. by the contests with the Dutch, and with the German Protestants in the Thirty Years' War, the intermeddling of Olivarez (q. v.) in the affairs of Northern Italy, the rebellion of the Catalans, whom the minister wished to deprive of their liberties, the wars with France, and the rebellion of Portugal (1640), which had been united to S. by Philip II. That of Charles II. was still more unfortunate, and the death of the latter was the occasion of the War of the Spanish Succession (see SUCCESSION, WAR OF).

Philip V. (q. v.) was the first of the Bourbon dynasty who occupied the throne of Spain. Under Charles III. (1759—1788), a wise and enlightened prince, the second great revival of the country commenced; and trade and commerce began to show signs of returning activity. During the inglorious reign of Charles IV. (1788—1808), who left the management of affairs in the hands of the incapable Godoy (see ALCUDIA), a war (1796—1802) broke out with Britain, which was productive of nothing but disaster to the Spaniards, and by the pressure of the French another arose in 1804, and was attended with similar ill success. Charles abdicated in favor of his eldest son, the Prince of Asturias, who ascended the throne as Ferdinand VII. Forced by Napoleon to resign all claims to the Spanish crown, Ferdinand became a prisoner of the French in the year of his accession, and in the same year Joseph, the brother of the French emperor, was declared king of S. and the Indies, and set out for Madrid, to assume the kingdom thus assigned to him. But before this time, an armed resistance had been organized throughout the whole country. The various provinces elected juntas or councils, consisting of the most influential inhabitants of the respective neighborhoods, and it was the business of these juntas to administer the government, raise troops, appoint officers, &c. The supreme junta, that of Seville, declared war against Napoleon and France on the 6th of June 1808.

In July, England, on solicitation, made peace with S., recognized Ferdinand VII. as king, and sent an army to aid the Spanish insurrection. Joseph, on July 9, entered S., defeated (through his lieutenant Bessières) the Spaniards at Rio Seco, and entered Madrid on the 20th; but the defeat of Dupont at Baylen by the veteran Spanish general Castaños, somewhat altered the position of affairs, and Joseph, after a residence of ten days in his capital, was compelled to evacuate it, and retire north to Vitoria. The noble defence by Palafox of the city of Zaragoza against Lefebvre, and the return of the Marquis de la Romana with 7000 regular troops who had been wiled from the country by Napoleon, did much to inspirit the patriots. On the 12th July 1808, Sir Arthur Wellesley, afterwards Duke of Wellington (q. v.), at the head of the British auxiliary force, landed (5th August) at Mondego Bay, and began the Peninsular War by defeating the French at Roliza and Vimiero (q. v.); but in spite of his opposition, the Convention of Cintra was signed, and the French transported to their own country. In November 1808, Napoleon, who had been preceded by Ney (q. v.) with 100,000 men entered S., and at once assumed the command. For a time his armies were completely successful; Soult utterly routed the Spanish general Belvedere, 10th November, and annihilated Blake at Reynosa on the 13th. Castaños and Palafox were routed at Tudela by Lannes, and in the beginning of December, Napoleon entered Madrid.

At this time, the British forces were under the command of Sir John Moore (q. v.), who, aware of his great inferiority in numbers and resources, retreated west from Salamanca, whither he had come to assume the command of the allied forces, and reached Coruña (q. v.) on the 11th January 1809. On the 22d April General Wellesley arrived in Portugal, and, at once commencing operations, drove Soult from Oporto, and took possession of Portugal; then, favored by the disunity of action which subsisted between the three or four French armies who held S., he directed his attacks upon the army of the center, retreating when any of the others came to its aid, and by dint of masterly generalship and bold enterprise, succeeded, after four campaigns, in driving the French from the country. To this result, the co-operation of the Portuguese and of the Spanish *guerrillas*, the revengeful hatred of the peasantry towards their tyrannical oppressors, and the drafts from the Spanish armies so frequently made by Napoleon for his wars in Central Europe, largely contributed. See WELLINGTON, SOULT, VICTOR, &c. Napoleon, loath to lose his hold of the Peninsula, sent Soult, his most trusted general, to stop the ingress of the British into France; but the battles of the Pyrenees (24th July—1st August 1813), and of the Nivelle, Orthez, and Toulouse, in the beginning of 1814, brought to a victorious conclusion this long and obstinate contest.

In 1812, a constitution, on the whole liberal, had been devised for the country by the Cortes of Cadiz. It was, abrogated, however, by Ferdinand VII. (q. v.), who treated the subjects who had shown such devoted loyalty to him with infamous ingratitude, and obtained the aid of France to establish despotism. The reign of his daughter, Isabella II. was disturbed by the Carlist rebellion in 1834—1839, in which the British aided the queen with an army under Sir De Lacy Evans. See CARLOS. The next event of importance was the contest between Espartero (q. v.), the regent, and the Queen-dowager Christina, for the supreme power during the minority of the queen. Espartero was successful from 1840 to 1843, but was compelled to flee before O'Donnell and Narvaez, and was not restored till 1847. The constituent Cortes of 1837 drew up a new constitution, based on that of Cadiz. In 1845, another constitution was promulgated by Narvaez (q. v.), Duke of Valencia. Frequent changes of ministry, occasional revolts, the banishment of Queen Christiana (1854), the formation of the O'Donnell ministry (1858), the war with the Moors (see MOROCCO), the annexation of St. Domingo in 1861, and the quarrels between S. and her former colonies, Peru (1864—1865) and Chili (1865), were the most marked events in the more recent history of Spain prior to 1868. In 1868, Isabella was driven from the throne by a general revolt, and the Cortes, in Nov. 1870, elected Prince Amadeo of Italy to be king. Finding the task of ruling constitutionally hopeless, Amadeo abdicated early in 1873, upon which the form of government was changed into a republic. During the remainder of 1873, and the whole of 1874, S. was the scene of general anarchy and much bloodshed, resulting from the mutual opposition of the Carlists and Republicans. On Dec. 31, 1874, Alphonso, son of the ex-Queen Isabella, was declared king of S. at Santander.

SPA'LATO (often erroneously called SPALATRO; in Illyric, SPLIT), an important seaport of Dalmatia, empire of Austria, is finely situated on a promontory on the eastern coast of the Adriatic. It originated in the famous palace of Diocletian, built in the 3d century. As this immense structure (which occupied twelve years in building) stood not far from the city of Salonæ, the great bulwark of Roman power in Dalmatia, it was called *Salonæ Palatium*, briefly written *S. Palatium*. When Salonæ was conquered by the Avars in the 7th c., the inhabitants fled for refuge to the fortress-palace of the emperor, where they laid the foundations of a new town, corruptly named *Aspalathum* whence the modern *Spalato*. Even yet, more than one-half of the town is compressed within the limits of the ancient palace, a considerable portion of whose walls still remain. The best-preserved parts of the palace are the temple of Jupiter, transformed in the 7th c. into a Christian cathedral, and the temple of Æsculapius, which is now a Baptistery dedicated to St. John. Modern S. is divided into an old and new town; the former consisting mainly of narrow, crooked, and dirty lanes; the latter more agreeable and open. It is the seat of a bishop, has a chamber of commerce and manufactures, and is the principal emporium for goods passing from Italy overland into Turkey. Pop. (1869) 12,000.

SPA'LAX. See MOLE-RAT.

SPA'LDING, an important market-town and river-port in Lincolnshire, on the Welland, 8 miles from its mouth in the Wash. Considerable trade is carried on by the Welland, and vessels of 100 tons are able to reach the town. An important stock and corn market is held every Tuesday. A newspaper is published weekly. S. was a place of consequence as early as the Saxon times, and contained a Benedictine monastery. Pop. (1881) 9260.

SPALLANZANI, LAZARO, a celebrated anatomist and naturalist, was born at Scandiano, in Modena, Italy, 12th January 1729. After a careful education he took clerical orders; and in 1754, he was appointed to the chair of Logic, Metaphysics, and Greek at Reggio; but soon after this he obtained a chair at Modena, and refusing the tempting offers made him by the universities of Parma and Coimbra, and the Academy of St. Petersburg, gave himself up to the study of natural history. His attention was directed to the doctrine of generation propounded by Needham and Buffon, which, after careful study and experiment, he overturned. He then turned his attention to the circulation of the blood, and was the first to follow its course through the intestinal tube, the liver, spleen, ventricles, pulmonary organs, &c.; 'established,' according to Senebier, 'the propulsive power of the heart over the blood in the various vessels, demonstrated that the heart never wholly empties itself, explained the various causes which retard the circulation, and the obstacles produced by the weight of the blood.'

On the re-establishment of the university of Pavia, S. was appointed (1768) Professor of Natural History, and keeper of the museum, which he greatly enriched with fishes, crustacea, and testacea, the fruits of his numerous excursions. In 1785, refusing the chair of Natural History at Padua, which had been so admirably filled by Vallisnieri, he accepted the proposal of the Archduke Ferdinand to accompany, with doubled salary, the Austrian ambassador to Constantinople (22d August 1785); and during a residence of 11 months in Turkey, found ample materials for study and observation. In 1788, he visited Naples whilst Vesuvius was in eruption, the Lipari Isles, and Sicily, in restless prosecution of his scientific labors, and then retired to Pavia, where, refusing the tempting offers of the French Directory, he spent the remainder of his life, prosecuting his scientific researches amid bodily sufferings, and died of apoplexy, 12th February 1799. His works, many of the more valuable of which have been translated into English, are too numerous to mention; but a complete catalogue of them, along with a biography, will be found in the *Biographie Médicale*, vol. vii. See also, for the result of his labors, the *Eloge*, by M. Alibert, in the *Mémoires de la Société Médicale d'Emulation*.

SPAN, a natural measure of length, being the distance between the tips of the thumb and middle finger, the hand being stretched as much as posible. This space averages about 9 inches, and the term came to denote a measure of 9 inches.

SPA'NCELLED, in Heraldry, a term applied to a horse two of whose legs are fettered by a log of wood.

SPA'NDAU, a town of Prussia, in the province of Bradenburg, is situated at the confluence of the Havel and Spree, 9 miles west-north-west of Berlin. S. is an important fortress; has a citadel (besides other fortifications) surrounded by water, with a garrison of upwards of 3000 men, and is a military dépôt. S. carries on manufactures of arms, gunpowder, woollens, &c., and has an active transit-trade as a station on the Berlin and Hamburg Railway. Pop. (1880) 29,311. It is one of the oldest towns in the Middle Mark of Bradenburg, and was long the residence of the Kurfürists of the Hohenzollern House.

SPA'NDREL, the triangular space between the outside of an arch and a square head including it. This space is often filled with sculptured foliage, figures, &c.

SPA'NGLES, small circular pieces of very thin metal, usually silvered or gilded tin, pierced with a needle-hole, so that they can be sewed on to cloth. They are chiefly used for decorating theatrical dresses.

SPA'NIEL, a kind of Dog, of which there are many breeds, differing considerably in size and other characters. None of the spaniels are large; some are amongst the smallest of dogs. Some are used for sporting purposes, others are merely kept as pets and companions. All of them are lively, playful, docile, and affectionate in a high degree. The S. is ever petitioning for regard, and shows boundless joy on receiving marks of kind attention. The ENGLISH or SUSSEX S. is of elegant but moderately stout form; with very large pendant ears, of which the hair is very long; the muzzle rather broad; the tail bushy; the body covered with long silky hair; the colors various, very often liver-colored and white, or red and white. The name S. is said to indicate the introduction of this kind of dog into England from Spain. In the days of falconry, spaniels were much used for starting the game. The Cocker (q. v.), the Springer (q. v.), and the Blenheim Dog (q. v.) are different kinds of Spaniels. The KING CHARLES'S S. is a beautiful black and tan breed, almost as small as the Blenheim dog, and derives its name from Charles II., who took great delight in dogs of this kind. The WATER S. is one of the larger breeds. It has comparatively hard hair, and is distinguished by its readiness te pursue game by swimming. It is much used in decoy-ponds to drive ducks into the net.

SPANISH GRASS. See PAPER.

SPANISH LANGUAGE AND LITERATURE. The Spanish language is one of the Romanic tongues, and, like the others, originated in the *lingua Romana rustica*. See ROMANIC LANGUAGES. The earliest of the different Spanish dialects that assumed a literary form was the Castilian, which gradually became, and has continued to be, the classic dialect of the nation. It finely blends a certain soft, lingering richness of cadence with an occasional sonorous majesty of expression, and on the whole may be considered one of the most beautiful of the European tongues. The course of Spanish conquest has also led to its establishment in Mexico, Central America, Cuba, Porto Rico, the greater part of South America, the Canary Isles, and the Philippines. See the *Grammar and Dictionary* published by the Spanish Academy (1771), the grammars of Keil (Leip. 1837), Fuchs (Berl. 1837), Wiggers, and Schele de Vere (New York, 1854). The best material for a historical grammar is furnished by Diez in his *Grammatik der Romanischen Sprachen*. The best Spanish dictionaries, besides that of the Academy, are Cabrera's (Mad. 1837), the Spanish-German by Seckendorff (3 vols., Hamb. 1823), and the Spanish-English of Neumann and Baretti (re-edited by Velazquez, New York, 1852).

Literature.—The literature of Spain may, in a superficial sense, be regarded as commencing under the auspices of the Romans, for Lucan, Seneca, and other eminent Latin authors were at least Spanish by birth; and, if we please, we may further look upon the Christian ecclesiastical writers of the Gothic period as the second link in the historical chain. But in the proper sense of the term, the literature of these two periods is no more *Spanish*—i. e., national—than an English book by an Anglo-Indian is to be held as a portion of Hindu literature, or the sermons preached by a missionary to South Sea Islanders are to be quoted as specimens of the literature of the Pacific. Passing over, then, the various developments of non-national literature in Spain—pagan Latin, ecclesiastical Latin, Arabic and Jewish—we come down to the 12th c., and then, for the first time after the gradual formation of a Spanish language, begin to notice the growth of something like a Spanish literature Epic and didactic poems appear, written in Castilian verse, and full of strong national sentiment. The oldest of these is the *Poema del Cid* (see CID CAMPEADOR), of which only a single MS. exists. This MS. contains three other poems: *The Book of Appollonius, Prince of Tyre; The Life of Our Lady, St. Mary of Egypt;* and *The Adoration of the Three Holy Kings*, the authorship of which (as of the *Poema del Cid*) is unknown. Other productions of this *first* period are the rhymed *Lives of the Saints*, by Gonzalo of Berceo (died about 1260); and the anonymous poem, *Count Fernan Gonzalez*, which, like the *Poema del Cid*, paints the earnest and picturesque struggle between the Moors and Spaniards. In all of these, we trace the influence either of the church or of the chivalric poetry of France; but they maintain, nevertheless, a distinctively national and independent character.

A great impulse was given to the artistic development of Spanish literature by Alfonso the Wise of Castile (q. v.), who substituted Spanish for Latin in the courts of law, and fostered in many ways the growth of the national language. He is regarded as the founder of Spanish prose, his chief work in this department being the compilation of a series of codes, of which the most memorable is *Las Siete Partidas*, and a translation of the Bible into Spanish. Subsequent princes walked in his steps, and achieved an honorable reputation both as authors and patrons of literature, conspicuous among whom was the Infante Don Juan Manuel (died 1347), whose *El Conde Lucanor* (Count Lucanor) is a collection of 49 tales, apologues, &c., from oriental sources, and wearing an oriental aspect. The most remarkable Spanish poet of the 14th c. is Juan Ruiz, arch-priest of Hita (died 1351). His pieces, composed in a great variety of measures, number some 7000 verses, and include religious and love songs, fables, pastorals, &c. The didactic tendency is particularly visible in the *Danza general de la Muerte* (Dance of Death).

The *second* period of Spanish literature embraces the later portion of the middle ages, and is marked by the presence of lyric poetry in considerable quantity, alongside of the didactic. It seems to have been inspired by the strains of the Provençal poets settled at the court of the Counts of Barcelona, and always continued to be more courtly than national. The most complete collection of this lyric poetry is the *Concionero general* of Fernando del Castillo (Valencia, 1511; 10th edit., 1573), which contains the names of 136 authors, among which may be mentioned those of the Marquis of Villena, and the Marquis of Santillana, the three Manriques, Macias, Sanchez de Badajoz, Alonso de Cartagena, Diego de San Pedro, and Fernan Perez de Guzman. Against this court-poetry, however, a strong reaction took place, the national spirit reasserting itself vigorously in ballads, chronicles, romances of chivalry, and the drama. The best collection of the ballads (about 1000 in all) is to be found in the *Romancero general* (13 vols., 1605—1614); of the Chronicles (half-genuine, half-fabulous narratives of ancient Spanish heroes), the best are those of Ayala, of Juan Nuñez de Villaizan, the *Chronicle of the Cid*, and the *Chronicle of the Travels of Ruy Gonzalez de Clavijo;* of the romances of chivalry, the most celebrated is the *Amadis de Gaul*, parent of innumerable others (see AMADIS); and of the drama, among the first specimens are the pastoral plays of Juan de la Enzina, and the *Celestina* of Fernando de Rojas.

The *third* period, extending from the 16th to the 18th c., is the most splendid and productive in the annals of Spanish literature. Under Charles V., Spain became the foremost state in Europe, and the conquest of Naples brought it into close relation with the literature of Italy. The great Italian masters, such as Dante and Petrarch began to be studied, and Italian measures and poetic forms to be imitated, although the rich, strong Spanish spirit is never lost. The first of this new school was Juan Boscan Almogaver (died 1543), a brilliant sonneteer; other members of the same school are Garcilaso (q. v.) de la Vega, Diego Hurtado de Mendoza (q. v.), Francisco de Saa de Miranda, and Jorge de Montemayor (author of the once famous pastoral novel of *Diana*, see NOVELS), Fernando de Herrera (q. v.), and Luiz de Leon (died 1591), the last two of whom rank as the two greatest lyric poets that Spain ever produced. Gradually, a national drama established itself too. Conspicuous names in this department are Villalobos, Perez de Oliva and Naharro (about 1517), sometimes regarded as the father of the Spanish drama. The last-mentioned wrote his comedies in the favorite national measure, the *redondillas*, and divided them into three acts. Besides these, we must mention Lope de Rueda, Juan de la Cueva, and Geronimo Bermudez, who cultivated tragedy with success. Among the most eminent prose writers of the first section of this third period was Geronimo Zurita, author of *Annales de la Corona de Aragon* (Annals of the Crown of Aragon, 6 vols.)—a somewhat critical work, showing a decided advance on the credulous chronicles of the monks; Oliva, whose *Dialogo de la Dignidad del Hombre* (Dialogue on the Dignity of Man) is a fine specimen of elegant literature; and Morales, author of *Discursos* (Essays), relating to practical philosophy; &c.—Cervantes (q. v.) marks, if not exactly a new era, at least a splendid outburst of Spanish genius.

It is unnecessary here to criticise the productions of his genius; we may only note, as it were, historically the fact, that his immortal *Don Quixote* put an end to the romances of chivalry—or rather to the extravagant imitations of these that sprung up after the age of chivalry had passed away. Lope de Vega (q. v.), a contemporary of Cervantes, and Calderon (q. v.), gave the national drama a European renown, and had, especially the latter, a host of followers more or less celebrated, among whom are Francisco de Rojas, Agustin Moreto, Fragoso, Diamante, Antonio Hurtado de Mendoza, Juan de la Hoz, Antonio de Solis, and Agustin de Salazar y Torres. The lyric and 'epic' poets of this period, which embraces the second half of the 16th, and the whole of the 17th c., are innumerable, but not great. The most notable names are those of the brothers Argensola, and Alonso de Ercilla y Zuñiga (author of *Araucana*, a fine poem on the conquest of Araucania in Chili by the Spaniards). A peculiar form of the novel also appeared, called the 'rogues' novel,' of which the only memorable specimen is the *Guzman de Alfarache* of Mateo Aleman; and even it derives not a little of its importance from the fact that it suggested Le Sage's *Gil Blas*. In history, the most distinguished names are those of Mariana (q. v.) and Solis.

The *fourth* period of Spanish literature extends from the accession of the Bourbons (1701) to the present time, and was long marked (like the contemporary literature of Germany) by a servile imitation of French models, and these by no means the best of their kind. This literary ascendency of France in the first half of the 18th c. over all civilized Europe is a very curious phenomenon, worthy of closer study than it has yet received. The most notable of the Frenchified Spaniards was Ignacio de Luzan, whose *Poetica* (1737) is a thoroughly Gallican performance. His efforts to denationalize the literature of Spain were combated by Garcia de la Huerto and others, and at length a sort of compromise was effected, and the 'Salamanca School' emerged into notice. Its founder, Melendez Valdez (born 1754), was a man of high genius, who subordinated his liberal culture to the sovereign control of a patriotic inspiration, and the same qualities are visible in its other members—Iglesias, Noroña, Quintana (q. v.), Cienfuegos, Arriaza, and Gallego. The great Peninsular War, and the subsequent political movements in Spain, had a powerful effect in stirring up anew the elements of nationality, and the present century can show a lengthened list of names both in prose and poetry. We can only afford space for a few: Tapia, Maury, Juan Bautista Alonso, Jacinto de Salas y Quiroga, Espronceda, Serafin Calderon, Zorrilla, Hartzenbusch, R. de Campoamer, Santos Lopez Pelegrin, Villergos, and G. Gomez de Avellaneda, in poetry; Saavedra, Mora, Zorrilla Gregorio Romero y Larrañaga, Manuel de Santa Ana, in romantic fiction; Leandro, Fernandez Moratin, in the drama; Ulloa, Muñoz, Capmany, Ferreras, Quintana, Navarrete, Clemencin, Torreno, and Maldonado, in history; Jovellanos, Arguelles, Miñano, Marina, Donoso Cortes, Martinez de la Rossa, &c., in political oratory.

Spain has not as yet achieved great results in any departments of science, either physical, mental, or moral; but of late years she has turned her attention seriously to scientific studies, and several admirable treatises in jurisprudence, political economy, medicine, philosophy, philology, and geography have been produced.—See Bouterwek's and Sismondi's *Histories of Spanish Literature;* and above all, Ticknor's work on the same subject (3 vols., New York, 1849—1854), which has been translated into Spanish.

SPANISH MAIN (i. e., *main-land*), a name generally given during the 16th c. and the earlier part of the 18th to the north-east coast of South America, from the Orinoco to the Isthmus of Darien; as also to the contiguous southern portion of the Caribbean Sea, traversed by the Spanish treasure-ships. The name occurs very frequently in connection with the history and exploits of Buccaneers (q. v.).

SPA'NISH TOWN, the seat of government of the British possession of Jamaica (q. v.), on the right bank of the Cobre, and 10 miles west of Kingston. It contains several important public institutions, is ill-built and unhealthy, and contains about 6000 inhabitants.

SPA'NKER, a large quadrilateral sail, with parallel sides, set between the gaff and boom of a ship. Its foreleech is attached by rings to the mast. The spanker is a fore-and-aft sail of great importance in bringing the vessel to the wind.

SPAR (Ger. *Spath*), a term used by miners to denote any bright crystalline mineral, and which has been adopted by mineralogists in the names of a number of minerals, as calcareous spar, fluor spar, &c., in which, however, it has no proper generic significance.

SPA'RIDÆ, a family of acanthopterous fishes, having a general resemblance to the perch family—a single dorsal fin, which is not protected by any scales, and of which the anterior rays are spinous, the pectoral and ventral fins sharp-pointed, the tail-fin notched; the gill-cover shining, without proper spines or denticulations; the palate destitute of teeth; the scales large, broader than long, and generally thin. There are several sections of the family, distinguished by the teeth, which in some are all small and card-like, whilst others have trenchant, conical, and round molar teeth, variously arranged. The greater number inhabit the seas of the warm parts of the world; many species are found in the Mediterranean; a few on the coasts of Britain. Among the British species are the Gilthead (q. v.), and several species of different genera, known by the common name of Sea Bream (q. v.). The S. are generally good for food, and some are highly esteemed. Among them are the *Sargus* of the Mediterranean (*Sargus Rondeletii*, much valued by the ancient Romans, and the Sheep's Head (*Sargus ovis*) of the North American seas, which commands a very high price in the New York market.

SPARKS, JARED, American historian, was born at Willington, Connecticut, May 10, 1789; graduated at Harvard University in 1815; became tutor in mathematics and natural philosophy, and one of the conductors of the *North American Review*. In 1819, he was settled as a Unitarian minister at Baltimore, when he wrote, *Letters on the Ministry, Ritual, and Doctrines of the Protestant Episcopal Church*. In 1821, he established a periodical called the *Unitarian Miscellany and Church Monitor*, in which he first published his *Letters on the Comparative Moral Tendencies of the Trinitarian and Unitarian Doctrines*. In 1823, he edited six volumes of essays and tracts on theological subjects, and, abandoning the pulpit, became for seven years sole editor of the *North American Review*. In 1828, he published a *Life of John Ledyard, the American Traveler;* and from 1834 to 1837, edited at Boston, 12 octavo volumes of the *Writings of George Washington*. This important national work was followed by the *Diplomatic Correspondence of the American Revolution* (12 vols. 8vo, Bost. 1829—1830), and the *Life of Gouverneur Morris* (3 vols. 8vo. Bost. 1832). At this period, he commenced the *American Almanac of Useful Knowledge*, and began also his *Library of American Biography*, first issued in two series of 10 and 18 vols. 18mo. In 1840 was published his collection of the *Works of Benjamin Franklin* (10 vols. 8vo), after which he visited Europe to collect materials for his *Correspondence of the American Revolution* (4 vols. 8vo, 1854). He also wrote, in 1852, two pamphlets in answer to Lord Mahon, on the *Life of Washington*. Besides these multifarious literary labors, combining laborious research with clear arrangement, a simple style and accurate statement, he filled, from 1839 to 1849, the M'Lean chair of history, and from 1849 to his departure for Europe in 1852, that of President of Harvard University. S. died March 15, 1866.

SPA'RROW (*Passer* or *Pyrgita*), a genus of birds of the family *Fringillidæ*, having a strong conical bill, the upper mandible slightly curved, the lower mandible compressed and shorter than the upper, the nostrils partly concealed by the short feathers at the base of the bill, the legs moderately long and stout, the claws sharp and curved, the tail moderately long, and nearly even at the tip. The species are not very numerous, and are exclusively found in the Old World. The COMMON S., or HOUSE S. (*P. domesticus*), plentiful everywhere in the British Islands, and too well known to require description, is found also throughout Europe, abounding particularly in the northern countries, from which its range extends eastwards into Siberia, and southwards to the north of Africa and of India. Of all British birds, the S. is the boldest in its approaches to man. Town sparrows are not mere visitors from the neighboring country, but constant inhabitants of the town itself, with the smoke of which their plumage is begrimed. The S. in its best plumage is not a very beautiful bird, nor has it such elegance of form as many others of the finch tribe; it has no melodious song, but its habits are interesting, and its frequent lively chirp pleasing. Sparrows often congregate in great flocks, particularly in autumn, when they find rich supplies of food in the ripened grain.

The S. is one of the most omnivorous of birds. Animal and vegetable food seem equally acceptable to it. During summer, vast numbers of insects and their larvæ are devoured by sparrows, and in this way they make amends for their plunder of the grain in autumn, which they begin as soon as it is sufficiently ripened, and continue as long as there are sheaves in the field. Their depredations have induced many farmers to use means for their destruction. They are good to eat, though little used for this purpose in Britain. It is otherwise in France, where all the small birds are sought after as articles of food. But the destruction of sparrows may be carried too far; and in France it has been followed by an increase of caterpillars, vastly more injurious to crops than the sparrows themselves. The S. makes a very inartificial nest, collecting a quantity of hay, or some similar material, in a hole of a wall, and lining it with feathers; sometimes, but more rarely, building a rude dome-shaped nest in the higher branches of a tree. Apart from the habitations of man, which it so much frequents, it often builds in crevices of rocks, or in cliffs on the sea-coast, or under the shelter of the nests of rooks, one rook's nest sometimes covering several nests of sparrows. Several broods are produced in succession, and the breeding season is prolonged over the whole summer, one brood succeeding another.

The summer plumage of the S. is more brilliant than that of winter, and the female is of more sober plumage than the male, exhibiting indeed almost no variety of color.—The TREE S. (*P. montanus*), the only other British species, is very similar to the Common S., but of rather smaller size. It is also a widely distributed bird, frequent over great part of the old World. It is rarely seen in towns.—In Italy, the Common S. is rare to the south of Piedmont; and another closely allied species (*P. cisalpina*), takes its place, very similar in its habits as well as in its characters.—In America, there are numerous species of *Fringillidæ*, popularly known as sparrows, of which the WHITE-THROATED S. (*Zonotrichia albicollis*) is most nearly allied to the true sparrows. The nostrils are in a small groove, and the tail is slightly forked.—The HEDGE S. (q. v.) is a bird very different from the true sparrows.—The name S. is popularly given in different parts of the world to many different birds, chiefly *Fringillidæ*.—The bird called S. in the English translation of the Bible is a species of thrush.

SPARROW-HAWK (*Accipiter* or *Nisus*), a genus of *Falconidæ*, ranked among the *ignoble* birds of prey (see FALCONIDÆ and FALCONRY). The bill is curved from the base, short, and compressed; its upper ridge rounded and narrow; the cutting margin of the upper mandible with a distinct festoon. The wings are short; the legs long, slender, and smooth. Only one species is British—the COMMON S. (*A. nisus*, *A.* or *N. fringillarius*), a small hawk, only about twelve inches in length, a considerable portion of the length belonging to the tail. It is found in almost all parts

Sparrow-hawk (*Accipiter nisus*).

of Britain, and in Asia as far south as Bengal, and as far east as Japan. It is not found in America. It very often makes its nest in the deserted nest of a crow. It is a bold, active bird, very destructive to poultry and pigeons. The S. has often been trained for the purposes of falconry, to take land-rails, patridges, and similar game. The S. of Australia (*A. torquatus*) is marked by a collar of numerous bars of white. Its habits are very similar to those of the European sparrow-hawk.—The American S. (*Falco sparverius*), common in most parts of the United States, is similar in size to the European S., but is rather allied to the kestrel.

SPA'RTA, anciently LACEDÆMON, the capital of Laconia, and the most famous city of Peloponnesus, occupied partly a range of low hills on the right bank of the Eurotas, and partly the intervening plain. Its appearance, even in its palmiest days, was by no means equal to its renown, for, though not destitute of handsome public buildings, the severe law ascribed to Lycurgus, that 'the doors of every (private) house should be fashioned only with the saw, and the ceiling with the axe,' exercised a cramping influence on the development of architecture and of the fine arts generally. The natural defences of the place, or, at least, of the long valley of Lacedæmon, in which S. stood, were so great, that it continued unfortified down to the Macedonian period—nearly a century after its mighty struggle with Athens for the hegemony of Greece; and, indeed, it was not regularly fortified till the time of the tyrant Nabis (195 B.C.). Previous to the Dorian conquest, the primitive Achæans of S. seem to have dwelt in four or five scattered hamlets.—These hamlets were welded into one city, so to speak, by the conquerors, and became known as town-districts. The Acropolis of S. occupied a hill in the northern part of the city, and was adorned with a temple to Athena (the tutelary goddess of S.), plated with bronze, whence it was called the Brazen House, and the goddess herself *Chalcioecus* (the Dweller in the Brazen House). On the bronze plates were beautifully sculptured various Greek myths.

At the eastern base of the Acropolis stood the Agora or Marketplace, whence streets proceeded to the different quarters of the city. Here stood the public buildings of the magistrates. The Agora contained many statues. The principal street in S., called the Aphetais, ran south from the Agora to the southern wall, through the most level part of the city, and was lined with a long succession of monumental edifices, chiefly *heroa* and sanctuaries. Along the banks of the Eurotas stretched the *Dromos* (Racecourse), in which were several *gymnasia*, with temples of the Dioscuri, of the Graces, &c., and numerous statues; and still further south lay a broader level, Platanistas, so called from the plane trees that grew there. This was the scene of those mock-contests in which the Spartan youth learned to face without fear the realities of war.

The history of S. is really the history of Laconia. *When* the four hamlets, the *Pre-Dorian* S., originated, we have no knowledge; but it cannot be doubted that their inhabitants were Achæans. It is during the rule of the Achæan princes that the events of the famous, but unhistorical, expedition against Troy, forming the subject of Homer's *Iliad*, are described as taking place. Menelaus, husband of Helen, whose flight with Paris, occasioned the Trojan war, was king at S., and it was during the reign of his grandson, Tisamenus (according to the legend), that the Dorians (q. v.) invaded Peloponnesus.

The *fact* of a Dorian invasion is universally admitted, but of the details, scanty even as they are, we may safely be sceptical. We cannot even be certain of the date of the event, or even of the century in which it occurred. All that is clear is, that the native Achæan population were deprived of political privileges, and appear henceforth as *Perioeci* (q. v.) and Helots (q. v.)—the Dorian conquerors alone forming the historical Spartans. Towards the middle of the 8th c. B.C., the Dorians of S. had not only thoroughly established themselves in their new settlement, but had subjugated the whole of the fertile and beautiful vale of Lacedæmon, commonly known as Laconia, and had begun to cherish ambitious views of extending their supremacy over the other Dorian settlements in Peloponnesus—viz., those of Messenia and Argos. Hence originated the Messenian wars (see MESSENIA), which terminated (668 B.C.) in the complete overthrow of the Dorians of Messenia, who were reduced by the victorious Spartans to the condition of Perioeci. Similar struggles occurred both with the older Archæan inhabitants in the center of Peloponnesus and with the Dorians of Argos, &c., in which the Spartans were generally successful. The development of their warlike and ambitious character is usually ascribed to the institutions of Lycurgus (q. v.); and whatever we may think of that more than semi-mythical personage, the institutions that go under his name were well fitted to make the Spartans exactly what they figure in history—a race of stern, cruel, resolute, rude, and narrow-minded warriors, capable of a momentary self-sacrificing patriotism (as in the story of the 300 heroes who fell at Thermopylæ), but utterly destitute of the capacity for adopting or appreciating a permanently noble and wise policy.

The outbreak of the Peloponnesian war (431 B.C.) brought the rivalry between S. and Athens to a head, and in the mighty struggle that ensued, victory declared on the side of the combatant least capable of maintaining the greatness of Greece. S. now attained the hegemony of Greece; but her insolent tyranny in the hour of her triumph excited the indignation of those whom she held in virtual subjugation, and the glorious retaliations of the Thebans under Epaminondas (q. v.) stripped her of all her splendid acquisitions, and reduced the Laconian state to its primitive boundaries. Later, the rise of the Macedonian power limited still more the Spartan territory, nor did it ever after attain its earlier dimensions. Finally, after a series of vicissitudes, S. passed into the hands of the Romans, became a portion of the Roman province of Achaia, and shared the fortunes of the great republic.

SPA'RTACUS, the leader in the great insurrection of Roman slaves in Southern Italy which took place 73 B.C., and in all probability the first servile captain in point of genius of whom history preserves a record, was a native of Thrace, and originally followed the occupation of a shepherd, but afterwards became a robber-chief. Having the misfortune to be taken prisoner, he was placed in a training-school for gladiators kept by one Lentulus Batiatus, at Capua. A conspiracy to escape was formed among the gladiators (200 in all, and mostly Gauls and Thracians), the heads of which were S., and two Gauls, Crixus and Œnomaus. The conspiracy was discovered; but 70, among whom were the leaders, forced their way through the streets of Capua with cleavers and other such rude weapons as they could seize, defeated a detachment of Roman soldiers sent to bring them back, and established themselves on Mount Vesuvius, where they received considerable accessions to their number—chiefly runaway slaves. Three thousand Roman troops under C. Claudius Pulcher sought to blockade them here and starve them into surrender. S. was now chosen as their leader, with Crixus and Œnomaus for his lieutenants. Descending the hill at a place and in a way totally unexpected, he took his assailants in the rear, and inflicted on them a disgraceful defeat. His original design had been limited to securing his freedom, and making his way back to his own country, nor during the two years that the insurrection lasted did he ever forget this ultimate aim; but in order effectually to carry it out he recognized the necessity of a far more serious and extensive warfare than had yet been waged, and proclaiming freedoom to all slaves, he contrived to raise his trivial mutiny to the dignity of a servile war. Circumstances were favorable.

A great portion of Italy, especially of Central and Southern Italy, had been turned into pasture-land (see ROME), and instead of villages of sturdy and independent farmers, who owned the land they tilled, gangs of discontented slaves watched the flocks and herds of great nobles, demoralized by a plethora of ill-gotten riches. It was to these slaves that S. appealed, and his summons was not in vain. Thousands upon thousands rushed to his standard, and victory followed him wherever he went. The story of his triumphs reads like a romance. No knight of chivalry was ever more uniformly successful, for a time. After defeating Claudius Pulcher, he routed and slew Cossinius, legate of Publius Varinus; then he worsted Varinus himself in several engagements, capturing his lictors and the very horse on which he rode. All the southern part of the peninsula now fell into his hands: the country was devastated, the cities either pillaged or garrisoned. But S. knew too well the enormous resources of Rome, and the extraordinary energy which she was capable of exhibiting in the hour of peril, to hope for final success, and he consequently sought to induce his victorious bands to march northwards to the Alps, and disperse to their own homes, the Gauls to the west, and the Thracians to the east. But the slaves were too deeply intoxicated with their success to see the wisdom of his proposal, and S. had to continue his career of mere fighting against his better judgment, and embarrassed by the jealousies that are so apt to spring up among undisciplined and servile hordes. What brilliant gallantry and skill he showed, is known to all readers of Roman history. After the defeat and death of his lieutenants, who had separated from him (72 B.C), he marched north through Picenum towards the Po, overthrew first one consular army under Cn. Cornelius Lentulus and then another under Gellius Poplicola, and at the head of 100,000 men, meditated a march on Rome.

Since the days of Hannibal, there had never been such danger! Fortunately, servile indecision and unwisdom saved the city. S. was forced by his followers to retreat south, and took up his winter-quarters at Thurii, where he held a great fair for the sale of the spoils of Roman cities. In 71 B.C. Crassus (q. v.) took the field against the terrible slave-leader, but for a while even he could do nothing. Near Mutina, the proconsul C. Cassius Longinus, and the proprætor, Cn. Manlius, were defeated; in Picenum Mummius, a legate of Crassus's was utterly routed; at last, however, Crassus succeeded in forcing S. into the narrow peninsula of Rhegium, whence he tried to get into Sicily, with a view of rekindling the servile war that had recently raged in that island, but failed in his attempt, through the treachery of those with

whom he had opened negotiations. Crassus now built lines of circumvallation to hem him in, and force him to surrender; but one stormy winter-night, S. broke out of the toils prepared for him, and resumed the offensive, although he had suffered heavily by loss and desertion, and his forces were still further diminished by the formation of an independent army of Gallic slaves, which had no sooner got a leader of its own, than it was annihilated. Near Petelia, he once more defeated his adversaries; but seeing clearly that with such wretched materials as he had he could not hold out much longer, he made a dash at Brundusium, hoping to seize the shipping in the harbors, and get safely across the Adriatic to his native shore, but was baffled by the presence of Lucullus (q. v.). Pompey, too, had returned from Spain. There was nothing left for S. but to die as gallantly as he had lived. Drawing up his army in battle-array, and solemnly slaying his war-horse, he began his last fight in a spirit of heroic desperation and after performing prodigies of valor, fell unrecognized among the heaps of his slain foes. After his death, the slave insurrection was at an end.

SPASM (Gr. *spasma*) consists in an irregular and violent contraction of muscular parts—involuntary even when the voluntary muscles are concerned. There are two sorts of spasms. In one, there is an unusually prolonged and strong muscular contraction, not rapidly alternating as usual with relaxation, the relaxation only taking place slowly, and after some time. This is known as *tonic spasm* (Gr. *tonos*, a bracing up) or *Cramp* (q. v.). 'When in a more moderate degree affecting the voluntary muscles generally, it constitutes Catalepsy (q. v.), in which, from the muscles remaining contracted, the limbs will retain whatsoever attitude they are placed in, until the spasm is over. But the extreme example is Tetanus (q. v.), in which the spasms are so violent and so enduring, that they may be said to squeeze the patient to death.'—Williams's *Principles of Medicine*, 2d ed. p. 72. In the other form of spasm, the contractions of the affected muscles take place repeatedly, forcibly, and in quick succession; the relaxations being, of course, equally sudden and frequent. This is named *clonic spasm* (Gr. *klonos*, an agitation), and is popularly known as *convulsions*. Chorea (or *St. Vitus's dance*), epilepsy, and convulsive hysteria, afford examples of this kind of spasm.

The treatment varies according to the cause of the excessive muscular irritability. Firm pressure on muscles affected with spasm will promote their relaxation, and by strong steady pressure on the masseter muscles, the lower jaw has been depressed, so as to open the mouth, in cases of lock-jaw. The medicines which are employed to counteract irregular or inordinate muscular action are termed *antispasmodics;* but spasm may depend upon so many different causes that the remedies which are found most successful in combating it must vary extremely in their nature. There are, however, a few medicines which appear to exercise a control over spasmodic action generally. These may be termed *pure* or *true* antispasmodics. They are Asafœtida, Cotyledon umbilicus (or Common Navel-wort), Wood-soot, Galbanum, Musk, Rue, Sagapenum, Sumbul (Jatamansi or Musk Root), and Valerian. Amongst the narcotics often useful in these affections, we may especially mention Belladonna, Cannabis Indica (or Indian hemp), Opium, and Stramonium, Sulphuric ether in draught or inhaled, and inhaled chloroform, are often of service. In some cases, remedies which directly depress the vital powers, such as the prolonged use of the warm bath, or even, in rare cases, the abstraction of blood, are the most effectual means of subduing spasm.

SPATHE (*Spatha*), in Botany, a sheathing bract which encloses one or more flowers, as in the *Narcissus*. Very frequently the flowers within a spathe are arranged upon a *spadix*, which is a succulent spike, with numerous flowers, and of which a familiar example may be seen in *Arum maculatum*. The spadix is a characteristic feature of the Palms, and in them is compound or branching, and in general is not only provided with a common spathe, but with secondary spathes at its divisions.

SPA'VIN, a disease of horses, occurs under two different forms, both interfering with soundness. In young, weakly, overworked subjects, the hock-joint is sometimes distended with dark-colored thickened synovia or joint-oil. This is bog or blood spavin. Wet bandages, occasional friction, a laxative diet, and rest, should for several weeks be diligently tried; and if such remedies prove unsuccessful, the swelling must be dressed with strong blistering ointment, or fired. The second variety of spavin is more common and serious. Towards the inside of the hock, at the head of the shank-bone, or between some of the small bones of the hock, a bony enlargement may be seen and felt. This is bone spavin. At first, there is tenderness, heat, swelling, and considerable lameness; but as the inflammation in the bone and its investing membrane abates, the lameness is less perceptible, although the animal continues to drag his leg and go stiffly. In recent and slight cases, cold water should be applied continuously; but in serious cases, when the limb is swollen and tender, hot fomentations are best. For several days, they must be perseveringly employed. When the limb is again cool and free from pain, an iodide of mercury or fly-blister should be applied, and the animal treated to three months' rest in a small paddock, the end of a barn, or a roomy loose box. In persistent cases, firing or setoning usually gives much relief.

SPEAKER, the name given to the presiding officer in either House of Parliament. In the House of Lords, the Lord Chancellor, or Lord Keeper of the Great Seal, is *ex officio* Speaker and one or more deputy-speakers are appointed by commission to take his place in his absence. Since 1851, it has been the practice to appoint but one deputy-speaker, who is the chairman of the Lords' committee, and should he also be absent, the House can choose a Speaker *pro tempore*. The Speaker of the Lords may speak or vote on any question, and has no more authority than any other member of the House.

In the House of Commons, the Speaker is a member elected to that office at the desire of the crown, and confirmed by the royal approbation given in the House of Lords. A similar office seems to have existed as early as the reign of Henry III., when Peter de Montfort signed and sealed an answer of the parliament to Pope Alexander, *vice totius communitatis;* but the title Speaker was first given to Sir T. Hungerford in the reign of Edward III. The Speaker of the House of Commons presides over the deliberations of the House, and enforces the rules for preserving order: he puts the question, and declares the determination of the House. As the representative of the House, he communicates its resolutions to others, and conveys its thanks or its censures. He is thus the mouthpiece of the House, whence his title seems to be derived. He issues warrants in execution of the orders of the House for the commitment of offenders, for the issue of writs, the attendance of witnesses, the bringing up prisoners in custody, &c. The mace is borne before him by the serjeant-at-arms when he enters or leaves the House; when he is in the chair, it is left on the table, and it accompanies him on all state occasions. He cannot speak or vote on any question, but on an equality of voices he has a casting vote. Both by ancient custom and legislative declaration, he is entitled to take precedence of all commoners.

Down to the year 1853, no provision existed for supplying the place of the Speaker of the House of Commons when he was unavoidably absent, but in that year the House, with consent of the crown, resolved that in his absence the Chairman of the Committee of Ways and Means should take the chair, and as deputy-speaker he was in 1855 invested, both by resolution of the House and by act of parliament, with the same authority *pro tempore* as the Speaker.

SPEAKING. See READING.

SPEAKING-TRUMPET, an instrument for giving concentration rather than dispersion to the waves of sound originated by the articulation of the human voice, and thereby enabling the sound to be conveyed to a greater distance. It is of the utmost use on shipboard in enabling the officers to convey orders during windy weather from one part of the deck to another, or to the rigging. The invention is ascribed to Sir Samuel Moreland, in 1670, though Athanasius Kircher laid claim to it. Moreland's trumpet was of the same form as that now in use—viz., a truncated cone, with an outward curve or lip at the opening.

The theory of the action of this instrument has never been thoroughly explained; but it is supposed that the sides of the tube throw the sound back and back in various reflections, until ultimately the waves quit the instrument in parallel lines. It does not seem to depend on vibration of the instrument.

SPEAR, a pointed weapon with a shaft of greater or less length for thrusting, throwing, or receiving an assault. See JAVELIN, LANCE, PIKE.

The *spear foot* of a horse is his far foot behind.

SPEA'RMINT. See MINT.

SPE'CIAL CASE is the name given in the law of England to a statement of facts submitted to a court for its opinion as to the proper application of the law, or proper legal inference to be drawn from such facts. It is drawn up by mutual agreement of the parties, and may be agreed upon at any stage of the suit, or even before any step has been taken in it.

SPECIAL JURY is a jury consisting of a superior class of men, such as esquires or persons of higher degree, bankers, or merchants selected by the sheriff, and formed into a separate list. Either party to an action may demand a special jury, but he must pay the extra expense, provided the judge do not certify at the conclusion of the trial that it was a proper case to be tried by a special jury, in which case the costs are part of the costs in the cause. Each special juryman gets a guinea for his attendance on the case. The advantage of a special jury is, that the jurors are less likely to be carried away with vulgar prejudices, and more intelligent, and able to understand difficult cases.

SPECIAL LICENCE, in the marriage law of England, means a licence obtained from the archbishop, which enables the priest

to marry the parties without the publication of bans, and also at any time or place other than those necessary in ordinary cases. The statute of 25 Henry VIII. c. 21, entitled an Act concerning Peter Pence and Dispensations, continued to the archbishop of Canterbury the same right as the Pope previously had to grant special licences to marry at any convenient time and place. By a regulation of Archbishop Secker in 1759, the privilege is restricted to children of peers, and privy councillors, judges, baronets, and knights. The same conditions apply to applicants as in other cases, except that the special licence merely authorizes a different time and place for the marriage than in other cases. The stamp-duty is £5.

SPE'CIALTY DEBT, in English Law, was a debt constituted by deed under seal, as a bond, which in the event of the debtor's death had a right of prior payment over Simple Contract (q. v.) debts. Such preference is, since 1870, abolished, except where a lien or other security is held for the debt.

SPE'CIES, in Natural History, a term employed to designate groups inferior to genera (see GENUS), but superior to varieties (see VARIETY). In Mineralogy, the term is of very arbitrary application, serving only, like class, order, genus, &c., the purpose of classification, although it thus indicates common characters or points of real agreement among minerals. In organic nature, it has usually been regarded as possessing a higher and more definite signification. But no term is more difficult to define. Many definitions have been proposed, but none wholly satisfactory; every attempt at definition involving more or less the adoption of some disputed theory. If, for example, a species is regarded as including all the beings which have descended from parents created with the essential characters now belonging to the species, not only is the original creation in that particular form taken for granted, but likewise the impossibility of changes in nature, which some of the most eminent naturalists regard as actually taking place, and the belief of which implies no doubt of the act of creation itself, but only a certain opinion as to some of the laws by which organic nature is governed. To regard species as mere indeterminate and fluctuating groups, capable of indefinite modification in the lapse of ages, is equally to adopt a theory. If a species is defined as containing all the individuals which are capable of intermingling without consequent sterility of progeny, other difficult questions must be decided before the definition can be adopted as to any classes of creatures, whilst to many kinds it seems incapable of application, and much that is merely theoretical is involved in it.

Naturalists have very generally regarded species as unchanging throughout the longest succession of generations, except within narrow and marked limits, and have substantially adopted the definition of Buffon: 'A *species* is a constant succession of individuals similar to and capable of reproducing each other.' Thus De Candolle, the eminent botanist, says: 'We unite under the designation of a *species* all those individuals that mutually bear to each other so close a resemblance as to allow of our supposing that they may have proceeded originally from a single being or a single pair.' And Cuvier, the great zoologist, describes a species as 'a succession of individuals which reproduces and perpetuates itself.' Here it may be remarked, that even if the permanence of species implied in these definitions were fully ascertained, and their original creation in their present form admitted as unquestionable, it would by no means follow that we must suppose every species to have proceeded from a single individual or a single pair. Nor, accepting the biblical statement concerning the human race, that all mankind are the offspring of a single pair, are we entitled to infer that such has been the case also as to all animals and plants capable of freely intermingling, and which, therefore, are commonly regarded as forming one species.

But the separate creation and immutability of species are disputed, some naturalists maintaining that species undergo modification, and that existing forms of life have descended by true generation from pre-existing forms. Lamarck was the first to proclaim this doctrine, at least so as to attract much attention, about the beginning of the 19th century. He held that all species, even including man, are descended from species of inferior organization; whilst to account for the existence of very simple forms at the present day, he had recourse to the supposition of their spontaneous generation. He was followed, with greater caution, by Geoffroy Saint-Hilaire, who regarded what we call species as various degenerations of the same type, but did not believe that the existing species are now undergoing modification. Similar views have since been stated by many authors. But the works which have most strongly directed attention to them, and in which they have been most fully advocated, are the *Vestiges of the Natural History of Creation*, by an anonymous author, originally published in 1844, and which has since passed through many editions; and Darwin's work *On the Origin of Species by means of Natural Selection*, originally published in 1859. Of the other supporters of these views, the most eminent is Professor Huxley, who, without fully adopting the views either of the author of the *Vestiges* or of Darwin, advocates 'the hypothesis which supposes the species living at any time to be the result of the gradual modification of pre-existing species,' and maintains that to suppose each species of plant and animal to have been formed and placed on the surface of the globe at long intervals by a distinct act of creative power, is an assumption 'as unsupported by tradition or revelation as it is opposed to the general analogy of nature.'

It is impossible for us to do more than very briefly exhibit the principal arguments which have been urged on this question. Lamarck rested much on the well-known effect of use or exercise in strengthening and enlarging an organ, and of disuse in atrophying it. 'He conceived that, an animal being brought into new circumstances, and called upon to accommodate itself to these, the exertions which it consequently made to that effect caused the rise of new parts; on the contrary, when new circumstances left certain existing parts unused, these parts gradually ceased to exist. Something analogous was, he thought, produced in vegetables, by changes in their nutrition, in their absorption and transpiration, and in the quantity of caloric, light, air, and moisture which they received. This principle, with time, he deemed sufficient for the advance from the monad to the mammal.' The author of the *Vestiges*, from whom this account of Lamarck's views is taken, regards him as in error 'in giving this adaptive principle too much to do;' and says: 'In the present day, we have superior light from geology and physiology, and hence comes the suggestion of a process analogous to ordinary gestation for advancing organic life through its grades, in the course of a long but definite space of time, with only a recourse to external conditions as a means of producing exterior characters.' The author of the *Vestiges* designates the principle for which he contends that of *Progressive Development*, and states it as follows: 'The proposition determined on, after much consideration, is that the several series of animated beings, from the simplest and oldest up to the highest and most recent, are, under the providence of God, the results, *first*, of an impulse which has been imparted to the forms of life, advancing them in definite times, by generation, through grades of organization terminating in the highest dicotyledons and vertebrata, these grades being few in number, and generally marked by intervals of organic character which we find to be a practical difficulty in ascertaining affinities; *second*, of another impulse connected with the vital forces, tending, in the course of generations, to modify organic structures in accordance with external circumstances, as food, the nature of the habitat, and the meteoric agencies, these being the "adaptations" of the natural theologian.'

He further regards the *nucleated vesicle* as 'the fundamental form of all organization, the meeting-point between the inorganic and the organic,' and as the starting-point of the fœtal progress of every higher individual in creation, both animal and vegetable.' Founding on instances of the production of the *proximate principles* of which organic substances are composed in the laboratory of the chemist, he goes on to say that 'an operation which would produce in these the nucleated vesicle is all that is wanting effectually to bridge over the space between the inorganic and the organic;' and that 'it does not seem, after all, a very immoderate hypothesis, that a *chemico-electric operation, by which germinal vesicles were produced*, was the first phenomenon in organic creation, and that the second was *an advance of these through a succession of higher grades, and a variety of modifications*, in accordance with laws of the same absolute nature as those by which the Almighty rules the physical department of nature.' He regards the idea of species or specific distinction, therefore, 'as *merely applicable to certain appearances presented, perhaps transiently, to our notice*.' He adduces instances of great changes of form and character known to take place in the lower departments of nature, both animal and vegetable, as giving probability to the supposition, that in a long succession of generations, great changes may take place also in the higher.

The whole theory of the author of the *Vestiges* as to organic nature has been exposed to objection in consequence of its connection with views of the general system of the universe altogether foreign to the present subject; and because of an evident inclination to the belief in a transition from inorganic to organic existence by chemico-electric operation. The argument is also weakened by the too ready acceptance of unsubstantiated facts, as of the transmutation of one kind of grain into another; and by resting too much on what may be reckoned the mere mistakes of naturalists, as to the forms of the lower kinds of plants and animals, of which genera and even tribes have been constituted, that have afterwards been found to be mere modifications or larval stages of creatures very different in their most apparent characters. Much hostility has been also excited by the extension of the theory of development to the human species, connecting man with pre-existing and inferior forms of animal existence. All this has been avoided by Darwin, by whom, however, the chief arguments of the *Vestiges* are used with great scientific caution.

Darwin's views are distinguished by the introduction of what he designates the principle of *Natural Selection*. He maintains the variability of species, and adduces much evidence to show that variation is continually taking place, in consequence of the external conditions to which plants and animals are subjected. He rests much on the difficulty of distinguishing between varieties and species, and on the changes which are known to result from cultivation and domestication. He dwells on the *selection* which man makes, in order to produce new breeds or varieties, and supposes a similar 'selection' to take place in nature, in the *struggle for life*, which all plants and animals must undergo. This *struggle for life* is, in fact, the foundation of his theory. He shows that every kind of plant or animal must maintain it, and in order to its continued existence, must be successful in maintaining it, not only against those other creatures which seem to make it their food, but still more in a competition with those which seek the same nutriment with itself. In this struggle, the stronger, or those which possess anything peculiarly favorable in their organization, must overcome the weaker, and these must therefore cease to exist. Thus a slight variation, such as often takes place, may be perpetuated; and the possessors of any advantage in the means of procuring food, or in the powers of offence or defence, may entirely displace their less favored congeners. The modifications thus taking place, Darwin regards as accounting for the changes in organized beings from one geologic period to another, and for the great differences in the plants and animals of different parts of the world.

In support of his views, he argues from the tendency to variation seen in cultivated plants and domestic animals, and the perpetuation of the forms so produced in breeds and races; and from the fact, that the variations in cultivated and domestic species are in some cases greater than those which are regarded as affording grounds of specific, and sometimes even of generic or greater distinctions in a state of nature. 'Can it be thought improbable,' he says, 'seeing that variations useful to man have undoubtedly occurred, that other variations useful in some way to each being in the great and complex battle of life, should sometimes occur in the course of thousands of generations? If such do occur, can we doubt—remembering that many more individuals are born than can possibly survive—that individuals having any advantage, however slight, over others, would have the best chance of surviving and of procreating their kind? On the other hand, we may feel sure that any variation in the least degree injurious would be rigidly destroyed. This preservation of favorable variations and the rejection of unfavorable variations, I call *Natural Selection*. Variations neither useful nor injurious would not be affected by natural selection, and would be left a fluctuating element, as perhaps we see in the species called polymorphic.' He further supports these views by pointing out the favorable opportunity for the operation of natural selection afforded in a country undergoing great physical changes, as of climate; and particularly in an island, or a country surrounded by barriers sufficient to prevent the ready immigration of species. 'In such cases,' he says, 'every slight modification, which in the course of ages chanced to arise, and which in any way favored the individuals of any of the species, by better adapting them to their altered conditions, would tend to be preserved; and natural selection would thus have free scope for the work of improvement.'

Mr. Darwin supposes new variations to be continually taking place, but the greater number of these speedily to become extinct; whilst others, becoming perpetuated, and perhaps causing the extinction of the original forms, again give rise to other forms, until some of them have so widely diverged, that all traces of their common origin are lost. He does not, however, commit himself to the opinion, that all forms of organic life, or even all plants or all animals, have a common origin. He completely rejects Lamarck's notion, that new and simple forms are continually being produced by spontaneous generation. 'I need hardly say,' he remarks, 'that science in her present state does not countenance the belief that living creatures are now ever produced from inorganic matter,' and he accounts for the existence of low forms of life by saying that 'natural selection includes no necessary and universal law of advancement or development; it only takes advantage of such variations as arise and are beneficial to each creature under its complex relations of life.' So that even the lowest forms might 'be left by natural selection unimproved, or but little improved,' as geology tells us of infusoria and rhizopods, which have remained for an enormous period in nearly their present state.

That species differ not only in single characters, but in many, Mr. Darwin accounts for by reference to unknown laws of the correlation of organs—laws, however, which, although unknown, we know to exist, so that a modification of one organ is attended with modification of other organs, as is exemplified in our domestic breeds.

In further support of the theory of natural selection, the fact is insisted upon, 'that it is the common, the widely diffused, and widely ranging species, belonging to the larger genera within each class, which vary most.' That the several subordinate groups in any class of creatures 'cannot be ranked in a single file, but seem rather to be clustered round points, and these round other points, and so on in almost endless cycles,' Mr. Darwin thinks incapable of explanation, except on the supposition of community of origin and natural selection. He points also to the analogous manner in which species of the same genus vary, as corroborative of his views. He accounts for the absence or rarity of transitional varieties by supposing the predominant forms to have taken possession of their districts, whilst these were in process of being stocked; and that these districts, differing much in their natural characters, the forms originating in the comparatively unextensive intermediate tracts, have not been able to contend against them, and have become extinct. He points out the possibility that areas now continuous may not have been so during a long period, and that species may have been formed whilst they were broken up into islands. But this remains a chief difficulty of his theory.

He ascribes to natural selection the results which Lamarck ascribed to use and disuse in the development and atrophy of organs; and thinks it not impossible that the flying squirrels may thus have had a common origin with the true squirrels, and the *Galeopithecus* with the lemurs, although he admits that we have no graduated links of structure connecting them together. 'Nor can I see any insuperable difficulty,' he says, 'in further believing that the membrane-connected fingers and forearm of the *Galeopithecus* might be greatly lengthened by natural selection; and this, as far as the organs of flight are concerned, would convert it into a bat.' Like Lamarck and the author of the *Vestiges*, Mr. Darwin rests not a little on the unity of type throughout whole classes of creatures, and the homologies of parts very different from each other, as in the four-limbed structure of the vertebrata generally, and even the articulations of the limbs. He endeavors to trace the eye from its simplest to its most perfect form, and shows how gradual are the transitions found on comparison of existing creatures, from the one to the other. He goes even further, and says: 'Several facts make me suspect that nerves sensitive to touch may be rendered sensitive to light, and likewise to those coarser vibrations of the air which produce sound.'

He dwells at great length on the subject of hybridism, and the general sterility of hybrids, endeavoring to show that it presents no insuperable objection to the theory of a gradual modification of species, their sterility being incidental on other differences, and sterility occurring, as he labors to prove, when varieties are crossed, as well as in the hybrids of distinct species. The difficulties presented by geology he obviates very much by insisting on the imperfection of the geological record. He does not adopt the view of the author of the *Vestiges*, that the geological record exhibits to us a succession of animals corresponding in their progressive development with the fœtal development of the mammalian embryo. But he founds an argument on the many connecting links in the general system of nature which fossils supply when compared with existing species. And he endeavors to show that his theory is perfectly consistent with the known facts of the geographical distribution of species, and in particular with the remarkable facts of the peculiarity of the fauna and flora of some of the lonely oceanic islands, and of the frequent occurrence of the same species both in cold regions comparatively near the pole, and on mountains far remote from each other in lower latitudes; referring the latter class of facts to former geologic periods, when the continental areas were not the same as now, or when the prevailing climatic conditions were very different. And he finds support for his views in the correspondence, without identity, of the floras and faunas of the northern parts of America and of the Old World.

It is but a very imperfect sketch which we have thus been able to give of Darwin's theory, and of the arguments by which it is supported. Whatever may be thought of the truth of the theory, it must be admitted to be admirably framed and guarded, and to be maintained not only with great ingenuity of argument, but by the aid of a vast store of scientific information, most skilfully used. Its opponents condemn it as resting upon unwarrantable assumptions, and demand some proof, for example, of the transition of organs from a simple or rudimentary to a complex and more perfect state. They also refuse to acknowledge such imperfection of the geological record as Darwin's argument demands, and they insist much on the completeness of the changes which that record discloses, and the absence of transitional forms both among fossils and existing species. Much of what Darwin and other advocates of the same general views contend for, they admit; a certain power of development in organic nature, a 'struggle for life,' and 'natural selection;' but they regard the limits of development and variation as comparatively narrow. Nor would the state of the question, as they believe, be materially affected, if many of what have hitherto generally been regarded as species,

should be proved to be mere varieties. Any number of such errors of naturalists might be exposed and corrected, without modification of our views of the laws of nature; and errors of this kind are precisely such as might be expected, when the forms of organic life began to be discovered and described, and ere yet there was time for their mature study in all parts of the world, and under all various circumstances.

The doctrine of Darwin is usually spoken of as the *Evolution Theory*. But it must be remembered that it is not the only possible theory of evolution; Darwin's fundamental idea being that of evolution by *Natural Selection*—'survival of the fittest,' as Herbert Spencer expresses it. Darwinism has made the most remarkable progress during recent years. Scarcely a living naturalist now entirely rejects it, and the vast majority indeed are earnestly occupied in its elucidation and application. The theory too is being extensively applied in sociology and philosophy. It should here be mentioned that the theory of Natural Selection was arrived at independently by Mr. A. R. Wallace (q. v.). See articles on DARWIN, DARWINIAN THEORY, ZOOLOGY, MAMMALIA, &c.; as also Darwin's *Origin of Species*, *Descent of Man*, and other works; Lyell's *Principles of Geology;* Huxley's *American Addresses* and *Science and Culture;* Haeckel's *Natural History of Creation;* Meunier's *Le Darwinisme*, &c.

SPECI'FIC GRAVITY of any body is the proportion which the weight of a certain bulk of that body bears to the same bulk of another body, which is taken as a standard. The standard for substances solid and liquid is distilled water at the temperature of 62° Fah., barometer 30 inches; and the weight of a cubic inch of this standard is given in the Parliamentary Reports for 1825 as 252·456 troy grains, hence a cubic foot of it weighs 997·129 avoirdupois ounces, or 62·82 avoirdupois pounds. It is convenient to remember that a cubic foot of water weighs about 1000 ounces avoirdupois, as the error resulting from employing this estimate does not amount to much more than $\frac{1}{160}$th of the whole. For aëriform bodies, the standard is atmospheric air, a cubic inch of which, at a temperature of 32° Fah., weighs ·32698, and at 60° Fah., ·30935 grains troy.

The specific gravity of solid bodies is best measured by the hydrostatic balance—a figure of which is given under ARCHIMEDES, PRINCIPLE OF (q. v.)—which gives the weight of a volume of water equal in bulk to the solid, by which it is only necessary to divide the weight of the solid in air to obtain the specific gravity; that of liquids may be obtained by the Areometer (q. v.), or by comparing the weight lost by a solid body in the liquid and in water, and dividing the former by the latter—or by means of the *specific-gravity bottle*, which holds exactly 1000 grains of distilled water in its standard condition. The bottle is emptied of water, filled with the liquid, and then weighed; the result gives the weight of a volume of the fluid equal in bulk to 1000 grains of the standard, and hence this weight divided by 1000 gives the specific gravity. The specific gravity of an aëriform fluid is determined by weighing a glass globe filled first with the fluid, and then with atmospheric air. Annexed is a table of the specific gravity of a few of the more common substances.

SPECIFIC LEGACY. See LEGACY.

SPECIFIC PERFORMANCE, in English Law, is the compulsory execution or carrying out of a contract in its details, the Court of Chancery generally having alone jurisdiction to enforce specific performance. In Scotland, the corresponding phrase is Implement. As a general rule, the courts do not attempt to enforce specific performance, but as a substitute, give the party injured by the breach of contract satisfaction in the shape of damages.

SPE'CTACLES, for the purpose of aiding the sight when impaired by age or otherwise (see SIGHT, DEFECTS OF), were invented during the 13th century. The merit is attributed by some to Alexander di Spina, a Florentine monk, and by others to Roger Bacon. At first, they were exceedingly clumsy, both in the lenses themselves and also in their frames; and but little improvement took place in them until the beginning of this century, when light metal frames were introduced, instead of the cumbrous horn or tortoise-shell mountings, which are still occasionally seen, and have obtained the name of goggles. So skilful are the workmen of Wolverhampton, where they are chiefly made, in the manufacture of steel frames, that some of exquisite workmanship are now turned out, which, with their lenses complete, are under a quarter of an ounce in weight. They have consequently displaced gold, silver, and all other materials, when comfort and effectiveness are preferred to useless show combined with inconvenience. The lenses themselves are nearly always made of the best optical glass, and by the best makers are ground with extreme care. Many profess to be made of 'pebbles,' or rock-crystal; but lenses really made of that material are exceedingly rare, and have no real advantage over good glass.

SPECTRE BAT (*Phyllostoma*), a genus of bats having two membranous crests on the nose, the one leaf-like, the other in the form of a horseshoe. This gives to their face that peculiar appearance from which they derive their popular as well as their scientific name. The species are numerous, and all natives of the West Indies and South America.

SPECTROSCOPE, the instrument by the aid of which spectral phenomena (see SPECTRUM) may be most conveniently studied. It consists essentially of, first, an illuminated slit, from which parallel rays of light proceed; secondly, a prism or train of prisms, to separate the differently refrangible rays; and thirdly, a telescope, to view a magnified image of the specturm produced. See SUN.

SPE'CTRUM (Gr.) is a term applied in Optics to the colored image of the sun or other luminous body, produced by Refraction through a Prism (q. v.), by Diffraction (q.v.) through a fine grating, &c. In what follows we shall confine ourselves to the spectrum produced by a prism, as that which is commonly used. Besides, so far as we have at present occasion to examine it, it presents very nearly the same appearances as spectra produced by other processes.

The solar spectrum was first carefully examined by Newton, who deduced from his observations the composite nature of white light, and the different refrangibilities of its various colored constituents. A ray of sunlight enters a darkened room through a

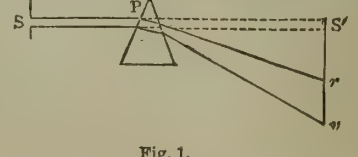

Fig. 1.

small hole, S, in a shutter. It proceeds in a straight line to the opposite wall, and forms at S′, as a circular white spot, an image

of the sun. If the edge of a glass prism, P, be interposed in the path of this ray, the white spot at S′ disappears, and the spectrum, *r*, *v*, is produced. In this form of experiment, its shape is that of a rectangle with semicircular ends, as figured below.

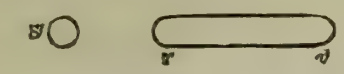

Fig. 2.

The breadth of the spectrum is equal to the diameter of the spot S′; and it is brilliantly colored, the end *r*, nearest to S′, being red, and the other end, *v*, violet. Between these we have gradations of color, and the whole appeared to Newton to be divisible into seven differently colored spaces, which he called red, orange, yellow, green, blue, indigo, violet. This was in accordance with the speculations of old days, when analogies were constantly looked for, and seems to have been suggested to Newton by the common musical scale. It is impossible, however, to settle precisely the exact boundary between any two of these fancied species of color; and, besides, such a description of the spectrum (though complete enough for mere popular language) is totally inadequate to express our present knowledge of the subject. In order to study the spectrum a little more closely, suppose we have pieces of colored glass which allow only one definite color to pass. With a red glass placed at the hole in the shutter, the prism being removed, the effect would be to render the spot S′ red, without changing its position. Introduce the prism, and the effect is to change the position of the spot to *r*, without altering its size or color.

Fig. 3.

Similarly, with a violet glass we have a violet spot at *v*, and so on; the change of position, due to refraction, being least for red and greatest for violet. It thus appears that the spectrum formed in this way, is made up of a series of circular spots, of the various colors of which white light consists, all of the same size, and having their centers ranged along a line, so that each overlaps those next it. The only parts of the spectrum which are *pure*, i. e., where no two or more colors are mixed, are the ends; so that, by this process, it is impossible to separate definitely the rays of different refrangibility, so as to see, for instance, *whether any are wanting*. How, then, are we to ascertain whether sunlight contains rays of every refrangibility from red to violet? The obvious method is to make the spot S′ not circular, but long and very narrow, a process mentioned by Newton himself. In such a case our figure would become

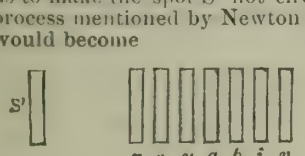

Fig. 4.

and, by making S′ narrow enough, we shall evidently be able to avoid overlapping of the various colored images, *unless there be present, in white light, rays of every refrangibility from red to violet.* To make this spot S′ thus narrow, a method commonly employed, is to set the prism about half-way between the shutter and the screen, and to place before it a lens, such that, if the prism were removed, S′ would be an image of the hole in the shutter nearly equal to it in size. The hole must, therefore, be a narrow slit, parallel to the edge of the prism. When this arrangement is adjusted we have a pure spectrum, and we find it to be (at first sight) *continuous*. Thus, it appears that sunlight contains rays of every refrangibility, from the highest to the lowest; and that Newton's sevenfold division of it, though sometimes convenient for popular reference, has no scientific basis. Besides, what we can see is not the whole spectrum but a mere fraction of it; for beyond the red end, there are invisible rays recognized at once by their heating powers; and beyond the violet there are invisible rays more powerful than the visible in producing chemical changes, as on a photographic plate, and which can be changed into visible rays by fluorescent substances. See PHOSPHORESCENCE. The breadth of the visible spectrum evidently depends on the *length* of the slit, its length on the difference of refrangibility of red and violet.

If we cut a narrow slit in the screen on which the spectrum falls, in a direction perpendicular to its length, the light which passes through has a definite refrangibility, and can no longer be drawn out by a prism into a spectrum. This experiment also is due to Newton.

If the slit in the shutter be very narrow, and the prism be adjusted to the most favorable position (so that the incident and refracted rays make equal angles with the surfaces on which they impinge, and from which they escape, respectively), we see that, after all, the solar spectrum is *not* continuous. It is found to be crossed at intervals by dark bands, (a few of which are sketched below, fig. 5), showing the absence of rays of certain definite refrangibilities. The phenomenon is found to be the same whatever be the substance of the prism; so that these rays are really wanting in sunlight.

This important discovery was made by Wollaston, but the bands were first carefully observed and measured by Fraunhofer, from whom they are commonly called *Fraunhofer's Lines*. We owe to Fraunhofer the invaluable suggestion of employing a telescope to examine the spectrum. The refracted rays are received directly on the object-glass of the telescope, which forms an image of the spectrum to be examined with the aid of the eye-piece, the screen being dispensed with. Wollaston had seen only five lines; Fraunhofer at once discovered four hundred; Brewster, with more perfect apparatus, counted two thousand; and now, with a train of prisms, and powerful telescopes, their number seems beyond computation. They show every variety of breadth and distinctness, and are grouped in the most irregular manner. For reference, Fraunhofer selected some of the more prominent, to which he attached the earlier letters of the alphabet. By their help he was enabled to measure refractive indices (see REFRACTION) with a precision completely unlooked for. If the light of a candle, a bright gas-flame, a white-hot wire, or a lime-ball in the oxhydrogen flame, be examined in the same way, *no such lines are seen.* But some of them, and others not apparently belonging to sunlight, were found by Fraunhofer in the spectra of various fixed stars—while the light of the moon and planets seemed to give spectra similar to that of sunlight.

The first to throw any light on this subject was Brewster. He showed that when light passed through nitrous acid gas its spectrum was interrupted by countless lines; and that they increased in number and breadth by the application of heat to the gas, so that at a high temperature a thin layer of this gas is *opaque to direct sunlight*. Hence it was natural to conclude that the dark bands in the solar spectrum are caused by absorption in some medium lying between us and the sun. It is to be observed, however, that this is on the supposition that light as it comes immediately from the sun would give, like that of the lime-ball, a continuous spectrum. But Brewster went farther. He showed that *some* of Fraunhofer's lines depend on the altitude of the sun, that is on the greater or less space of air, fog, and vapor through which his rays must pass before reaching the earth. *Some of them*, then, *are caused by absorption in the earth's atmosphere.*

But we must now look to another class of phenomena. A spirit-lamp flame gives a very feeble spectrum; and, if a little common salt be put on the wick, although the flame becomes instantly very much brighter, no alteration is produced on the spectrum save the appearance of a *bright* yellow line crossing it at the place where the dark line, called by Fraunhofer, D, appears in sunlight. On examining this line carefully, Fraunhofer found that it, like D, is double—and he verified that these two rays were exactly (so far as refractive index goes) two of those wanting in sunlight, and in the light of some of the stars.

About the same time Talbot and Herschel (q. v.) showed that the colors given by Lithia, Strontia, &c., in a spirit-flame were, like that produced by common salt, due to the production of light of several perfectly definite refrangibilities: so that the spectrum of the lamp-flame was crossed in each case by a series of bright lines, always the same when the same body was placed in the flame; and they suggested (in 1825) the application of this method to the qualitative analysis of minerals, &c., when the presence of extremely minute quantities of different bodies has to be ascertained. This was, in reality, the foundation of SPECTRUM-ANALYSIS; and the method was, we may say, almost complete so far as practice is concerned. The theory, however, was left incomplete so far as regards the cause of dark lines in the solar spectrum. Foucault (in 1849) seems to have been the first to approach the true explanation. An experiment of his, from which, however, he drew no inferences, contains the complete theory. When salt is placed in the voltaic arc (ELECTRIC LICHT, q. v.) the spectrum gives the double bright line (coinciding with the double dark line D) already referred to. When sunlight passes through this arc its dark line D is *strengthened*, instead of being filled up, by the yellow light from the arc as we might have expected; and when one of the white-hot carbon-points (which gives a continuous spectrum) is looked at through the yellow arc, the double dark line D appears in its spectrum.

Stokes learning, in 1850, that experiments had been made by Professor Miller of Cambridge, to test with great accuracy Fraunhofer's assertion as to the exact coincidence of the double bright line of a salted flame with the double dark line of the solar spectrum, gave for the first time the physical explanation of the phe-

nomenon. He compared the salt-flame to a space full of tuning-forks or piano-forte wires all tuned to the same note. When they are in vibration they, of course, give out this note—similarly the salt-flame the *bright* lines. When, however, sounds are produced in their neighborhood, as they naturally vibrate to one definite note, they will be set in vibration by it (i. e., will absorb it) if it be part of the sound.—Thus sound which has passed through such a space has had this note eliminated from it—similarly the salt-flame seizes these yellow rays from white light passing through it. This ingenious and satisfactory explanation shows at once that the line D proves the existence of salt (or sodium) in the atmosphere of the sun. Stokes's theory was not published, except in so far as it was annually given by Sir W. Thomson (q. v.) in his lectures in Glasgow—so that it was independently discovered, or all but discovered, by various other philosophers some 8 or 10 years later. The earliest of these was Balfour Stewart of the Kew Observatory, who proved by reasoning and experiment that a body's absorbing power for any ray of light or heat is equal to its radiating power for the same. Angström all but made the rediscovery. Finally, Kirchhoff, by reasoning similar to that of Stewart, and by actually reversing the spectra of certain substances, arrived at the same results; and, in conjunction with Bunsen, applied them to chemical analysis, with the immediate result of discovering two new metals.

One of the most valuable parts of Kirchhoff's investigation, is his map of the solar spectrum with its dark lines; side by side with which is a spectrum containing the bright lines given by various metals volatilized in an electric spark. The sunlight is admitted through the upper half of the slit, the light from the burning metal through the lower—and thus the two are subject to precisely the same deflections by the train of prisms. The following figure shows a very small portion of Kirchhoff's drawing, and exhibits the exact coincidence of the bright lines produced by highly heated vapors of iron, magnesium, nickel, and calcium, with corresponding dark lines in the solar spectrum. The particular portion exhibited (in the middle of the green), is chosen because it contains few lines

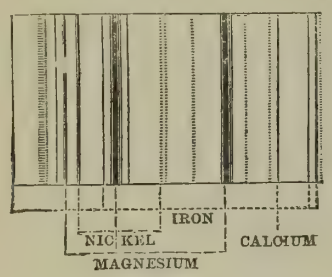

Fig. 5.

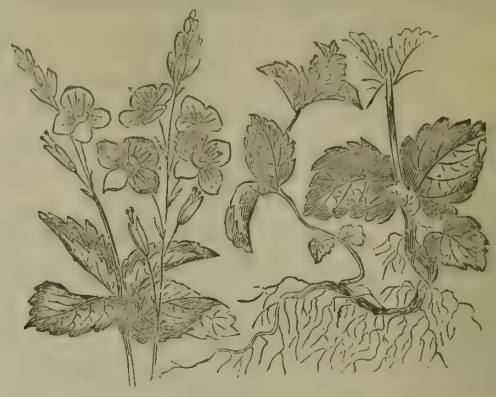
whose origin has not been ascertained. But *every* bright line in the iron spectrum has a corresponding dark line in the solar spectrum. Kirchhoff has calculated from his data the probability that the sun's atmosphere contains iron; and finds it to differ from certainty by a quantity almost inconceivably small.

The applications of the spectrum-analysis are becoming more numerous every day. We have space only for two of the most beautiful and important. Huggins has lately shown that the spectra of planetary nebulæ, and of the tails of comets, consist of a few *bright* lines only—indicating that these bodies—or, at all events, those portions of them from which their light proceeds—are masses of incandescent vapors or gases.

Again, Stokes has traced, by the alteration of the absorption bands produced by the coloring matter of blood, the oxidation and reduction which constantly take place in this substance, and its connection with the distinction between venous and arterial blood.

SPE'CULUM METAL, an alloy of copper and tin, used for making the reflecting surfaces of reflecting telescopes. The best consists of 126·4 parts copper to 58·9 tin. To obtain a perfect alloy, and to cast it successfully, is a matter of great difficulty, requiring much skill and experience. See TELESCOPE.

SPEE'DWELL (*Veronica*), a genus of plants of the natural order *Scrophulariaceæ*, distinguished by a 4-cleft wheel-shaped corolla, with the lower segment narrower, two stamens, and a two-celled capsule. The species are very numerous, annual and perennial herbaceous plants and small shrubs, natives of temperate and cold climates in all parts of the globe. Some of them grow in wet ditches and in marshes, some only on the driest soils. They have generally very beautiful blue, white, or pink flowers. The number of British species is considerable, and few wild-flowers are more beautiful than the Germander S. (*V. Chamædrys*), or the alpine species, *V. alpina* and *V. saxatilis*. A number of species are very generally cultivated in flower-gardens.—The bitter and astringent leaves of the COMMON S. (*V. officinalis*), one of the most abundant British species, found also in almost all the northern parts of the world, are in some countries used as a tonic, sudorific, diuretic, and expectorant medicine. They are also em-



Germander Speedwell (*V. Chamædrys*).

ployed, particularly in Sweden, as a substitute for tea; as are those of the Germander S.—*V. Virginica* is called *Calver's Physic* in N. America; it is said to be actively diuretic, and a decoction of the fresh root is violently cathartic and emetic.—Brooklime (q. v.) belongs to this genus.

SPEISS, a residue found in the bottoms of crucibles in which smalts or cobalt glass has been melted. It consists of nickel, arsenic, sulphur, with traces of cobalt, copper, and antimony.

SPEKE, JOHN HANNING, an African traveler, was born near Bideford, Devonshire, in May 1827, was educated at the Barnstaple grammar-school, and at the age of 17 went to India. He entered the native Bengal infantry as a cadet, and saw much service during the war in the Punjab. A keen sportsman, with a taste for natural history, he employed his rifle with success in collecting for the museums specimens of the rarer mammals and birds of India, and with this view he undertook several exploratory trips into the Himalaya. It was while so employed that he first conceived the idea of becoming an African traveler. The English government had resolved, in 1854, to despatch an expedition from Aden into the neighboring region of Africa, under the command of Captain Burton (q. v.). S., then a lieutenant in the Indian army, reached Aden at this time, on leave of absence and resolved to join Burton and his companions, Lieutenants Herne and Stroyan. Burton went to Harar; and S. was detached to visit the Dalbahantas, the most warlike of the Somauli tribes. On the return of the travelers to their starting-point on the coast, they were attacked by 150 men. Stroyan was killed, and S. made a narrow escape with 11 wounds. The attention of the Geographical Society of London had now been called to the subject of the great lakes of tropical Africa; and in June 1857, they despatched Burton and Speke. These travelers entered the country from Zanguebar, as the German missionaries Krapf and Rebmann had done in 1847, and discovered the great lake Tanganyika. In returning to the coast Speke marched alone to the northwards, and discovered the Victoria N'Yanza. In 1860 he returned to Africa, accompanied by Captain Grant, to confirm his former discovery, when he explored the western and northern shores of N'Yanza, and discovered an outlet to the northwards. See the article NILE. On their return to England in 1863, they met with an enthusiastic reception. The substantial correctness of the geographical discoveries of S. has been established by H. M. Stanley, who sailed round the Victoria N'Yanza in 1876. On the 15th September 1864, S. was killed by a gun-accident while out shooting in the neighborhood of Bath, to which he had come to be present at a meeting of the British Association.—S. is the author of a *Journal of the Discovery of the Source of the Nile*, and *What led to the Discovery of the Source of the Nile*.

SPELTER. See ZINC.

SPENCER, HERBERT, who has attempted to work out a complete system of philosophy in harmony with the principles and results of modern science, was born at Derby in 1820. His father was a schoolmaster in that town, and, about 1814, became honorary secretary of the Derby Philosophical Association, a society which had been founded by Dr. Erasmus Darwin. From his father, S. imbibed that love of natural science and wonderful faculty of observation so conspicuous in his works. The father seems to have been chiefly interested in entomology; and S. himself used to collect, describe, and draw insects when a boy. Rejecting the Cambridge career recommended by his uncle, the Rev. Thomas Spencer—a clergyman well known for his liberal opinions on social and political questions—he became a civil engineer at Derby

at the age of 17; but about eight years afterwards, gave up this profession, having gradually entered on journalistic and literary work. He had already contributed various papers to the *Civil Engineers' and Architects' Journal;* and in the latter half of 1842, he wrote a series of letters to the *Nonconformist* newspaper on 'The Proper Sphere of Government,' which were republished in pamphlet form in 1843. These letters imply a belief in human progress based on the modifiability of human nature through adaptation to its social surroundings, and maintain the tendency of these social arrangements 'of themselves to assume a condition of *stable* equilibrium.' From 1848 to 1853, he was engaged on the *Economist* newspaper; and at this time he developed the ethical and political consequences of the ideas he had already enunciated, and sought an independent basis for them in his first important work, *Social Statics* (1850). It is thus noticeable that S.'s philosophical activity began with ethical and social questions.

The evolution of man and society as determined by circumstances, and the idea that organic and social evolutions are under the same law, *preceded* the elaboration of those scientific ideas which, in the complete *System of Philosophy*, are made to serve as their basis. The truth anticipated by Harvey and Wolff, but first put into definite shape by Von Baer—'the truth that all organic development is a change from a state of Homogeneity to a state of heterogeneity'—is regarded by S. as the organizing principle of his subsequent beliefs. It was gradually developed and applied by him in a series of articles contributed in the following years to the *Leader*, the *North British*, *Medico-Chirurgical*, *Westminster*, and other reviews.

In these essays, especially those on *Manners and Fashion* (1854), and *Progress: its Law and Cause* (1857); and in the volume of *Principles of Psychology* (1855), the doctrine of evolution began to take definite form, and to be applied to various departments of inquiry. The publication of Darwin's *Origin of Species*, in 1859, gave a wide basis of scientific proof for what had hitherto been matter of speculation, and first showed the important part played by natural selection in development.

In 1864, S. published an essay on the *Classification of the Sciences*, in which he criticised Comte's serial arrangement of the sciences according to generality, and substituted for it a classification according to abstractness: (1) *Abstract Science*, treating of the forms (space and time) in which phenomena are known to us—logic and mathematics; (2) *Abstract Concrete Science*, treating of the laws of the factors of the phenomena themselves—mechanics, physics, chemistry, &c.; (3) *Concrete Science*, treating of the phenomena in their totalities (the laws of the products)—astronomy, geology, biology, psychology, sociology, &c.

Upon this scheme of the sciences, S. had now been working for several years. As early as 1860 he had announced the issue of a *System of Synthetic Philosophy*, already in course of preparation, which, beginning with the first principles of all knowledge, proposed to trace how the law of evolution was gradually realized in life, mind, society, and morality. In pursuance of this comprehensive design, S. has published *First Principles* (1861); *Principles of Biology*, 2 vols. (1864–67); *Principles of Psychology*, 2d edition, 2 vols. (1870–72); *Principles of Sociology*, vol. i. (1876); 'Ceremonial Institutions' (1879), and 'Political Institutions' (1882), composing vol. ii.; 'Data of Ethics,' being Part 1. of *Principles of Morality* (1879).

In method, S.'s philosophy is essentially speculative or deductive. It does not begin with observation and experiment, and rise through them to scientific generalizations. Its starting-point is certain truths supposed to be ultimate, and the source from which all others are to be deduced; and its justification is sought in its ability to explain phenomena from its assumed standpoint. This is not merely due to the adoption of the synthetic form of exposition. The ultimate test is in all cases the mental inconceivability of the opposite of the proposition by the individual thinker.

Metaphysically, S.'s system is founded on the doctrine of relativity Hamilton and Mansel deduced from Kant, but carried, as he says, a step further. Along with the definite consciousness of things known in relation to one another, there is implied an indefinite consciousness of an absolute existence, in the recognition of which as inscrutable, science and religion find their reconciliation. All definite consciousness or knowledge is of the manifestations of this unknowable power; and knowledge, completely unified, is philosophy.

The data of philosophy are necessarily those organized components of our intelligence without which philosophizing could not go on. 'Our postulates are: an unknowable power; the existence of knowable likenesses and differences among the manifestations of that power; and a resulting segregation of the manifestations into those of subject and object.' Within each segregated mass there are likenesses and differences involving secondary segregations. The modes of cohesion under which manifestations are invariably presented are called, when contemplated apart, space and time; when contemplated along with their manifestations, matter and motion. All these are traceable to experiences of that mode of consciousness whose reality is shown by its persistence—to force. By the 'persistence of force' is meant the unchanging quantity both of that mode of force which is revealed to us only by opposition to our own powers, and is not a worker of change, and of that mode which is a worker of change actual or potential, and is specifically termed energy. The persistence of force—that is, the persistence of some cause which transcends our knowledge and conception—is the truth which all other truths imply, and from which they all (including the law of evolution) are derived. From the fact that force can neither arise out of nor lapse into nothing, follows the uniformity of law. Force never disappears; it is only transformed. Motion follows the line of least resistance, and is perpetually reversed within limits—is rhythmical. So far of the factors of phenomena. The phenomena themselves must be under a law of the concomitant redistribution of matter and motion, which holds of every change. The law of the entire cycle of changes passed through by every existence is loss of motion and consequent integration, i. e., evolution, eventually followed by gain of motion and consequent disintegration, i. e., dissolution. In its complete shape, the 'formula of evolution' is thus stated: 'Evolution is an integration of matter and concomitant dissipation of motion; during which the matter passes from an indefinite incoherent homogeneity to a definite coherent hetrogeneity; and during which the retained motion undergoes a parallel transformation.' This law of evolution applies equally to all orders of phenomena—whether 'astronomic, geologic, biologic, psychologic, sociologic, &c.'—since these are all component parts of one cosmos, though distinguished from one another by conventional groupings.

So long as evolution is merely established by induction, it does not belong to philosophy. It must be deduced from the persistence of force. And this can be done. For any finite aggregate being unequally exposed to surrounding forces will become more diverse in structure; every differentiated part will become the parent of further differences; at the same time, dissimilar units in the aggregate tend to separate, and those which are similar, to cluster together ('segregation'); and this subdivision and dissipation of forces, so long as there are any forces unbalanced by opposite forces, must end at last in rest; the penultimate stage of this process, 'in which the extremest multiformity and most complex moving equilibrium are established,' being the highest conceivable state.

The various derivative laws of phenomenal changes being thus deducible from the persistence of force, it remains to apply them to inorganic, organic, and superorganic existences. The detailed treatment of inorganic evolution being omitted from S.'s plan, he proceeds 'to interpret the phenomena of life, mind, and society, in terms of matter, motion, and force.'

It is impossible to give here any but the most general idea of the contents of the volumes in which the law of evolution is applied to these different departments. It is not only made to account for the phenomena within each group, but also for the connection between one science and another. The researches of Darwin had accumulated ample material for showing the continuity of development, structural and functional, in plants and animals; and S.'s view of biology, and the definition of life he proposes ('the definite combination of heterogeneous changes both simultaneous and successive in correspondence with external co-existences and sequences'), are meant to show its connection both with inorganic changes on the one hand, and with mind on the other.

Now, just as biology has to deal with the connection between phenomena in the organism, and as physical science treats of the connection between phenomena in the environment, so psychology has to do with the connection between these two connections. For this is said to be the objective aspect of what states of consciousness are subjectively. The functions dealt with by the psychologist are more special than those dealt with by the biologist; but they belong to psychology, not merely because they are more special, but also because they are the counterparts of the states of consciousness dealt with by the science of subjective psychology.

Objectively, an attempt is made to trace the evolution of mind from reflex action through instinct to reason, memory, feeling, and will, by the inter-action of the nervous system with its environment. Subjectively, mental states are analyzed, and it is contended that all of them—including those primary scientific ideas, the perceptions of matter, motion, space, and time, assumed in the *First Principles*—can be analyzed into a primitive element of consciousness, something which can only be defined as analogous to a nervous shock. These perceptions have now become innate in the individual. They may be called—as Kant called space and time—forms of intuition; but they have been acquired empirically by the race through the persistence of the corresponding phenomena in the environment, and from the accumulated experiences of each individual being transmitted in the form of modified structure to his descendants.

This principle of heredity is one of the laws by which individuals are connected with one another into an organic whole; and we thus pass quite naturally to what S. calls super-organic evolution, implying the co-ordinated actions of many individuals, and giving rise to the science of sociology. Society, like an individual man, is shown to be an organism from the fact and laws of its growth, the nature of its activities, and the inter-dependence of its parts; though it is distinguished from the individual organism in this, that it is discrete, while the latter is concrete: 'there is no social sensorium.' As societies progress in size and structure, they work on one another profound metamorphoses, now by war-struggles and now by industrial intercourse.

Assisted by a series of elaborate ethnographical charts (*Descriptive Sociology*) prepared under his direction, S. has attempted to trace the development of human ideas, customs, ceremonial usages, and political institutions. The genesis of religion is traced to ancestor-worship, or generally to worship of the dead. The notion of another life—from which those of gods and God are gradually evolved—is originated mainly by 'such phenomena as shadows, reflections, and echoes'—these being looked upon as indications of a 'double' or other self, which is not extinguished with the death of the first self. It is this fear of the dead which is the root of the religious control, just as it is the fear of the living, which is the root of the political control. Ceremonies and institutions alike have their root in this fear of the stronger and submission to the conqueror. Thus, early communities being of the predatory or militant type, tended to centralized control; while industrial communities, which are now gaining ground, tend to free institutions and to the restriction of the sphere of government to the negative duty of preventing interference (*laissez faire*). A still higher type than the industrial is possible in the future, by inverting the belief that life is for work, into the belief that work is for life; just as the industrial inverts the belief that individuals exist for the state, into the belief that the state exists for individuals.

The principles of morality are looked on by S. as the copestone of his system, all his other investigations being only preliminary to them. Ethics, he holds, has its root in physical, biological, psychological, and social phenomena, for by them the conditions of human activity are prescribed and supplied. The best conduct is that which most fully realizes evolution—which promotes the greatest totality of life in self, offspring, and fellow-men—the balance of egoism and altruism being attained by a compromise between these contending principles. The measure of life is said to be pleasure, but the Utilitarian school are at fault in assuming that the end (greatest happiness) is better known than the means to it (morality); and for ignoring the fact, that accumulated experiences of utility have become consolidated in the race into a moral sense.

In the above summary, it has been impossible to give any idea of either the strength or weakness of the proof by which this elaborate system is supported. In general, it may be said that its strength lies in the author's brilliant power of generalization, his acquaintance with various departments of science, and his unsurpassed wealth of illustration. But a clear analysis of the notions he employs is often wanting. Hence, the unsatisfactoriness of the distinction between definite consciousness or knowledge, and the indefinite consciousness implied by it, which is not knowledge; the want of any proved relation between his objective and subjective aspects of psychology; the implicit assumption at the outset of the perceptions of space, &c., when the attempt is being made to show how they have been gradually produced in the mind, by the action of the environment. Thus, too, in the *Sociology*, the ethnographical method is followed to the exclusion of the more scientific historical method; and in the *Data of Ethics*, the compromise between egoism and altruism is left wholly indeterminate. Besides the works already mentioned, S. is the author of a volume on *The Study of Sociology* (1872), and of a book on *Education* (1861). His occasional papers have been collected and published in four volumes of *Essays: Scientific, Political, and Speculative.*

The wide knowledge which all his writings display of physical science, and his constant endeavor to illustrate and support his system, by connecting its positions with scientific facts and laws, have given his philosophy great currency among men of science—more so, indeed, than among philosophical experts. At the same time, not only have the development and application he has given to the theory of evolution, profoundly influenced contemporary speculation, but he must also be regarded as one of the few in history who have carried out the attempt to give a systematic account of the universe in its totality. S. has founded a school of thought in America; and to it is due one of the best philosophical treatises adopting his principles—the *Outlines of Cosmic Philosophy*, by John Fiske.

SPENCER, JOHN CHARLES, EARL, English minister and statesman, son of the second earl, was born in 1782. The founder of the family of the Spencers was the Hon. John Spencer, youngest son of the third Earl of Sunderland by Anne, daughter and co-heiress of the great Duke of Marlborough, and who inherited much property from his grandmother, Sarah, Duchess of Marlborough. His only son was made Earl Spencer in 1765.—The second earl was First Lord of the Admiralty under Mr. Pitt's administration—1794 to 1801—the period of the great naval victories of Camperdown, Cape St. Vincent, and the Nile. He retired when Mr. Addington became premier, and became distinguished as a munificent collector of rare books. He was also first President of the Roxburghe Club for reprinting rare and curious tracts.—The third earl, the subject of this notice—better known under the courtesy title of Lord Althorp—was educated at Harrow School, and afterwards at Trinity College, Cambridge. He entered parliament in 1804 as member for Oakhampton. In 1806, his father took office as Secretary of State for the Home Department in the Grenville-Fox ministry, and S. became a junior Lord of the Treasury. He was returned for Northamptonshire, which he represented from 1806 until the period of the Reform Bill. In the Reformed parliament he sat for the southern division of the county. He went out with the Whigs in 1807, and during the long interval of their exclusion from office, steadily opposed the measures of the Tory government.

On the dissolution of the Wellington cabinet in November 1830, he was appointed Chancellor of the Exchequer and leader of the House of Commons in the celebrated Reform ministry of Earl Grey. The Reform Bill was introduced by Lord J. Russel (q. v.), but the task of carrying the bill mainly devolved upon Spencer. In 1833, he brought in and carried the ministerial Bill for reforming the Irish Church. In this memorable working session, the curious statistician discovered that S., who had, from his post of ministerial leader, naturally been the most frequent speaker, had addressed the House 1026 times, his speeches occupying 387 columns in the then *Mirror of Parliament*. In 1834, he introduced and obtained the assent of the legislature to the Poor-law Amendment Act. When the Irish Coercion Bill was under consideration in the cabinet, S. had opposed the clauses prohibiting public meetings, yet had given way rather than break up the ministry; but when the truth was elicited in debate by Mr. O'Connell, S. resigned. He was considered and described by Earl Grey as his 'right-hand man,' and without his assistance the earl felt himself unable to carry on the government. The administration of Viscount Melbourne succeeded (July 1834), in which S. consented to resume his office. In November he was called by the death of his father to the House of Peers, which had the effect of bringing the Melbourne (q. v.) administration to an end. When the attempt of Sir R. Peel to carry on the government failed, S. declined to take office again. He devoted his time to agricultural pursuits, became President of the Smithfield Cattle Club, and suggested the formation of the Royal Agricultural Society, of which he was elected President in 1838. He died at his seat, Wiseton Hall, Notts, October 1, 1845, without issue, and was succeeded by his brother. During his political career, his simplicity of character and integrity of purpose obtained for him the appellation of 'honest Lord Althorp.' He was very little of an orator, but he had a clear and practical intellect, and his influence over the Reformed House of Commons was supreme. Lord Brougham dedicated to him his work on *Natural Theology;* and his *Dialogues on Instinct* are also supposed to be carried on with S., to whose cultivation of philosophy in the midst of his political and agricultural pursuits, the author bears friendly testimony. See *Memoir* by Sir Denis Le Marchant, Bart. (London, 1876).

SPENCER GULF, a very large inlet on the coast of S. Australia (q. v.), between Eyria Peninsula on the W., and Yorke Peninsula on the E. It is about 209 m. in length, by 100 m. in greatest breadth.

SPENER, PHIL. JAK., an illustrious German reformer, and the founder of the sect known as *Pietists*, was born at Rappoltsweiler (Fr. Ribeauville) in Upper Alsace, January 25, 1635. His father was legal adviser to the Count von Rappoltsweiler. At an early age, S. showed deep religious susceptibilities. After studying the classics, at Colmar, he betook himself in 1651 to Strasburg, where the professors Dannhauer and Seb. Schmidt inspired him with a profound love of the Scriptures, not as a heap of dry theological bones, but as a fountain of life and spiritual thought. From 1659 to 1662, he attended the universities of Basel, Tübingen, Freiburg, Geneva, and Lyon. In the following year, he became a preacher at Strasburg, where the unction of his sermons exercised a powerful influence on his hearers. At the age of 31, he was transferred to Frankfürt as first pastor; and here, as elsewhere, the profound spiritualism of the man, springing out of a free simple *un*theological faith in the Bible, made itself apparent in his preaching and life. Yet S. was the very opposite of what is commonly called a *mystic*. The devotion which he sought to excite were not to show themselves in transcendental ecstacies, amid which common sense is apt to swoon away, but in acts of piety, humility,

and charity. The 'Sermon on the Mount' was the medium through which he gazed upon the 'truth as it is in Jesus.' He had a strong aversion to what goes by the name of theology, which he considered a hateful caricature of the free word of life; and he commenced in the year 1670, at his house, meetings for the cultivation of evangelical morality. These were the famous *collegia pietatis*, whose influence for good on the German character, in those days of stony and barren orthodoxy, cannot easily be overvalued. At the same time he took pains to reorganize the method of catechising, and to improve the religious instruction given to children.

His conduct in all this was marked by such prudence and discernment, that he long escaped the animadversions of the 'high and dry' Lutherans; but in 1679, a preface which he wrote for a new edition of the *Postille* of Arndt, in which he censured the morals of the upper classes, made him the target for their envenomed shafts; and after some years, he was fain to accept the invitation to become court-preacher at Dresden, and member of the Upper Consistory. In this capacity, he effected important ameliorations in the theological teaching of the university of Leipsic, and in the system of religious catechising practised throughout Saxony; but in 1689 he fell into disgrace for having addressed a temperate but energetic remonstrance to the elector Johann Georg III., on the subject of his personal vices, was attacked by Carpzow, who coveted his place at court, and by other orthodox theologians, and in 1691 went to Berlin as Provost of the Church of St. Nicholas, and consistorial inspector, offices which he retained to the end of his life. The Elector of Brandenburg encouraged his efforts after religious reform, and intrusted theological instruction in the new university of Halle to Franke, Breithaupt, and other disciples of S.—a matter that excited great irritation in the theological faculties of Wittenberg and Leipsic, which had formally censured as heretical no less than 264 propositions drawn from S.'s writings. S. died at Berlin, February 5, 1705, leaving behind him a reputation for piety, wisdom, and practical Christian energy, which all the excesses of the later pietists have not obscured. His writings are numerous; the chief are *Pia Desideria* (Frankf. 1675), *Das geistliche Priesterthum* (Frankf. 1677), *Christliche Leichenpredigten* (13 vols., Frankf. 1677), *Des thätigen Christenthums Nothwendigkeit* (Frankf. 1679), *Klagen über das verdorbene Christenthum* (Frankf. 1684), *Evangelische Glaubenslehre* (Frankf. 1688), and *Theologische Bedenken* (Halle. 5 vols., 1700—1721). See Hossbach's *Phil. Jak. S. und seiner Zeit* (2 vols., Berl. 1828); Thilo's *S. als Katechet* (Stutt. 1841); and Wildenhalm's *Phil. Jak. S.* (Leip. 1842—1847).

SPENSER, EDMUND, one of the chief literary ornaments of the great Elizabethan period, was born in London in the year 1553. There is some ground for supposing him to have been of good family connection; but inasmuch as of neither of his parents is any thing whatever known, the evidence of this is precarious. In 1569, he went to Pembroke Hall, Cambridge, in the humble capacity of sizar, in itself a sufficient proof that whatever his family, the gifts of fortune were deficient. At Cambridge, he remained several years, becoming Bachelor of Arts in 1572, and Master in 1576. After leaving college, he went to live with friends in the north of England. Of the detail of his life at this period, nothing is known further than that he busied himself with poetry, his first volume of which, *The Shephearde's Calendar*, was published in 1579. Its dedication to Sir Philip Sidney was the means of introducing him to that noble and kindly gentleman, who not only extended to him a generous patronage, but honored him with his warm friendship. He seems for some time to have been domesticated with Sir Philip at Leicester House, from which he dates his moiety of the *Foure Epistles*, exchanged between him and Gabriel Harvey, and printed in 1580. Towards the end of this year, through the influence of Sidney's uncle, the Earl of Leicester, an appointment was procured for him as secretary to Lord Grey of Wilton, the queen's deputy in Ireland, whither he at once proceeded. About this time it was that he commenced his great work, *The Faery Queen*. His official duties must have been punctually and ably performed, as in 1586 we find his services rewarded by a grant from the crown of Kilcolman in the county of Cork, an estate of upwards of 3000 acres, on which he now went to reside. Along with this piece of good fortune, came the evil news to him of the death of his friend Sidney at Zutphen, an event which he musically bewails in the elegy entitled *Astrophel*. Subsequently, the place of Sidney, as at once his patron and friend, was in a measure supplied by Sir Walter Raleigh, who visited him in Ireland in 1590, took him along with him to England, and introduced him to the notice of Queen Elizabeth.

His experiences as a suitor for court-favor seem not to have been specially of a pleasant kind, if we may judge from a passage in one of his works, in which a keen personal feeling of wrong and weary humiliation speaks out unmistakably. Documentary evidence exists, however, that a pension of £50 per annum was granted him by Queen Elizabeth; that it was ever paid, or paid with due punctuality, there seems considerable reason to doubt. That Elizabeth, along with her greater qualities, could exhibit on occasion an extreme meanness and stinginess, there is no reason to doubt whatever. What portion of S.'s after-life was passed in England, what in Ireland, we do not distinctly know. Nearly all we distinctly know of him henceforth is the date of his several publications. The first three books of *The Faery Queen*, issued on his arrival in England in 1590, were followed the year after by three more, and a collection of lesser pieces entitled *Complaints*, including *Mother Hubbard's Tale*, the *Tears of the Muses*, &c.; and in 1596, by four *Hymns*, so called, in which the Platonic doctrine of Beauty is elaborated in noble music. In 1596, he wrote his *View of Ireland*, a treatise full of sagacious observation and remark, which was only published long after in Dublin in 1633. Further than this, all record which survives to us of S. is summed in the facts, that in 1594 he was married to a woman whose very name has perished; that in 1598 he was made sheriff of Cork by the queen; and that in the course of the same year the deplorable calamity befell him, which shortly preceded, and, in part, may have caused his death. Tyrone's rebellion having broken out, his house at Kilcolman was sacked and burned by the rebels, he and his wife with difficulty escaping, whilst their youngest child perished in the flames. On January 15, 1599, his death took place in London. According to the account given by Ben Jonson to Drummond, he '*died for lake of bread.*' This is not likely to have been in the literal sense true, but it is scarce possible to evade the inference from it, as coming from one so likely to be well informed as Jonson, of a state of great wretchedness and destitution. He was buried by his own request near Chaucer in Westminster Abbey, at the expense of the Earl of Essex, who is said, in the account by Jonson, to have tendered him succor on his deathbed, though too late to be of any avail.

S. takes admitted rank as one of the very greatest of our poets; and his chief work, *The Faery Queen*, written in that stateliest of English measures, since known by the name of its inventor, tedious as it is in its allegory, and in much of its diction obsolete even when written, is a masterpiece of opulent genius. In the poetry of S., an ever-present seeking for and sense of beauty finds its fit expression and reflex in a fluent succession of sweet and various cadences; in breadth and splendor of pictorial effect, it has never, perhaps, been surpassed; such a lavish exuberance in detail as we find in it, has seldom been so combined with a total impression of chastened and majestic sobriety; and throughout it is pervaded by that atmosphere of moral wisdom and serenity which Milton reverently recognizes in 'the sage and serious Spenser.'—See *Spenser and his Poetry*, by Prof. G. L. Craik (3 vols. 1845). The most complete edition of the poet's works is that by Todd (Lond. 8 vols. 1806); but a new edition, with glossary, notes, and life, by Collier, was published in 1862. Church's short life of S. (1879) is admirable.

SPENSE'RIAN STA'NZA. See METRE.

SPERMACE'TI is a waxy matter obtained from a cavity in the head of the whale, *Physeter macrocephalus*. See CACHOLOT. It is separated from the oil, in which it is originally dissolved, by boiling water, from which the spermaceti crystallizes as it cools. It is then purified by being remelted in a weak solution of potash, and the impurities skimmed off, and it is finally melted again by the action of steam, and cooled slowly in moulds. Its specific gravity is 0·943; it is scarcely unctuous to the touch; does not melt under 100°, has little taste or odor, and occurs in pearly-white, glistening translucent crystals. It was generally regarded by chemists as a palmitate or cetylate of oxide of cetyl; but according to Heintz, who has studied the fats and their allies more, perhaps, than any other living chemist, it contains four alcohols (which act as bases), united with lauric, myristic, palmitic, and stearic acids.

Spermaceti is an emollient and demulcent, and is hence a useful ingredient in cough mixtures. It is, however, chiefly used externally as an ingredient in various ointments. The *Unguentum Cetacei*, or *Spermaceti Ointment*, of the Pharmacopœia consists of a mixture of spermaceti, white wax, and almond-oil.

SPERMATOZO'A is the term given to the true fertilizing agents occurring in the male generative organs. They appear to be formed from the epithelial lining of the tortuous seminal tubes, of which the organ known as the *testis* is essentially composed. At the period of puberty in man, and at certain periods annually in other animals, the seminal tubes are seen to be filled with cells, from which the spermatozoa are developed. Without describing the various changes that ensue, we may observe, that the spermatozoa are finally set free by the bursting of the cell-walls, and arrange themselves in parcels, symmetrically placed, with the so-called heads in one direction, and the tails in the opposite direction. In the human subject, the spermatozoa may be described as clear, hyaloid bodies, each of which consists of a dilated portion, the head or body, from which a long tail, or filament, issues. The head is flattened from side to side, and of a

conical form, the pointed extremity being anterior. The length of the spermatozoa is about $\frac{1}{800}$th of an inch. The spermatozoa of different animals vary extremely in size and form; and for a detailed account of these bodies, in different classes of animals, we must refer to the article 'Semen,' in the *Cyclopædia of Anatomy and Physiology*. It was formerly supposed that spermatozoa were independent organisms (like the infusoria, for example), but it is now known that they must be regarded as epithelial cells (or perhaps nuclei), modified in structure, and endowed with special properties. That the integrity of the spermatozoa is essential for the process of impregnation, is a fact that cannot be called in question; but of the nature of the force which they communicate to the ova, we know nothing.

SPEY, a river of Scotland, rises in the south of Inverness-shire, 6 miles north-west of Loch Laggan, and 10 miles east of Loch Lochy, follows a north-eastern direction through the counties of Inverness and Elgin, and, after a course of about 110 miles, falls into the Moray Firth, three miles west of Port-Gordon. During a portion of its lower course, it forms the boundary between the counties of Elgin and Banff. In point of length, the S. is the second river of Scotland; but except for its salmon-fisheries, it is almost without value, nor can it be called a picturesque stream. It has the swiftest current of all the large rivers in Britain, and is subject to sudden and violent freshets, resulting at times in disastrous inundations. Its salmon fisheries are very valuable.

SPEY'ER, also SPEIER (Fr. *Spires*), the capital of Rhenish Bavaria (the former Palatinate), and one of the oldest towns in Germany, stands at the influx of the Speyerbach into the Rhine, 14 miles south-west of Heidelberg, and 23 north of Carlsruhe. It is connected with Mannheim, and thence with the rest of Germany, by railway. The principal building is the cathedral (founded 1030), which contains the tombs of numerous emperors of Germany. Since 1856, it has been wholly renewed, and is the grandest specimen of Romanesque architecture in Europe. It has a hall of Roman antiquities discovered in the Palatinate, and is adorned with thirty magnificent frescoes by Schrandolph.

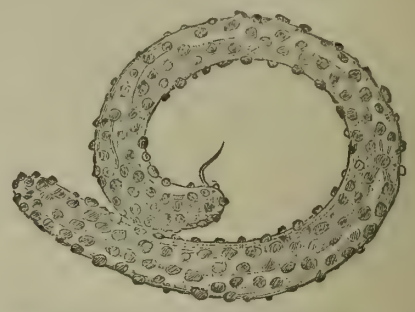
Except the cathedral and a ruined wall, the sole relic of the imperial palace in which twenty-nine diets were held—at one of which (1529) the Reformers made their famous 'protest,' and got for themselves the name of Protestants (see PROTESTANT)—S. does not contain a single ancient building. This is owing to the fact, that in the Orleans Succession War—well called by the Germans the *Mordbrenner Krieg*—during which the whole Palatinate was savagely wasted, S. was taken by the French, its inhabitants driven out, and the city blown up with gunpowder, and burned to the ground. Only the cathedral resisted the barbarous efforts to mine it. Everything else was reduced to rubbish, and for long years the noble old pile overlooked nothing but a melancholy waste of ruins. In 1794, it was wasted by the French under Custine, and has never recovered from these calamities. S. manufactures vinegar and tobacco, and has some transit-trade on the Rhine. Pop. (1880) 15,589, of whom about two-fifths are Catholics.

S. is the *Noviomagus* of the Romans, and was the capital city of the Nemetes, a German people. S. was probably the native name from the first, for in some of the later Roman notices it is called *Civitas Nemetum, id est Spira*. The name is derived from the stream, or *bach* (Speyerbach), which here flows into the Rhine. A Christian community appears to have been established here as early as 150—200 A.D., and it was certainly the seat of a bishop about 300 A.D. The German emperors had here a *pfalz* (palace, Lat. *palatium*, whence the former name of the region of which it was the capital, the Pfalz or Palatinate), in which they often resided. By them the town was made a Free City of the Empire; and having obtained the monopoly of the carrying-trade up and down the Rhine, it rapidly rose in wealth and importance. The *Reichskammergericht*, or Imperial Chamber of Justice, the highest court of the German Empire, was held here for 200 years, until removed to Wetzlar in 1689.

SPE'ZIA, a city of Northern Italy, province of Genoa, and 60 miles south-east of the city of that name. Pop. (1881) 19,864. It is situated near the inner point of the gulf of that name. The gulf is formed by the bifurcation of a spur of the Apennines, and is $3\frac{1}{2}$ miles long and 3 miles broad; its western shore is indented by many coves or creeks, five of which—Porto-Venere, La Castagna, the Varignano (the Quarantine station), Grazie, and Panigaglia—are so deep that large men-of-war may be moored in them. The Emperor Napoleon I. recognized the importance of this gulf, and at one time designed, it is said, to make it the chief naval station of his empire in the Mediterranean. The Italian government has made it the station for its ships of war, and it is now the chief arsenal of the kingdom. Its shipping and commerce is considerable. The scenery of the gulf is very beautiful, and the mildness of its climate was famous in ancient times, when it was known as the Gulf of Luna. The soil produces olives, excellent wines, fruits, &c., and the town has become within recent years a much frequented watering-place. There are numerous foreign consulates. Steamers perform the voyage from S. to Genoa in eight hours. The railway from Genoa to S. was completed in 1873.

SPE'ZZIA (the ancient *Tiparenos*), a small Greek island at the entrance to the Gulf of Nauplia. Pop. 12,000. The island is unfruitful, and its people are engaged chiefly in commercial pursuits. The town of S., on the north coast, has more than 6500 inhabitants.

SPHÆRULA'RIA, a very remarkable nematode, or round worm, which exists as a parasite in various species of bees. The female is almost an inch in length, has a nearly uniform diameter of $\frac{1}{15}$th of an inch, is of a whitish color, is bluntly pointed at each end, and is covered with numerous (about 800) small button-like projections—a peculiarity to which it owes its name. There is neither mouth, œsophagus, intestine, nor anus, and the whole animal consists of little more than an elongated mass of fatty tissue and reproductive organs, which in full-grown individuals con-



Sphærularia bombi; Male and Female:
Magnified 9 diameters. The male is seen as a thread-like appendage attached to the extremity of the female.—From Cobbold's *Entozoa*.

tain ova in various stages of development. Although the female was discovered in 1836 (by Leon Dufour), it was not until January 1861 that the discovery of the male was announced by Mr. Lubbock in his memoir on this parasite in *The Natural History Review*. The male is more than 28,000 times smaller than the female, which accounts for its having been previously overlooked. It is frequently found sexually united to the female in the same manner as occurs in *Sclerostoma syngamus* (q. v.), the parasite which gives rise to the *Gapes* in various birds.

SPHA'GNUM, a genus of Mosses, whose spore-case is an urn closed by a deciduous lid, and its brim toothless, the calyptra irregularly torn. Several species are natives of Britain, and are common in bogs, from which they derive their popular name, BOG MOSS. They are remarkable for the whitish color of their leaves. They are very elegant plants. They often grow in considerable masses, absorbing water like a sponge, but becoming friable when dry. They contribute much to the formation of peat. Gardeners employ them in preference to other mosses for covering the roots of plants and keeping them moist, as they have in a high degree the property of absorbing moisture from the atmosphere. They have been used as food in barbarous countries, but are very slightly nutritive. The cells of the leaves are remarkable for their spiral structure, and for large pores in their sides.

SPHE'GIDÆ, or SPHECIDÆ, a family of hymenopterous insects, winged in both sexes, and much resembling bees or wasps in general appearance. They are solitary in their habits. Many of them burrow in sand, and are known as *Sand wasps*. They are extremely active and restless, and may be seen running about on sandhills, with their wings in constant motion. Some of them carry spiders, and others caterpillars, into their burrows, as food for their larvæ, placing them there when the egg is laid, and stinging them so as to render them torpid, without killing them. They display wonderful energy and perseverance in dragging the spider or caterpillar to the burrow. They are mostly tropical insects, but some species are found in Britain.

SPHE'NOID BONE (Gr. *sphen*, a wedge, and *eidos*, form) is situated at the anterior part of the base of the skull, and articulated with all the other cranial bones, which it wedges firmly together. It somewhat resembles a bat with its wings extended, and hence was termed the *Os vespertilionis*. It is divisible into a body, the greater and lesser wings, and various processes. The greater wings present three surfaces: a superior or cerebral surface, forming part of the floor on which the brain rests; an anterior surface, which assists to form the outer part of the orbit of the eye; and an external surface with a rough ridge, giving attachment to the external pterygoid muscle, one of the most powerful muscles of mastication. The second, third, fourth, fifth, and

sixth cranial nerves emerge from the cranial cavity through foramina in this bone. Although considered in human anatomy as a single bone, it may be regarded as composed of several bones,

The Upper or Cerebral Surface of the Sphenoid Bone:

1, the olivary process; 2, the ethmoidal spore; 3 and 4, the lesser and greater wings on the left side; 6, the extremity of left pterygoid process; 7, the foramen for the optic nerve; 10, the sella turcica on which the petuitary gland rests; 12, the basilar portion of the bone, joining with the occipital; 13, part of the sphenoidal fissure which separates the greater from the lesser wings, and transmits the 3d, 4th, the ohpthalmic division of the 5th, and the 6th nerves, with the ophthalmic vein; 14, the foramen rotundum, transmitting the second division of the 5th nerve; 15, the foramen ovula, transmitting the third division of the 5th nerve; 16, the foramen sponosum for the passage of the middle meringeal artery.

which, after a time, unite with one another, as the basi-sphenoid, the pre-sphenoid, the ali-sphenoid, and the orbito-sphenoid bones.

SPHERE, a regular solid figure, every point of whose surface is equally distant from its center; and whose outline is traced by a circle revolving round its diameter. All sections of a sphere by a plane are necessarily circles, and all sections by planes passing through the center, or by planes cutting the sphere at equal distances from the center, are eqhal. The former sections are called *great*, and the latter *small, circles*. Small circles may vary in size between a mere point and a great circle, approaching either limit as nearly as we please. The surface of a sphere is equal to that of four of its great circles, or (taking x for the radius of the sphere) to $4\pi x^2$; and its volume to that of a cone whose altitude is twice that of the sphere, or $4x$, and whose base is a great circle of the sphere, the formula for it being $\frac{4x}{3} \times \pi x^2$, or $\frac{4}{3}\pi x^3$. The most remarkable geometrical property of the sphere is the relation which its surface and volume bear to those of the 'circumscribing' cylinder, i. e., a cylinder whose length and diameter of each end are each equal to the diameter of the sphere, and in which, therefore, the sphere will be exactly contained. The concave surface of such a cylinder is exactly equal to the surface of the sphere; and not only so, but if a section parallel to the base of the cylinder be made through both cylinder and sphere, the curved surfaces of the portions cut off are equal, whether such a portion be cut off from one end or be intercepted between two parallel sections; it follows from this that the curved surface of any section of a sphere with parallel ends is equal to the product of the circumference of a great circle of the sphere by the height or thickness of the section, and that the curved surfaces of all sections of a sphere are proportional to the thickness of such sections. The volume of the sphere, also, is equal to two-thirds of that of the circumscribing cylinder.

SPHE'ROGRAPH, a simple and exceedingly efficient instrument for the mechanical solution of such problems in spherical trigonometry as navigation, geography, &c. present, was invented in 1856 by Mr. Stephen Martin Saxby, R.N. It consists of two circular pieces of paper, the whole of the under and the rim of the upper being made of stout card-board, and the interior portion of the upper one of strong transparent tracing-paper; these two circles are attached by a pin through their common center, the pin being made to work in an ivory collar, so as to prevent any lateral motion of either circle. Round the pin as center, equal circles are drawn, one on each sheet; each circle is then filled in with lines representing meridians and parallels according to the stereographic projection, and the instrument is completed. As one of the chief uses of the spherograph is to show the course, distance, and differences of latitude and longitude in 'Great Circle Sailing' (q. v.), we shall give a problem of this sort in illustration of the working of the instrument. Fig. 1 represents the appearance presented by the spherograph when the two poles are separated from each other by an angular distance of 40°; the lines drawn on the under circle (represented by *dotted lines* in the fig.) showing through the transparent paper which forms the upper circle, on which the continuous lines are delineated.

Suppose, then, that a ship is in lat. 50° N., long. 20° W., and is bound for a point in lat. 10° N. and long. 80° W., and that its great circle track, &c., are required: let P, the pole of the under circle, represent the place of the ship (the circle ZPD always representing the meridian of the point of departure, and the upper circle, whose pole is Z, representing the earth's hemisphere), which is done by turning the upper circle till P appears at lat. 50° N.; X represents the point to be arrived at, and consequently PX, the arc of a great circle passing through P and X, is the great

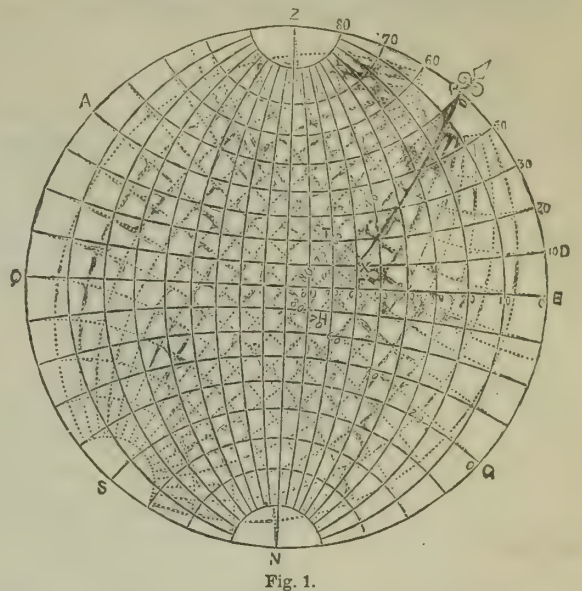


Fig. 1.

circle track, PD is the difference of latitude, EF the difference of longitude; the spherical angle XPD, measured by GH, an arc of a great circle, of which P is the pole, is the course; and the length of PX is measured by PT, the portion of PS which is cut off by a parallel of the under circle through X, in degrees. The data, then, being as above, we find by inspection of the instrument the difference of lat. = 40° S., the difference of long. = 60° W., the course = S. 72½° W., and the distance = 63½° = 3800 nautical miles. Besides the saving of time and labor by the use of this instrument—the whole work being the *setting* of the instrument, and then the reading off of the required elements—it is evident that the substitution of a mechanical solution for calculation greatly lessens the probability of error. It is found that spherographs of 5 inches radius give results of sufficient accuracy for all the purposes of the navigator.

All other spherical problems can be solved with equal facility by this instrument, but one more example will suffice. Let Z (fig. 2) now represent the zenith of a place, ZHNR its meridian,

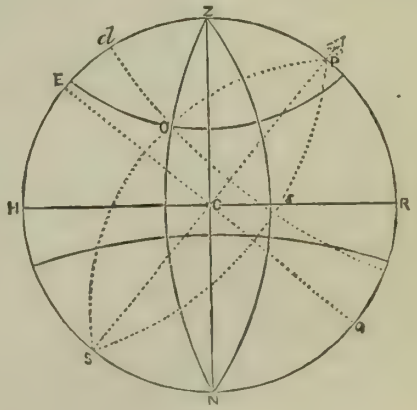

Fig. 2.

P the north pole of the heavens; the other lines are then circles of declination, altitude, azimuth, and hour circles; and let O represent the place of the sun in given declination and altitude at a certain time. The instrument is now set by turning round the upper card till the point O (determined by its circle of declination and hour circle) on the under card falls upon the circle of given altitude on the upper card; then d is the sun's place at noon, Hd being his meridian altitude, PR the latitude of the place, the angle RPS (measured in degrees along QE) the time of sunset, ds half the length of the day, sc half the length of the night, &c. The spherograph is also useful in finding latitude when the horizon is hid by fogs, right ascensions at night, and in correcting lunar observations; but for these purposes, spherographs are specially

constructed, as some slight variations in the form given above are necessary.

SPHE'ROID is a species of Ellipsoid (q. v.), and is represented by the same equation. If an ellipse be made to revolve round one of its axes, the curved outline of the ellipse describes the spheroid. Should the major or longer axis be the axis of revolution, the spheroid is said to be *prolate* (Lat. *prolatus*, lengthened), but if the minor or shorter axis, *oblate*. The earth's axis of revolution, which runs from pole to pole, being about 25 miles shorter than the longest or equatorial diameter, and these being at right angles to each other, the earth is considered as an oblate spheroid.

SPHEROI'DAL CONDITION of liquids is the name usually given to a series of very singular phenomena discovered by Leidenfrost, but first carefully investigated by Boutigny. Indeed, one at least, of these phenomena has been popularly known for a very long time, being the foundation of the rough practical method of determining whether or not a flat-iron is so hot as to be likely to singe the linen to which it is to be applied. The test consists simply in letting a drop of water fall upon the iron; if it be not too hot, the drop spreads over the surface and evaporates. If it be too hot, the drop at once glances off the iron without wetting it.

The common experimental method of exhibiting the spheroidal condition is easily performed thus: A metallic disc, slightly concave, like a watch-glass, is heated by a lamp, and water is cautiously dropped on it from a pipette. If this be done before the disc is sufficiently heated, the water boils almost explosively, and is dispersed at once in vapor. But, when the disc is hot enough, the water remains suspended, as shown in the cut, *above* the surface; and the drop, when small, takes nearly the form of an oblate spheroid. Various proofs have been given, though they are obviously unnecessary, that there is no contact in this case. Thus, if the disc be very nearly flat, light passes freely between it and the drop. Again, if one pole of a galvanic battery be connected with the disc, and the other be dipped into the drop, a galvanometer interposed in the circuit shows that no current passes. By heating the disc sufficiently, and dropping on the water very carefully, we may easily keep in the spheroidal state as much water as, if not more than, it could hold when cold. The explanation of the phenomenon is not yet quite clear; but there is no doubt that the radiant heat from the disc raises vapor so freely from the surface of the drop nearest it, as to interpose a cushion of dense and highly-heated vapor between them, on which the drop, as it were floats; the pressure of the vapor balancing its weight. This is not, however, a quite complete explanation of the experiment, and it would require too much detail to examine it more closely. But the most curious fact connected with the experiment is, that the water does *not* boil. In fact it evaporates so freely that the heat carried off from it, as latent heat, by the vapor which is constantly formed, keeps its temperature somewhere about 206° F. only. This suggests a curious experiment, which is found to succeed. *Boiling* water, dropped on a red-hot plate of metal, instantly assumes the spheroidal state, and is *cooled* six degrees below boiling.

It is not necessary that a metal plate be used—a watch-glass will suffice for the experiment; but *hot* water must be dropped on it, else the glass will crack.

Other liquids, and even some bodies which are solid at ordinary temperatures, can be easily brought into the spheroidal state—the lowest requisite temperature of the disc being dependent on the boiling point of the substance. Thus, while water has a temperature of 206° F. in the spheroidal state, the disc must have a temperature of 340° F. at least—for alcohol, these temperatures are 168° F. and 270° F.—for ether, 94° F. and 140° F. A good example of a solid entering this state is furnished by dropping crystals of iodine on a hot platinum disc.

It is not necessary that the disc should be solid; it is easy to obtain ether, and even water, in the spheroidal state over the surface of hot oil—but great care is required, as explosions are apt to occur, in which case the hot oil is freely thrown about.

Many cases of bursting of steam-boilers, otherwise apparently inexplicable, seem to be attributable to this condition of matter. Thus, if we suppose that the water-supply has run low, and the boiler has been overheated, it is conceivable that the contents may sometimes be in the spheroidal state. The addition of cold water, in such a case, would bring them suddenly *in contact with* the overheated metal, and large quantities of steam would be generated with violence.

A very singular experiment, the freezing of water on a red-hot plate is easily performed by the help of this property of matter. Liquid sulphurous acid is so volatile as to have a temperature of 13° F. only, when in the spheroidal condition. As this is 19 under the freezing-point of water, if a little water be dropped into the spheroid of acid, it is at once frozen, and the pellet of ice can be dropped on the hand from the still red-hot plate.

Even mercury can be frozen by a similar process, but as much greater cold is required, the substance in the spheroidal state is a mixture of solid carbonic acid and ether.

The hand may be dipped for a short time with impunity into melted lead, and even into melted copper. The vapor, instantly raised from the moisture of the skin, prevents, so long as that moisture lasts, more than an endurable amount of radiant heat from reaching the hand, and also prevents direct contact. It is probable that a knowledge of some forms of this phenomenon, in old days, was employed by priestcraft for the purpose of protecting, when it was desirable to do so, the victims of the Ordeal (q. v.) by fire.

The phenomenon may easily be reversed. Thus, a red-hot silver ball, dropped into a vessel of water, is seen to glow for some time, till it has so far cooled, that the water comes into contact with it, when we have, as in the other form of the experiment, an immediate and violent formation of vapor. The success of this experiment is greatly aided by the addition of some strong ammonia to the water.

SPHI'NCTER MUSCLES (Gr. *sphinkter*, that which binds tight) are circular bands of muscular fibres, whose function is to antagonize the expellent action of certain viscera, especially the bladder and the lower part of the intestinal canal. It is to the presence of these muscles that the higher animals owe the power of retaining for a considerable period the excrementitious matters collected in the bladder and rectum, and of discharging them at intervals, the sphincter muscles being like those engaged in the process of respiration, mainly, but not entirely under the control of the will. Under certain conditions, however, the necessity for expelling the contents of these viscera becomes so urgent that the sphincters lose their ordinary voluntary power.

SPHINX, a Greek word, signifying the Squeezer or Strangler, applied to certain symbolical forms of Egyptian origin, having the body of a lion, a human or an animal head, and two wings attached to the sides. Various other combinations of animal forms have been called by this name, although they are rather griffins or chimæras. Human-headed Sphinxes have been called androsphinxes; one with the head of a ram, a criosphinx; with a hawk's head, a hieracosphinx. The form, when complete, had wings added at the sides; but these are of a later period, and seem to have originated with the Babylonians or Assyrians. In the Egyptian hieroglyphs, the Sphinx bears the name of *Neb*, or Lord, and *Akar*, or Intelligence, corresponding to the account of Clemens, that these emblematic figures depicted intellect and force. The idea that they allegorized the overflow of the Nile when the sun was in the constellations Leo and Virgo, appears quite unfounded. In Egypt, the Sphinx also appears as the symbolical form of the monarch considered as a conqueror, the head of the reigning king being placed upon a lion's body, the face bearded, and the usual dress-drapery being suspended before it. Thus used, the Sphinx was generally male, but in the case of female rulers, the figure has a female head, and the body of a lioness.

The most remarkable Sphinx is the Great Sphinx at Gizeh, a colossal form, hewn out of the natural rock, and lying 300 feet

View of the Great Sphinx during the excavations of Caviglia, 1816.
From Colonel Vyse's *Pyramids of Gizeh*.

east of the second pyramid. It is sculptured out of a spur of the rock itself, to which masonry has been added in certain places, to complete the form, and measures 172 feet 6 inches long by 56 feet high.

Immediately in front of the breast, Caviglia found, in 1816, a small naos, or chapel, formed of three hieroglyphical tablets, dedicated by the monarchs Thothmes III. and Ramesses II. to the

Sphinx, whom they adore under the name of Haremakhu, or Harmachis, as the Greek inscriptions found at the same place call it —i. e., the Sun on the Horizon. These tablets formed three walls of the chapel; the fourth, in front, had a door in the center, and two couchant lions placed upon it. A small lion was found on the pavement, and an altar between its fore-paws, apparently for sacrifices offered to it in the time of the Romans. Before the altar was a paved esplanade or dromos, leading to a staircase of thirty steps placed between two walls, and repaired in the reigns of M. Aurelius and L. Verus, on the 10th May 166 A.D. In the reign of Severus and his sons, 199—200 A.D., another dromos, in the same line as the first, and a diverging staircase, were made, while some additions were found to have been made to the parts between the two staircases in the reign of Nero. Votive inscriptions of the Roman period, some as late as the 3d c., were discovered in the walls and constructions. On the second digit of the left claw of the Sphinx, an inscription, in pentameter Greek verses, by Arrian, probably of the time of Severus, was discovered. Another metrical and prosaic inscription was also found. In addition to these walls of unburnt brick, galleries and shafts were found in the rear of the Sphinx, extending northwards. The excavations, however, of M. Mariette, in 1852, have thrown further light on the Sphinx, discovering the peribolos, or outer wall that encircled it; that the head only was sculptured; and that the sand which had accumulated round it was brought by the hands of man, and not an encroachment of the desert; also that the masonry of the belly was supported by a kind of abutment. To the south of the Sphinx, Mariette found a dromos, which led to a temple built, at the time of the fourth dynasty, of huge blocks of alabaster and red granite. In the midst of the great chamber of this temple were found seven statues, five mutilated and two entire, of the monarch Shaf-ra or Cephren, made of a porphyritic granite. They are fine examples of ancient Egyptian art. While the beauty and grandeur of the Great Sphinx have often attracted the admiration of travelers, its age has always remained a subject of doubt; but these later discoveries prove it to have been a monument of the age of the 4th dynasty, or contemporary with the pyramids.

Besides the Great Sphinx, avenues of Sphinxes have been discovered at Saqqarah, forming a dromos to the Serapeium of Memphis, and another dromos of the same at the Wady Esseboua. A Sphinx of the age of the Shepherd dynasty has been found at Tanis, and another of the same age is in the Louvre; and a granite Sphinx, found behind the vocal Memnon, and inscribed with the name of Amenophis III., is at St. Petersburg. An avenue of criosphinxes has been found at Karnak. These are each about seventeen feet long, and of the age of Horus, one of the last monarchs of the 18th dynasty. Various small sphinxes are in the different collections of Europe, but none of any very great antiquity.

The Theban Sphinx, whose myth first appears in Hesiod, is described as having a lion's body, female head, bird's wings, and serpent's tail, ideas probably derived from Phœnician sources, which had adopted this symbolical form into the mythology from Egypt. She was said to be the issue of Orthos, the two-headed dog of Geryon, by Chimæra, or of Typhon and Echidna, and was sent into the vicinity of Thebes by Juno, to punish the transgression of Laius, or, according to other accounts, by Bacchus, Mars, or Pluto. See ŒDIPUS. The Sphinx was a favorite subject of ancient art, and appears in bas-reliefs, on medals of Chios and other towns, and often as the decorations of arms and furniture. In Assyria and Babylonia, representations of Sphinxes have been found, and the same are not uncommon on Phœnician works of art.

SPHINX. See HAWK-MOTH.

SPHY'GMOGRAPH, an instrument by which we ascertain, and permanently record, the form, force, and frequency of the pulse-beat, and the changes which that beat undergoes in certain morbid states. This instrument consists of two essential parts: (1) Of two levers, one of which is so delicately adjusted on the vessel the pulsation of which it is desired to examine, that on each expansion of the vessel the lever undergoes a corresponding slight elevation: this lever communicates by a perpendicular arm with a second, to which it transmits the impulse received from the vessel; the extremity of this second lever is armed with a pen-point, which records the movements thus indicated on a movable plate, controlled by the second part of the instrument. (2) The second portion consists of a plate, moved by watch-work, and bearing a strip of paper on which the *sphygmographic* tracery is formed.

Mode in which the Tracery is formed.—As the pulse transmits through the levers a vertical movement to the pen-point, and the plate, on which the tracery is formed, is moved steadily across the pen-point, an undulating line (fig. 1) is the result: the *height*

Fig. 1.

of the elevations indicating the strength of the pulse; and the *number* of the elevations delineated in the time the pen takes to travel, its frequency. Figs. 1, 2, and 3 are fac-similes of sphygmographic tracings: of these, fig. 1 is the tracing presented by a natural pulse; figs. 2 and 3 are morbid. The latter are excellent examples of the tracings produced by the pulse at the wrist in two common forms of cardiac disease, and exhibit the manner in which the tracing is modified in diseased states of the circulatory system. Fig. 2 represents the pulse of a patient suffering from

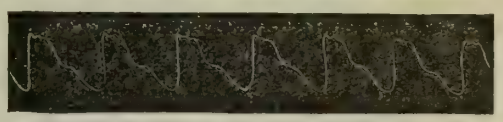

Fig. 2.

an incompetent state of the valves guarding the orifice of the aorta, the great vessel conveying blood from the heart. The blood, in such a case, when propelled into the aorta, distends it, and communicates a pulse throughout the arterial system. When the vessel again contracts, regurgitation takes place into the cavity of the heart, as the valves, which should prevent this regurgitation, and maintain the arterial tension, are unable to perform their function. The pulse-beat is accordingly abrupt, and of short duration, and the sphygmographic tracing presents a series of abrupt elevations and depressions. Fig. 3 represents the pulse met with in a differ-

Fig. 3.

ent form of cardiac disease, in which the valves are so affected as to obstruct the passage of the blood into the circulation: the effect of this on the pulse is to render its beats weakly marked and irregular; and in the sphygmographic tracing, the elevations are diminished in height and regularity. The pulse, in extreme forms of this lesion, is represented in sphygmographic tracing by a slightly waving line.

SPHYRÆ'NIDÆ, a family of fishes included by Cuvier in *Percidæ*, but having the ventral fins far behind the pectorals, and the bones of the pelvis quite detached from those of the shoulder. The form is elongated; there are two dorsal fins; the scales are small and cycloid; the mouth very large, with strong sharp teeth. The species are found in the Mediterranean and in tropical seas. Some attain a large size, as the BARRACOUDA, or Barracouda Pike (*Sphyræna barracouda*), an inhabitant of the tropical parts of the Atlantic Ocean, which is scarcely less formidable than the White Shark It is, however, held in considerable estimation as an article of food, but at some seasons of the year becomes unwholesome. It is a beautiful fish, of a rich green color above, and white beneath. The BECUNA (*S. vulgaris*) is also valued as an article of food, and its scales and air-bladder yield a substance used for making artificial pearls.

SPICCA'TO (Ital. separated), a musical term, indicative, like *Staccato* (q. v.), of a distinct and detached mode of performance. Its usual application is to music for bowed instruments, where it implies that each note is to have a bow distinct from that which precedes or follows it.

SPICE ISLANDS. See MOLUCCAS.

SPICES (Lat. *species*, kinds; in later Latin, kinds of goods, or produce in general; and then, the most highly prized kind of goods, the aromatic productions of the East), aromatic and pungent vegetable substances, used as condiments and for flavoring food. They are almost exclusively the productions of tropical countries. In ancient times, and throughout the middle ages, all the spices known in Europe were brought from the east; and Arabia was regarded as the land of spices, but rather because they came through it, or were brought by its merchants, than because they were produced in it, for they were really derived from the further east. They owe their aroma and pungency chiefly to essential oils which they contain. They are yielded by different parts of plants; some, as pepper, cayenne pepper, pimento, nut-

meg, mace, and vanilla being the fruit or particular parts of the fruit; whilst some, as ginger, are the root-stock; and others, as cinnamon and cassia, are the bark. Tropical America produces some of the spices, being the native region of cayenne pepper, pimento, and vanilla; but the greater number are from the East Indies.

SPIDER (*Aranea*), a Linnæan genus, now divided not only into many genera, but into many families, and constituting a section (*Araneida*) of the class *Arachnida*, and order *Pulmonaria*. The species are very numerous, and are found in all parts of the world, but most abundantly in tropical countries, which also produce the largest species, some of them capable of making very small birds, and not merely insects, their prey (see BIRD-CATCHING SPIDER). The *cephalothorax*, formed by the combination of the head and thorax into one piece, is covered with a kind of horny buckler, generally of an oval form; the abdomen is at-

Position of Spider when attached to a thread of web, and spinning apparatus highly magnified.

tached to it by a short stalk, and is generally soft and tumid. Each of the eight legs consists of seven joints, the last armed with two hooks, which are commonly toothed like a comb. The *frontal claws*, commonly called *mandibles*—which do not, however, correspond to the mandibles of insects, and move in an entirely different direction, up and down—are terminated by a sharp movable hook, which has near its extremity a small slit for the emission of a venomous fluid secreted in a gland of the previous joint. The *maxillæ* are two in number, and between them is an organ called the *tongue*, forming part of the external apparatus of the mouth. The maxillæ are the basil joints of the *palpi*, which resemble very small legs, and are often terminated in the females by a small hook, but in the males by complicated and curious appendages, characteristic of the different genera and species. Spiders have generally eight eyes, the relative position of which varies remarkably in the different families and genera. A few species have only six eyes, and a very small number have only two. The upper surface of the abdomen generally exhibits a number of impressed spots, most conspicuous in those kinds which have a smooth naked skin. The pulmonary orifices are either two or four in number, and are situated near the base of the abdomen. Near the anus are several *spinnerets*, small protuberances, pierced at the extremity with a multitude of minute orifices, from which threads of extreme tenuity are produced, all these threads combining to form one thread of the *web*.

The substance which exudes from the spinnerets is glutinous, and immediately dries into thread on coming in contact with the air. It is elaborated in reservoirs, which terminate in intestine-like tubes. All spiders have spinnerets, and produce threads although all do not use them for the same purposes; for they differ very much in their habits: some employ their webs in order to catch their insect prey, whilst others depend for the capture of their prey on their powers of running and leaping; and some weave for themselves habitations, in which they live, whilst others select holes and crevices as their place of abode. Almost all spiders envelop their eggs in silken cocoons, which some of them tear open when the young are hatched; they are attentive to their young, some carrying them for a time on their back, whilst some carry the cocoons or egg-cases beneath their breast, and others carry them attached to the extremity of the abdomen. Nearly 2000 eggs have been found in a single cocoon, and the young, when set free, may be seen swarming over the body of the mother, so as almost to conceal her from view. The female S. is, in many of the species, much larger than the male, and a very remarkable danger attends the amatory approaches of the latter, as, if they are not favorably received, he is not uncommonly killed and eaten on the spot. Spiders are very pugnacious, and in their combats often sustain the loss of limbs; but like crustaceans, they possess the power of repairing this loss. Like them also, they change their skin frequently during their growth; but they undergo no proper transformation. There is much similarity of form among all the multitude of kinds. Many of them exhibit very brilliant and beautiful colors, among which are some of the British species, to be found in fields and moors, although the Common House S. (*Aranea domestica*) is of very unattractive appearance.

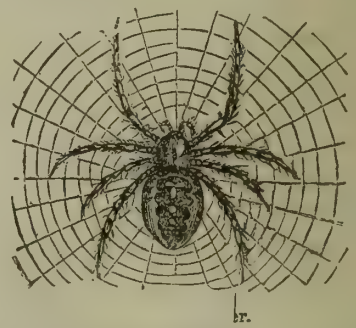
All spiders kill the insects and other small creatures on which they prey by means of their venomous mandibles, and the bite of a house S. is quickly fatal to a house-fly. The bite of the larger species is dreaded even by man, being very painful, and not only producing much inflammation and swelling, but often much fever. Death has been known to ensue.

Spider's webs have long been in high repute for stanching wounds. Threads of this material are also employed for the cross-wires of astronomical telescopes. Textile fabrics have been made of it, but only as articles of curiosity.

Spiders have been arranged by Walcknaer in five principal groups, distinguished by their habits. (1.) *Hunting Spiders*, which incessantly run about in the vicinity of their abode in quest of prey, some of them weaving silken tubes, in which they dwell, others hiding in fissures; some remarkable for the swiftness with which they run, others for their power of leaping in order to seize their prey. Some of them are of large size. Livingstone mentions a South African one which can leap a distance of one foot. A small one is common on windows in Britain in summer, and, when leaping, avoids the danger of falling from the window by suspending itself at the same moment by a thread. (2.) *Wandering Spiders*, which have no fixed residence, have the power of

Various species of Spiders.

running sideways or backwards, and throw out threads to entrap prey, but do not weave them into regular webs. Some of them live among plants, and place their egg-cases on leaves, the edges of which they bind together with their silk. (3.) *Prowling Spi-*



Geometric Spider.

ders, which have nests, but prowl about in their neighborhood, or in that of the threads which they spread to catch prey.

(4.) *Sedentary Spiders*, such as the common house S., which spin large webs, and lie in wait at the middle or at the side. These are subdivided according to the fashion and structure of their webs. (5.) *Water Spiders*, which resemble the last group in their habits, except that they live in water, generally among the stems and leaves of aquatic plants, where they construct their webs. A very interesting species, one of the most interesting possible inmates of an aquarium, is the Common Water S. (*Argyroneta aquatica*) of Britain, not unfrequently to be found in deep ditches and ponds in some parts of England. It is of a brownish color, densely covered with hairs, which are of great importance in its economy, entangling air, which the animal carries down with it into the water, to supply its pulmonary sacs; for the water spiders all breathe by the same kind of organs as their terrestial congeners. The eggs of the water S. are attached to the leaves or stems of plants under the surface of the water, and are protected by a dome-shaped web, so close in its structure as to retain the air which is brought into it, and in which the S. itself lives, bringing down air on its furred body till the dome is filled. The entrance

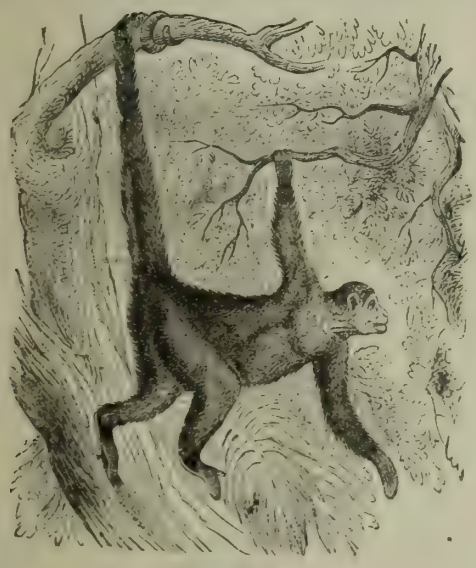
is from below.—The most curious nests are those of the Trap-door Spiders, belonging to the group *Territelariæ*, or underground weavers. The nest is a tubular burrow, lined with silk, and having the entrance covered with a circular lid of the same material attached to the edge of the lining by a kind of hinge. In the most common form of nest, the lid is made thick by having layers

Trap-door, open

of earth between the layers of silk, and fits like a cork into the mouth of the tube, which is bevelled to receive it. As mosses grow on the lid as well as on the surrounding ground, the concealment is complete. In some types of nest, there is a thin external door, and then one of a more solid kind some inches below, behind which the inmate can place itself, and resist the intrusion of an enemy. In one kind of these double-door nests, a side-gallery branches off from the main one, and the external door is so placed at the angle, that it can be made to shut either.

SPIDER FLY (*Ornithomyia*), a genus of dipterous insects, closely allied to the Forest Fly (q. v.), but the claws of the tarsi having three instead of two teeth; and the species are parasitical on birds, never on quadrupeds. *O. avicularia* frequently infests the common fowl, the blackcock, and other birds in Britain. It is greenish-yellow, with smoke-colored wings.

SPIDER MONKEY, a name often given to species of the genus *Ateles*, small American monkeys, on account of their very long, slender, inelegant limbs. The tail is very long, and not only prehensile in the highest degree, but endowed with a wondrous sensitiveness of touch. These monkeys display great intelligence. It is their common practice to break nuts by means



Spider Monkey.

of stones; and a tame one which Dr. Gardner carried with him in his travels in Brazil, used to try a larger stone, if the first did not serve its purpose, and even to take it up in both paws, and dash it upon the nut, jumping quickly out of the way to avoid injury to its own toes. This animal generally rode on the back of a large mastiff, and in descending a steep hill, would curl its tail round the root of the mastiff's tail, to make its seat secure.

SPIEGELEISEN. See BESSEMER PROCESS; also KRUPP'S STEEL.

SPIGE'LIA, a genus of plants of the natural order *Loganiaceæ*, having a calyx glandular inside, a long slender valvate corolla, long filaments, and a capsule of two *cocci*, splitting around at the base.—*S. Marilandica*, often called WORM GRASS and CAROLINA PINK, is a native of the southern United States, a perennial plant with a simple quadrangular stem. The root (PINK ROOT) is purgative, narcotic, and poisonous, but is a powerful vermifuge, and is very commonly employed in the U. S.—*S. Anthelmia*, an annual, native of tropical America, with very small purplish flowers, in spike-like racemes, possesses similar properties. The efficacy of both is, however, impaired by keeping; and they are apt to produce unpleasant symptoms when used as medicines. Other species are also known as poisons.

SPIKE, in Botany, that kind of inflorescence in which sessile flowers, or flowers having very short stalks, are arranged around an axis, as in the greater plantain, common vervain, common lavender, and some species of sedge. In rye, wheat, barley, darnel, and many other grasses, there is a sort of compound spike, that is, the flowers or fruits are arranged together in spikelets, upon short stalks, which again surround the top of the culm in the form of a spike. The catkin, the spadix, and the cone may be regarded as varieties of the spike.

SPI'KENARD, or NARD (Gr. *Nardos*), a perfume highly prized by the ancients, and used both in baths and at feasts. It was brought from India, and was very costly. The 'ointment of spikenard' (John xii. 3) was probably an oil or fat, impregnated with the perfume. The plant which produces it has been ascertained by the researches of Sir William Jones and Dr. Royle to be the *Nardostachys jatamansi*, the Jatamansi of the Hindus, a small plant of the natural order *Valerianaceæ*, a native of the mountains of the north of India, and found at least as far south as the Deccan. It grows on the Himalaya to an elevation of 18,000 feet, and its roots are a favorite perfume in Tibet and Nepaul. The ladies of Nepaul use oil in which the root has been steeped for perfuming their hair. The odor is not, however, generally agreeable to Europeans. The root, which is from three to twelve inches long, sends up many stems, with little spikes of purple flowers, which have four stamens.—The name spikenard was given by the ancients to perfumes used as substitutes for the true or Indian spikenard, some of which were derived from the roots of plants of the same natural order, the kind called Gallic or Celtic spikenard from those of *Valeriana Celtica* and *V. saliunca*, which are still used in the East for perfuming baths; and that called Cretan spikenard from those of *V. Italica*, *V. tuberosa*, and *V. phu*. All of these grow on the Alps and other mountains of the south of Europe, and the peasantry of Styria and Carinthia collect them from rocks on the borders of perpetual snow. They are tied in bundles, and sold at a very low price to merchants, who sell them at a great profit in Turkey and Egypt, from which they are partly transmitted even to India. About sixty tons are annually exported from Trieste.

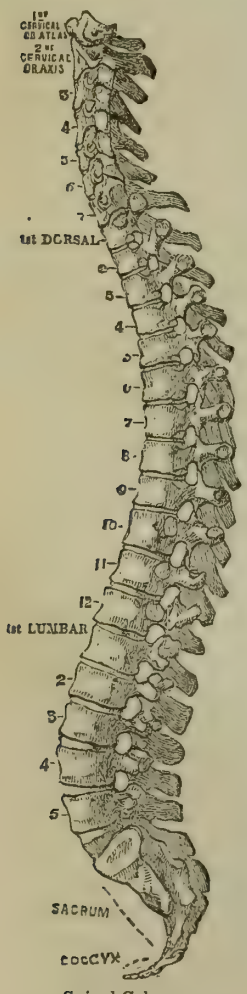
SPIKING is the operation of rendering a cannon useless without the expenditure of much time and labor. It is resorted to by troops compelled to abandon their own ordnance, or unable to remove pieces of the enemy's which they have captured. The process consists in driving a nail or spike into the vent or touchhole. To remove it, it is recommended, if an iron gun, to load with double charge and double balls, and to fire by a train laid through the muzzle. This is supposed to loosen the spike. If the gun be of brass, a few drops of sulphuric or nitric acid on the touchhole will render it practicable to extract the spike. If these methods fail, nothing remains but the tedious process of drilling out the spike or boring a new vent.

SPI'NA BI'FIDA is a congenital malformation, occurring perhaps more frequently than any other except hair-lip, and arising like it from arrest of development. It may be regarded as a congenital hernia of the membranes of the spinal cord, through a fissure in the wall of the bony canal. A tumor is thus formed, which is usually of a roundish shape, varying in size from that of an egg to that of an adult head, lying in the middle line of the back, fluctuating, and adhering to the adjacent vertebræ either directly or by a pedicle. The usual termination of the disease is death. As the size of the tumor increases, fatal convulsions ensue; or the skin investing the tumor may ulcerate, and the contents escape, in which case palsy or convulsions produce death. Occasional cases are, however, recorded in which patients with this affection have survived till middle life. Active surgical treatment usually hastens death, and should only be resorted to in the most urgent circumstances. Moderate support by means of a hallow truss, or a well-padded concave shield, may tend to keep the disease stationary; and any interference beyond this is, in the great majority of cases, unadvisable.

SPI'NACH, or SPINAGE (*Spinacia*), a genus of herbaceous plants, of the natural order *Chenopodiaceæ;* dicœcious, the male flowers consisting of a 4-parted perianth and four stamens; the female, of a 2—3-cleft perianth, and a germen with four styles; the perianth hardening around the fruit as it ripens; the fruit an achenium. COMMON S., or GARDEN S. (*S. oleracea*), is in general cultivation for the sake of its young leaves, which are a favorite and wholesome vegetable, either prepared by boiling, or by frying with a little butter. Two very distinct varieties are cultivated.—PRICKLY S., which has the leaves somewhat triangular and

arrow-headed, and the fruit rough with prickle-like projections; and SMOOTH S., or ROUND S. (*S. glabra* of some botanists), with the leaves more round and blunt, and the fruit smooth. S. is an annual. Its stem rises to the height of from two to four feet; the male flowers are in long spikes, the female in clusters close to the stem. After the stem begins to be developed, the leaves become bitter, and unfit for use. This bitterness appears also at an earlier period in dry weather, or in poor soil; and the more luxuriantly that S. grows, the better it is. It is sown in spring, and is ready for use in a very short time; or it is sown in autumn, thinned out, and used early in spring. The Smooth S. is very generally preferred for the former purpose, and the prickly kind for the latter; but a somewhat intermediate variety, called Flanders S., is now often used for both, being particularly esteemed for the large size of its leaves. The native country of S. is not well known, but it is believed to be in some part of Asia, as the plant was introduced by the Arabs into Spain, and thence diffused over Europe.—Another species (*S. tetrandra*) is cultivated, and much esteemed, in India.—The name S. is also given to a number of other plants of very different botanical characters, but which have the same bland and nutritious qualities, and are used in the same way.—NEW ZEALAND S. is *Tetragonia expansa*, a plant of the natural order *Mesembryaceæ*, sub order *Tetragonieæ* (nat. ord. *Tetragoniaceæ* of Lindley), a trailing, succulent annual, spreading widely over the surface of the ground, and producing a great abundance of stalked ovate-rhomboid leaves. The young stems and leaves of this plant are much used in New Zealand, and have now come into very general use also in other parts of the world, as a kind of spinach. It is cultivated in the middle and south of Europe and in Britain, succeeding well even in Scotland with the slightest aid of a hotbed in spring.—PATIENCE DOCK, or GARDEN PATIENCE (*Rumex Patientia;* see DOCK), is called in Germany ENGLISH S., and was formerly much cultivated in England, but is now neglected.

SPINAL COLUMN, or SPINE, THE, is the most important and characteristic part of the skeleton of the highest animal subkingdom, which includes Mammals, Birds, Reptiles, Amphibians, and Fishes. In each of these classes, it is composed of a series of bones placed one above, or in front, of another, and called Vertebræ (q. v.); and hence, these animals, having this distinguishing characteristic in common, are all included in the term *Vertebrates*. The vertebræ vary greatly in number in different animals, and even in members of the same class, and the number have no apparent relation to the other organs of the animal. Moreover, in their shape, they differ extremely even in different parts of the same spine, in accordance with their special functions. In man, the number of vertebræ which collectively form the spinal column is 7 in the neck (cervical vertebræ), 12 in the back (dorsal vertebræ), 5 in the loins (lumbar vertebræ), all of which are capable of being detached from one another, and are termed *true* vertebræ; and 5 vertebræ ossified together, and forming the sacrum, and 4 or 5 similarly united forming the termination of the column, and constituting the bone called the coccyx, which are known as *false* vertebræ. However long or short the neck may be, every mammal has 7 cervical vertebræ, excepting the three-toed sloth, which has 9, and the sea-cow, which has 6. In the other regions of the spine, no such law exists. Each vertebra is attached to the two between which it lies by numerous strong and more or less elastic ligaments, and between each pair of vertebræ there is interposed a lenticular disc of fibro-cartilage, which acts as a buffer. By these arrangements, the spinal column is rendered highly elastic, the communication of jars or shocks is prevented, and a very considerable general range of movement permitted, although the motion between any two adjacent vertebræ is slight.



Spinal Column.

The elasticity of the column is further increased by the component vertebræ being arranged in curves, instead of being placed perpendicularly. The curves should be exactly in the antero-posterior direction, any well-marked lateral deviation from the perpendicular being abnormal; but a very slight lateral curvature with the convexity to the right may often be detected in the upper and middle parts of the back, and is supposed to be dependent on the more frequent use and greater strength of the right arm as compared with the left. From their position, they are termed the cervical, dorsal, lumbar, and pelvic curves. The dorsal and pelvic curves have their concavities in front, and thus enlarge the spaces in which the thoracic and pelvic viscera are contained; the two other curves are, convex anteriorly, and thus afford support to the parts above them. The upper three curves are so arranged that their chords are in the same vertical line in the erect position of the body, and this vertical line corresponds with the line of gravity of the head. The cause of these curves is to be sought for partly in the shape of the vertebral bodies, and partly in that of the intervertebral substance. Amongst the uses of these curves it may be mentioned (1) that they enable the spine to bear a greater vertical weight than it could otherwise maintain; it is calculated that nine times as great a vertical force is required to bend it as if it had been straight; (2) that they facilitate the movements of the body, especially in the act of running; and (3) that they are so disposed as to protect the cord in movements of the spine. Similar curves are seen in the spine of other mammals, though the degree of flexure is liable to great deviations. The lumbar curve, which has especial reference to the erect position, is always much less marked than in man.

The vertebral canal formed by the apposition of the spinal foramina, or neural arches (see SKELETON), and containing and protecting the spinal cord, varies in its size at different parts of the column. It is largest in its antero-posterior diameter in the neck and loins (measuring at the last lumbar vetebra ¾ths of an inch), where the antero-posterior movements of the spine are greatest, and where the cord is least closely attached to the vertebræ; while in its lateral diameter it is greatest at the atlas, where it measures nearly an inch and a half. A transverse section of the canal is nearly circular through the greater part of the back. The intervertebral foramina through which the nerves emerge vary in shape and position in different parts, but are always of sufficient size to prevent injurious pressure on the nerves during movement of the spine; and in the dorsal region, which is the ordinary seat of angular curvature, the nerves are so protected by bony arches, that they may escape injury, even when the bodies of several dorsal vetebræ have been destroyed by ulceration.

SPINAL CORD or MARROW, THE STRUCTURE AND FUNCTIONS OF. The spinal cord is that elongated part of the cerebro-spinal axis (see NERVOUS SYSTEM) which is contained in the spinal canal from the *Foramen magnum*, at the base of the skull, superiorly, to the first or second lumbar vertebra inferiorly, where it merges into the *Filum terminale*, which extends to the lower end of the sacral canal, and in no way differs structurally from the proper spinal cord, except that no nerve-roots are connected with it. The membranes by which it is protected from danger, and kept in its proper position, are described in the article NERVOUS SYSTEM.

Its length varies from 15 to 18 inches, and it presents a difference in its diameter in different parts, there being an upper or cervical, and a lower or lumbar enlargement. In form it is a flattened cylinder. It is almost completely divided, along the median plane, by an anterior and posterior fissure, into two equal and symmetrical parts. The anterior fissure is more distinct and wider at the surface than the posterior fissure, but it only penetrates to about one-third of the thickness of the cord, while the posterior fissure extends to about half the thickness of the cord. The two halves are hence only united near the center by a commissural band, which is traversed by the 'spinal canal' (fig. 2, *f*), extending downwards from the fourth ventricle (see BRAIN), and about one-hundredth of an inch in diameter. A posterior and an anterior lateral furrow (two shallow depressions, the latter being scarcely perceptible) further divide each half of the cord into a posterior, a lateral, and an anterior column; these two furrows corresponding with the lines of attachment of the posterior and anterior nerve-roots.

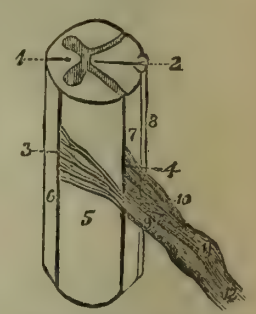


Fig. 1.—Side View of the Spinal Cord, showing the Fissures and Columns.

1, anterior median fissure; 2, posterior median fissure; 3, anterior lateral fissure; 4, posterior lateral fissure; 5, lateral column; 6, anterior column; 7, posterior column; 8, posterior median column; 9, anterior root; 10, posterior root; and 11, ganglion of (12) a spinal nerve.—From Gray's *Human Anatomy*.

The separation of the antero-lateral columns into the 'anterior' and the lateral columns (A, A, and L, L, in fig. 2), is made more

obvious internally by the mode in which the gray or vesicular nervous matter (described and figured in the article NERVOUS SYSTEM) is arranged in relation to the white or fibrous matter. Although the distribution of the gray matter differs considerably in different parts of the cord, it usually presents in a transverse section the form of two somewhat crescent-shaped masses, whose convexities are turned towards each other, and are connected by the gray commissure, while their cornua are directed towards the

Fig. 2.—Magnified View of Transverse Section of the Spinal Cord through the middle of the Lumbar Enlargement: showing, on the right side, the course of the Nerve-roots, and on the left, the position of the principal tracts of Vesicular Matter.

A, A, anterior columns; P, P, posterior columns; L, L, lateral columns; *a*, anterior median fissure; *p*, posterior median fissure; *b*, *b*, *b*, *b*, anterior roots of spinal nerves; *c*, *c*, *c*, *c*, posterior roots; *d*, *d*, tracts of vesicular matter in anterior column; *e*, tracts of vesicular matter in posterior column; *f*, spinal canal.—After J. L. Clarke.

surface of the cord; the posterior peak on each side nearly reaches the posterior lateral furrow, while the anterior, though the larger cornu, does not approach quite so near the surface at the assumed anterior furrow. The enlargement of the cord in the cervical and lumbar region, where the great nervous plexuses are given off, is chiefly due to the increase, at those points, of gray matter, which is comparatively deficient in the interval between them.

The white substance seems to increase regularly from the lower to the upper part of the cord; and this fact, as Dr. Carpenter remarks, seems to indicate the probability that the longitudinal columns serve (as formerly supposed) to establish a direct connection between the encephalic centers and the roots of the spinal nerves. Careful microscopic investigation has revealed the fact, that the root-fibres of the spinal nerves run two very distinct courses in the substance of the cord; the first *transverse*, and the second *longitudinal*. The transverse fibres traverse the cord horizontally or obliquely, and appear to pass out in the other sets of roots connected with the same segment, either on its own or on the opposite side of the median fissure; while the longitudinal fibres in part connect the posterior roots directly with the posterior column without passing into the vesicular matter, but for the most part enter the gray matter, and emerge from it into the posterior column, or into the posterior part of the lateral column of the same or the opposite side. How far these longitudinal fibres run up or down the cord, is undecided. It is probable that *some* of them are longitudinal commissures, serving to connect the nerve-roots of one segment of the cord with the vesicular matter of another above or below it, and it is possible that *all* are of this character, in which case the spinal cord will be the real center of all the nerve-fibres connected with it.

In considering the functions of the spinal cord, we have to regard it in two distinct points of view—viz., in the first place, as a *conductor* of nervous force between the nerve-trunks and the brain; and in the second place, as an *independent nervous center*. As a mere *conductor* of nervous force, its functions and behavior are the same as those of a nerve trunk; for, as Dr. Carpenter observes, 'if it be divided, all the parts of the body which are solely supplied by nerves coming off below the point of section are completely paralyzed, as far as regards sensibility and voluntary movement; no impressions made upon them having the least power to affect the consciousness, and no exertion of the will being able to determine contraction of the muscles. This state of *paraplegia*, which may be experimentally induced in animals, is frequently exhibited in man, as a result of injury or of disease that seriously implicates the spinal cord; and as it has been shown that among the lower animals complete reunion of the cord may take place after complete division, as indicated by the entire restoration of its functional powers, and the complete redintegration of its structure, so have we reason to believe that a similar regeneration may take place, to a considerable extent, in man, this being marked by a gradual return of sensibility and power of voluntary movement in the lower limbs, which had been at first completely paralyzed.'—*Human Physiology*, 6th ed., pp. 529, 530. There can be little doubt that the gray matter is essentially the conductor of *sensory* impressions, for if the anterior, posterior, and anterolateral columns are divided as completely as possible, the gray substance remaining uninjured, the sensibility of the parts below is unaffected; while, conversely, if the gray substance is divided, while the white columns remain uninjured, sensibility is almost totally extinguished.

M. Brown-Sequard, whose researches on the nervous system are of the highest importance, has shown that the central portions of the gray substance are the most effective in the transmission of sensation. He likewise brings forward strong evidence to prove that there are special conductors in the spinal cord for the sensations of touch, pain, temperature, and muscular contraction, none of which can convey other sensations than their own. Notwithstanding its singular power of conducting sensory impressions, the gray substance is itself insensible. Amongst his other remarkable discoveries in connection with this subject, Brown-Sequard has found, that on dividing one-half of the spinal cord of an animal, not only is anæsthesia (or loss of sensation) established on the opposite side of the body, but there is also produced a state of hyperæsthesia (or exalted sensibility) on the same side, which begins to appear a few hours after the operation, and continues in dogs for about 20 days, in cats about 14 days, and in guinea-pigs for many months, after which the sensibility falls below its usual standard. With regard to the conduction of *motor* impulses, there is great uncertainty. Considerable differences have been shown to exist in the position of the motor tracts in different parts of the cord, and Brown-Sequard concludes from his experiments on the effects of section, that while in the dorsal region, all parts, except the posterior columns, are employed in the conveyance of the orders of the will to the muscles, in the upper part of the cervical region, most of these conductors are in the lateral columns and in the gray substance between these and the anterior column.

We have now to consider the spinal cord as an *independent nervous center*. The simplest, and, at the same time, the most decisive evidence of the independent power of the spinal cord, is derived from the motion exhibited by the limbs of animals when irritation is applied to them after section of the cord at some point above the entrance of their nerves; the fact that these movements are reflected through the cord, and do not result from direct stimulation of the part irritated, being shown by their complete cessation when the nerve-trunks are divided. Thus, if a frog be pithed by dividing the cord between the occipital foramen and the first vertebra, an unusual convulsion takes place while the knife passes through the nervous center; but this quickly subsides, and if the animal be placed on the table, it will resume its ordinary position. It is quite unable to move by any voluntary effort; but if a toe be pinched, the limb is instantly drawn up, and seen to push away the irritating agent, and then draw up the leg again to the old position.

From these and other experiments, we may conclude (1) that the spinal cord, *in union with the brain*, is the instrument of sensation and voluntary motion to the trunk and extremities; and (2) that the spinal cord may be the medium for the excitation of movements, *independently* of volition or sensation, either by direct irritation of its substance, or by the influence of a stimulus conveyed to it from some surface of the trunk or extremities by its nerves distributed upon that surface.—For further information on this subject, the reader is referred to Todd and Bowman's *Physiological Anatomy and Physiology of Man*, 2d ed., vol. i.; Carpenter's *Human Physiology*, 8th ed. 1876; and the other standard works on Physiology.

SPINA'ZZOLA, a city of Southern Italy, in the province of Bari, 7 miles south of Minervino. Pop. 10,000. The country around is very fertile, and produces grain in abundance.

SPINDLE TREE (*Euonymus*), a genus of plants of the natural order *Celastraceæ*. This order contains about 260 known species, all small trees or shrubs.—The genus *Euonymus* has a lobed capsule, and seeds surrounded by an aril, which in some of the species is remarkable for its brilliancy of color. The Common Spindle Tree (*E. Europæus*), a native of Britain, chiefly of the southern parts, and of great part of Europe, is very ornamental when in fruit, and its aril is of a fine orange color. It is a shrub rather than a tree. The wood is hard and fine-grained. It is used for the finer articles of turnery, and for skewers. It was formerly used for making musical instruments and for spindles, whence the name of the shrub. In Germany, the shoots are bored

for tubes of tobacco-pipes. Charcoal made of it is much valued for crayons.

SPINE, or THORN, in Botany, is a sharp-pointed projection of the wood of a stem or branch, and essentially differs from a Prickle (q. v.) in being connected with the wood, and covered with bark. A spine is, in fact, a branch arrested in its growth and modified. In some trees and shrubs, as in the sloe, branches which bear leaves often terminate in the form of a spine. Cultivation, or whatever tends to increase the luxuriance of a plant, diminishes the tendency to produce spines. The name spine is also given to the sharp extremities of the midrib of leaves, and to the sharp angular projections of the margin of hard leaves, as in the holly. In some plants, the stipules are metamorphosed into spines.

SPINE, CURVATURE OF THE. There are two perfectly distinct forms of curvature, viz., LATERAL CURVATURE—arising from weakness of the bones, ligaments, and muscles, and fearfully common in girls of the middle and upper classes, between the ages of 10 and 16—and ANGULAR CURVATURE (frequently known as POTT'S CURVATURE, or the MALADY OF POTT, in consequence of that eminent surgeon having been the first to describe its true nature), which consists of caries of the bodies of the vertebræ, and is by far the more serious affection of the two. '*Lateral Curvature*, or *Distortion*, denotes deformity of the bones of the spine and chest; with corresponding change of the structures in relation to them. It is called "lateral," from the spine being curved sideways; and to distinguish it from "angular" deformity, in which the spine is directed from behind forward, owing to excavations in its forepart from caries.' The above definition is taken from Mr. Shaw's article on this affection in Holmes's *System of Surgery*, vol. iv. p. 844, an article from which we have borrowed freely in relation to the symptoms and causes of the disease. The first thing that commonly attracts attention is a projection of one scapula, or an elevation of one shoulder, generally the right; the right shoulder and right side of the chest being unnaturally high and rounded, while on the left side, the shoulder is depressed, and the side of the chest concave. On examination, the spine is found to have acquired a spiral appearance, 'not unlike what might have been produced if it had been taken, when soft, at both ends by the two hands, and twisted as a a washerwoman wrings a wet cloth.'—Shaw *op. cit.* In advanced stages of the distortion, the dorsal curve increases abruptly to such an extent as to render it angular, the attending contortion being similarly abrupt, This condition gives rise to various changes, including a *humped* appearance, a great displacement of the ribs, a diminution of the cavity of the chest, and a proportionate wasting of the lung. In consequence of these physical changes, the patient can no longer walk in a simple and natural manner, but exhibits a halting, jerking awkward gait.

The following may be noticed amongst the principal causes of lateral curvature: 1. The suppleness of the spine in the young, its structures being then more gristle than bone, and the column virtually immature. 2. Weakness of the muscles, which are seldom properly exercised in girls of the age and class in which this disorder occurs. This muscular debility is usually followed by deterioration of the bones and their ligaments, and this, apart from other obvious and direct bad effects, tends to make all the component parts of the spine—vertebræ and articulations—more prone to yield to the superincumbent weight, and to become distorted. These evil results are increased by prolonged stooping. When we enter a school, shortly before the breaking up of the class, we usually find most of the pupils standing or sitting in a tired lounging position. They are instinctively relieving the pain of over-fatigue by throwing the weight on the insensible fibrous structures, and thus relieving the aching muscles. When such attitudes are long indulged in, the ligaments undergo a process of over-stretching, and a general looseness of the vertebral joints is the result. By standing on one leg, or, more correctly speaking, by throwing all the weight of the body on one foot, the body is kept upright with the least possible expenditure of muscular power. Hence, a weak and fragile girl is induced to adopt this position. Too long indulgence in this habit will, to a certainty (for anatomical reasons, into which we have not space to enter), aggravate existing curvature, and induce it, if it did not pre-exist.

However slight a curve in the spine of a young girl may be, it ought to be deemed of importance; for when the column inclines laterally even to a slight degree, the superincumbent weight ceases to be supported on the line of the vertical axis, and falls on the oblique processes of the side to which she leans; and these processes becoming rapidly diminished in length by absorption, induced by this abnormal pressure, general distortion rapidly commences. With regard to the final issue of a case, distortion beginning at the age of ten is more dangerous than at fourteen, because the disease runs a more rapid course in the younger cases. A cure is, for the same reason, more easily effected in the younger patient. If the patient's age be beyond sixteen, little can be done beyond checking the further progress of the deformity.

Before discussing the treatment of these cases, it is necessary to say a word regarding an important preventive measure. When a girl is defective in muscular power, disinclined to take exercise, and prone to distortion of the spine, the sitting position does not afford her rest, in consequence of the great efforts she has to make in order to keep the body erect. A patient in that condition will derive benefit from being obliged to lie for two or three hours daily, at divided intervals, on a sofa or board. When the deformity has actually occurred, gymnastic exercises suggested by the medical attendant will not unfrequently, when continued for some time, have the effect of loosening the connection of the bones, of facilitating their falling into their proper places, when extension is employed, and of restoring to the spine a portion of its lost suppleness. Mr. Shaw suggests the following simple plan for attaining the same end. 'Let the patient lie on one side, with a firm cylindrical pillow, six inches in diameter, placed under the gibbosity of that side, and let her rest her weight on the pillow: the effect will be to counteract and reverse the curve. The same may be done alternately on the two sides. The posture may be continued each way for a quarter of an hour at a time, and be repeated twice or thrice daily.'—*Op. cit.*, p. 858. There are two methods of extending the curved spine—viz. (1), by stretching the body while the patient is recumbent; and (2) by letting the patient remain upright, and using spinal supports. As each method has its own advantages, a combination of them will often afford the best results. The chief objections to the former are the necessary confinement, comparative seclusion, and interference with the routine of study. Any mode of treatment with the view of producing extension of the spine must be continued for months in order to be of any avail. It would be altogether out of place to notice in this article the various extending beds, apparatuses for exercise, and different kinds of spinal supports that have been devised by surgeons and anatomical mechanicians, and we will merely observe that mechanical supports must be tried with great caution. They are always more or less irksome to bear, and if they are not doing good, are almost sure to be doing harm. On this subject, the reader may consult Heather Bigg's work entitled *The Spine and Upper Extremities.*

Angular Curvature consists, as already mentioned, of caries of certain vertebra, which first consumes the bones and fibro-cartilages, and subsequently excites a discharge of pus. The first symptom of this affection is the appearance, at the seat of the caries, of a prominence of one or more of the spinous processes. This 'growing out' of the back, as patients frequently term it, is due to the destruction of a portion of the column. In an advanced stage, the spinal ridge will stand out prominently, the knob of each process being distinctly visible; and finally, a distinct angular projection is developed. The *consequences* of this disease are thus summed up by Druitt. '1. In favorable cases, the diseased bones collapse, and are anchylosed; abscesses, if they form, are healed, or their matter is absorbed, and the patient recovers in two or three years, with more or less deformity, which is, of course, incurable. 2. In some fatal cases, the patient dies suddenly from two or three of the diseased vertebræ giving way, and crushing the spinal cord; or from dislocation of the odontoid process; owing to ulceration of its ligament; or from the bursting of abscesses into the spinal cord; or from their bursting into the pleura or peritoneum; but more frequently death is caused by slow irritation and exhaustion, consequent on the formation of psoas or lumbar abscesses.'—*The Surgeon's Vade-mecum*, 8th ed., p. 348. The most essential point in relation to *treatment* is *rest*, and the most effectual method of arresting motion between the diseased vertebræ, and of keeping them at rest, is by placing the patient in a recumbent position on his back. If possible, an invalid bed should be procured, provided with contrivances for enabling him to lie upon it, day and night, without rising. Local counter-irritants, such as compound tincture of iodine, are often useful; and good diet, backed, if necessary, by cod-liver oil and tonics, must be prescribed. In conclusion, sufferers from any form of real or suspected spinal disease are earnestly warned to avoid the numerous quacks, whether in or out of the medical profession, who have taken up the spine as a specialty.

SPI'NEL, a mineral allied to corundum, consisting chiefly of alumina, with smaller proportions of magnesia, silica, and protoxide of iron. It occurs in crystals, which are often octahedral, and is chiefly found in Ceylon and Siam. Its colors are various; red, blue, green, and black. It is much prized as a gem; red spinels are commonly called rubies; the *Balas Ruby* is a rose-red S., and a violet colored S. is known as *Alamandine Ruby*.

SPI'NET (Ital. *spinetta*), an old-fashioned stringed musical instrument with a keyboard, smaller and weaker than the harpsichord, and like it, one of the precursors of the pianoforte. Each note had but one string, which was struck by a quilled jack acted on by one of the finger-keys. The strings were placed horizontally

and nearly at right angles to the keys, as in the square piano-forte; and the general outline of the instrument nearly resembled that of a harp laid in a horizontal position, with the keys occupying the position of the sounding-board; on which account the spinet, when first introduced, was called the couched harp.

SPINNING is the art of combining animal and vegetable fibres into continuous threads fit for the processes of weaving, sewing, or rope-making. The most primitive spinning apparatus is the spindle and distaff, representations of which are to be seen on the earliest Egyptian monuments. The distaff was a stick or staff upon which a bundle of the prepared material was loosely bound, and which was held in the left hand or stuck in the belt; the spindle was a smaller tapering piece to which the thread was at-

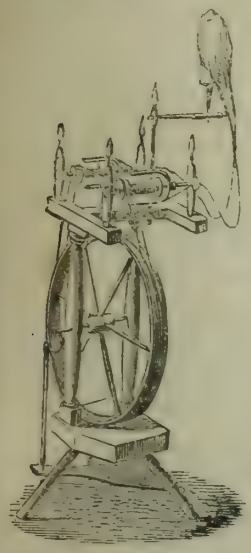

Fig. 1.—Two-handed Spinning-wheel.

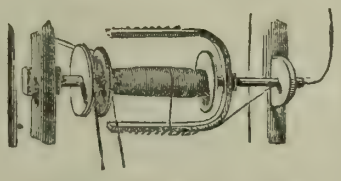

Fig. 2 —Spindle, Bobbin, and Winding-arm on a larger scale.

tached. By a dexterous twirl of the hand the spindle was made to spin round and at the same time recede from the spinster, who drew out between the forefinger and thumb of the right hand a regular stream of fibres so long as the twisting of the spindle lasted. It was then drawn in, the new length of the thread wound upon it, and the operation was renewed. An obvious improvement on this was to set the spindle in a frame and make it revolve by a band passing over a wheel driven either by occasional impetus from the hand or by a treadle; this constituted the *spinning-wheel*, which is said to have been invented in Nuremberg as recently as 1530. In the spinning wheel in its most improved form, and as used for flax, a bobbin or 'pirn,' with a separate motion, was placed on the spindle, which had a bent arm—a flyer or flight—for winding the yarn on the bobbin. The spindle and bobbin revolved at different rates, the revolutions of the spindle giving the twist, and the difference of the rate causing the winding on. The two-handed wheel had two spindles and pirns a little apart, with the distaff or 'rock' stuck into the frame between them, and the spinster produced a thread with each hand. The spinning of flax on such wheels for the manufacturer was an important branch of domestic industry in the northern counties of Scotland as late as 1830, if not later.

Neither the spinning-wheel nor the hand could spin more than one, or at most two threads at a time, and therefore, with the rapid increase of population, and the improvements made in the process of Weaving (q. v.), they became quite inadequate to supply the demand for yarn: but an accident, it is said, about the year 1764, led to an invention by which eight threads could be spun at once; and this was soon improved upon until eighty could be produced as easily. This was the invention of the *spinning jenny* for cotton spinning, by James Hargreaves, at Standhill, near Blackburn in Lancashire. In this machine, a number of large reels of cotton formed into a thickish coil, called a *roving*, were set on upright fixed spindles, and the ends of the rovings were passed between two small movable bars of wood placed horizontally and under the control of the spinner, who could thus make them press more or less on the roving, and consequently increase or decrease the draw upon it from the spinning spindles, which were set in a row at the other end of the frame, and all capable of being set in motion simultaneously by the wheel. The success of the spinning-jenny (fig. 3) was considerable, but its history has been too often told to be required here; and even previous to its invention, a better idea had been started and acted upon by others, and was afterwards brought to such perfection, that the invention of Hargreaves soon passed into obscurity.

In order to understand the operations of spinning as now practised, and as improved by the invention alluded to, it is desirable, in this place, to say a few words upon the preparation of the fibres for the process of spinning. In the first place, if wool or cotton, it has to be 'opened;' that is, it must be relieved from its original knotted and lumpy condition; this was formerly done by hand, but is now easily managed by machines called 'willows or willeys,' 'blowers' and 'openers.' By the first of these, which consists of a drum covered with small spikes moving in a hollow cylinder, also lined with spikes, but so arranged that those on the drum pass close to, but do not come into collision with them as it revolves, the cotton or wool is fed in on one side, is dragged forward by catching on the spikes, and is delivered at an opposite opening to that by which it entered, in a loose state and free from knots. It is not, however, quite loose enough for the subsequent operations, and it is more or less mingled with impurities. It is therefore taken to the 'blower' or 'opener,' and being put into a shaft, is there

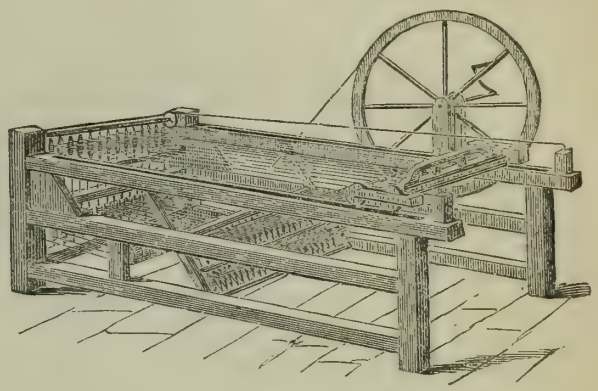

Fig. 3.

acted upon by a stream of air violently driven in by machinery, which blows it forward, removes extraneous matters, and so separates the fibres that they pass out at the other end in an exceedingly light flocculent state and ready for being formed into *laps*. This operation consists in laying the material very equally on an endless apron made of small bars of wood, and of the width of the frame of the machine in which they are placed. This apron (*a*, fig. 4) passes round two rollers, placed at a little distance apart,

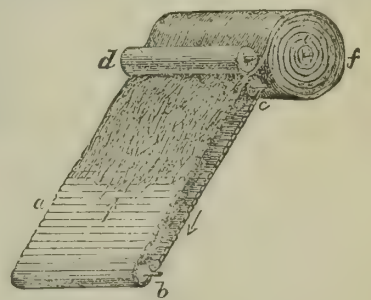

Fig. 4.

as in fig. 4, *b*, *c*, the rollers being moved by machinery. The arrows indicate the direction in which the apron moves; and as the operator covers its entire surface with a thin layer of the fibre, it passes under the roller *d*, and is taken on to the roller *e*, in the form of a compressed layer of cotton or wool, called a *lap*. When the roller *e* is full, it is removed, with its lap *f*, to make way for another. Much care is taken in weighing out and distributing the material of these laps, because upon this first operation the ultimate size of the yarn depends.

The laps are taken to the *carding-machine*, consisting of a series of cylinders revolving in a frame, and placed so close together that they almost touch each other. Each cylinder is covered with a coating of fine steel wire points, which are stuck in leather, or some other flexible material, and are technically called *cards*. The production of these cards by machinery is in itself a marvel, and the automatic machines for making them are wonderfully effective. Each piece of wire is bent as in fig. 5, and is put through two holes in the leather, as in fig. 6; *a* shows a bent wire going in, and *b*, *b*, wires completely in the holes in leather, *c*, *c*, *c*, so as to form two points on the other side, and these are slightly bent all in one direction, as in fig. 7, where the piece of card *a* is seen cut through at *b*, to show the direction given to the wires *c*. There are many variations upon this arrangement of the wires, but the general principle is the same in all. The machine

Fig. 5.

for making the cards cuts the wire to the right lengths, bends them, pierces the holes in the leather, inserts the wires, and finishes by giving them the slight sloping direction which is essential.

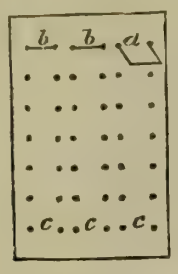

Fig. 6.

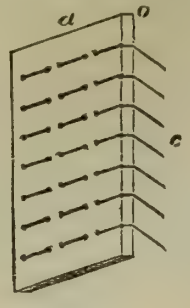

Fig. 7.

The lap is made of the same width as the cylinders of the carding-machine, and is so adjusted that, as it unwinds from its roller, it passes in between a pair of the carding cylinders, the steel wire teeth of which seize hold of the individual fibres, and drag them in one direction until they are caught by other cylinders, and so carried from one to another, always being pulled in a straight direction until they are laid as nearly as possible side by side, and are given off in a thin cobweb-like film at the last cylinder, where it is prevented from continuing its journey round the cylinders by a small bar of metal called the *doffer*, which, with a gentle and peculiar motion, removes it from the cylinder.

The film of fibre is of the same width as the cylinder of the carding-machine, but it is gathered together by the operator, who passes it through a smooth metal ring, and between two small polished rollers, the revolutions of which carry it forward, and deposit it in a deep tin can in the form of a loose untwisted column of cotton or wool, about an inch in thickness which is called a *sliver*. A small portion of this arrangement is shown in fig. 8, which represents a carding-machine with only two carded

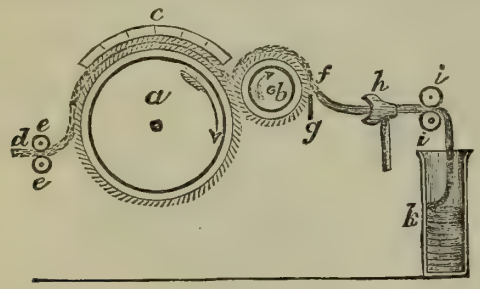

Fig. 8.

cylinders, *a* and *b*; they are, however, much more numerous. There is also a concave piece of carding, *c*, which was formerly much used, but has lately given way to additional cylinders, but it makes the action more apparent in a drawing; *d* is the lap drawn on by the action of the two small rollers *e, e*, which slightly press it as they revolve. It is quickly distributed allover the surface of the large cylinder *a* by means of its numerous wire-teeth; and as it passes the roller *b*, the teeth of which move in an opposite direction, as indicated by the arrows, the fibres are caught off the large, and are carried round the small cylinder until they reach *f*, where they are stripped off by the doffer *g*, and are passed through the ring *h*, and the rollers *i*, *i*, into the tin receiver *k*. The sliver is now in the first stage of spinning; it has next to be drawn out very gradually until it is not thicker than a quill; and in drawing it out, the operator gives it a very slight twist, still leaving it so loose in structure that it will break with a slight touch; in this state it is called a *roving;* and it was at this stage that the spinning-jenny began to operate upon it. The rovings, which were wound as they were drawn upon large reels, were unwound by the machine, and were still further drawn out and firmly twisted and wound on to spindles or cops, the drawing being regulated by the pressure of the wooden bars of the jenny, which was within reach of the operator's hand.

The *throstle-machine*, patented by Arkwright in 1769, had for its object the drawing of the rovings through a succession of pairs of rollers, each pair in advance of the others, and moving at different rates of speed. The first pair receive the sliver, compress it, and pass it on to the second pair, which revolve at a greater speed, and thus pull it out to exactly the number of times greater length that their revolutions exceed those of the other pair—in number it is usually eight times—and as the first roving is passed through a second, third, and sometimes fourth machine, the finished roving is 32 times longer than the sliver. As the roving issues through the last rollers of each machine, it is received on *spools* or *reels*, calculated to hold a given quantity; and these are transferred to the *spinning-frames*, which resemble the *roving-frames*. Here the roving takes the place of the sliver; and as it unwinds from the spool, is drawn through successive pairs of rollers, moving as before at different rates, each succeeding pair faster than the backward ones, so that the roving gets thinner and thinner, until the tenuity is carried as far as desirable. It is then carried on to a spindle which revolves with great rapidity; and by means of a simple arrangement, is made both to twist the thread and wind it on the spindle ready for the weaver.

This system produces too great a strain upon the thread in its progress to admit of its being drawn so fine as is wanted for many purposes, and this led to the invention of the *mule-jenny* by Crompton (q. v.) in 1779, which has a travelling frame upon which the spindles are set. This frame is now made long enough to carry hundreds of spindles, and it gently draws out and twists the thread after it leaves the last pair of rollers; and when it has reached its limits—now several yards, but in Crompton's time only five feet—it rapidly returns, winding up the spun thread on the spindles as it goes back. These machines are now applied, with various necessary modifications, to cotton, wool, flax, silk, and other textile materials, and the effect they have exerted upon our manufactures is more wonderful than anything in the whole history of commerce. Previous to the invention of the mule, few spinners could make yarn of 200 hanks to the pound (the hank being always 840 yards). At the same time, the natives of India were weaving yarn of numbers ranging between 300 and 400. Now, however, our manufacturers have reached such extraordinary perfection, that Manchester spinners have made No. 700, which was woven by a French firm. No. 10,000, a pound of which would reach 4770 miles, has been made to test machinery. The most modern machines combine in one the operations of carding, roving, and spinning.

SPINOLA, Ambrosio de, Marquis, a famous soldier, was born at Genoa in 1569, his father being a noble. He took service with Spain, and in 1603 became chief commander of the Spanish army in the Netherlands. He took Ostend in 1604, Julich in 1622, and Breda in 1625. He afterwards commanded Spanish troops in Italy, and died at the siege of Casale in Piedmont, 25th September 1530.

SPINOZA, Baruch (= *Benedict*), one of the greatest philosophers of modern times, was born at Amsterdam on the 24th of November 1632. His parents, rich Portuguese Jews, had their son diligently instructed in the Bible and its commentaries, and the Talmud. But after having mastered both, and imbibed the philosophical spirit of such commentators as Aben Ezra, he was allowed—the more readily that his sickly constitution unfitted him for a commercial career—to devote himself entirely to a life of study. Physical sciences and the writings of Descartes, to which he turned first of all, very soon drew him away from the rigid belief and practices of the synagogue; and Saul Levi Morteira, his talmudical teacher, who had built the fondest hopes upon the genius of his pupil, was the first to threaten him with the direst punishment if he did not retract the rank heresies that he began openly to utter. S., after a time, entirely withdrew from the the community of his brethren, who formally excommunicated him. A fanatic even attempted to frighten him by an either real or feigned attack upon him as he left the theater one night. At that period the young truth-seeker made the acquaintance of the young and beautiful daughter of Van den Ende, his master in Greek and Latin, and fell passionately in love with her, but was rejected. From that time forth, Philosophy became the sole aim and object of his life. In accordance with the teachings of the sages of the Mishna, S. had, apart from his studies, made himself master of a mechanical craft. He had learned the art of polishing lenses. This now became the means of his subsistence. Besides, he was also an expert in the art of design, and among a number of other portraits, he drew one of himself in the dress of Masaniello.

When 28 years old, he left Amsterdam, and went to Rhynsburg, near Leyden, where he wrote the *Abridgment of the Meditations of Descartes*, with an Appendix—the latter being the first cast, so to say, of his *Ethics*. The year following, he removed to Woorburg, near the Hague, and shortly afterwards, yielding to the solicitations of his, by this time, numerous friends, he removed to the Hague itself. The Elector of the Palatinate, Charles Lewis, next offered him a vacant chair at the university of Heidelberg, with 'full liberty of teaching,' provided he would not say aught to prejudice the established religion, i. e., Christianity; whereupon S. declined the both lucrative and honorable professorship. His small pittance was enough to satisfy his wants. In a similar way, he refused generous offers made to him by wealthy friends, like Simon de Vries, who intended to bestow a large sum of money upon him. All he could be prevailed upon to accept was a small annuity of a few hundred florins; the rest he persuaded his gen-

erous friend to bestow upon his (De Vries') own brother. An offer of a pension, on the condition of his dedicating a work to Louis XIV., he rejected with scorn. His domestic accounts, found after his death, show that he preferred to live on a few pence a day, to being indebted to another's bounty. He died, 44 years old, on the 21st of February 1677. Throughout his life of study, of abstemiousness, of bodily and mental suffering—for his constitution was undermined no less by consumption and overwork, than his sensitive mind was wrought upon by the violent severance of all natural ties of affection, to say nothing of the misery of occasional want and of perpetual persecution—no complaint ever passed his lips. Simplicity and heroic forbearance, coupled with an antique stoicism and a childlike, warm, sympathizing heart, were the principal attributes of him who was nicknamed epicurean and atheist by his contemporaries. It has well been said, that no man, perhaps, was more filled with religion than S., and that to be an epicure at the rate of twopence-halfpenny a day cannot be a very serious crime.

Respecting S.'s Philosophical system, of which we can only give the very faintest of outlines here, it must be premised that it developed itself on the basis of Descartes. The latter had inaugurated a new epoch by his 'reconstruction' of knowledge. Dissatisfied both with the dogma and the scepticism around him, he cleared the ground by first doubting everything, and then laying a new foundation by *Cogito, ergo sum* (I think, I therefore am). S., however, deeply struck both with the reasonings and conclusions of Descartes, took his 'I think, therefore I am,' merely as a starting-point to prove more clearly the existence of God than Descartes did. The consciousness of man's own existence and of his imperfect state, are not, he thinks, sufficient to solve the grand problem. He therefore, assumes, first of all, three fundamental things, which he calls respectively Substance, Attributes, and Mode. By substance he understands, like Descartes, that which needs nothing else to its existence; but, unlike Descartes, he assumed only One such substance—God. Yet this term is not to be understood in the ordinary sense, for S.'s God neither thinks nor creates. There is no real difference, he holds, between mind, as represented by God, and matter, as represented by Nature. They are One, and according to the light under which they are viewed, may be called either God or Nature. The visible world is not distinct from him. It is only his visible manifestation, flowing out of him, who is the last fountain of life and essence, as a finite from the infinite, variety from unity—a unity, however, in which all varieties merge again. Extension and thought, which, with Descartes, had been two Substances, with S. becomes 'Attributes;' that which the mind *perceives* as *constituting* Substance. Extension is visible Thought; Thought is invisible Extension.

The relation between Substance and Attributes, S. illustrates by the example of an object—colorless in itself, perhaps—seen through yellow or blue spectacles. And this explains the relation between body and mind, and the complete unity between them. The mind is the idea of the body—i. e., the same thing considered under the attribute of thought. The *modus* or *accidens* is only the varying form of Substance. Like the curling waves of the ocean, they have no independent existence; nay, less than these are they things of reality; but they are simply the ever-varying shapes of the Substance. Substance, thus, is the only really existing, all-embracing essence, to which belongs every thing perceptible to our senses, and not perceptible. Thus, every thought, wish, or feeling, is a Mode of God's Attribute of thought; every thing visible is a Mode of God's Attribute of extension. God is the 'immanent idea,' the One and All. 'World' does not exist as world—i. e., as an aggregate of single things—but is one complex whole and one peculiar aspect of God's infinite Attribute of extension. The variety we behold in things is a mere product of our faulty conceptions, particularly of, as S. terms it, our 'imagination,' which perceives unity as a complex of multiplicity.

On these metaphysical speculations he founds his Ethics, which he deduces in a mathematical form, after the method of Euclid. The chief doctrines are: The absence of free-will in man—himself only a *Modus* dependent on causes without, and not within him. Will and Liberty belong only to God, who is not limited by any other Substance. Good and evil are relative notions, and sin is a mere negative; for nothing can be done against God's will, and there is no idea of Evil in Him. Utility alone, in its highest sense, must determine the good and the evil in our mind. Good, or useful, is that which leads us to greater reality, which preserves and exalts our existence. Our real existence is knowledge. Highest knowledge is the knowledge of God. From this arises the highest delight of the spirit. Happiness is not the reward of virtue, but virtue itself; and this is to be attained by a diligent following in God's ways. Sin, evil, negation, &c., are merely things that retard and obstruct this supreme happiness.

S.'s system, Pantheism or Atheism, as it has been variously called, appears to be nothing but the most rigid, most abstract Monotheism that can be conceived by man. There is only Substance, only God—nought else. It was not unnatural, however, that this system should be misunderstood either as materialism or as pantheism, seeing the word 'substance,' which, with S., means 'existence,' is, in ordinary language, associated with the idea of matter or body. Be this as it may, 'this most iniquitous and blasphemous human invention,' as it has been called for 200 years, has become the acknowledged basis of modern German philosophy; and pious theologians like Schleiermacher did not hesitate to apply the highest terms of 'pious, virtuous, God-intoxicated,' to S., who, we need not add it, never left Judaism, although he left the synagogue and its human formalities.

His principal works are—*Renati Descartes Principiorum Philosophiæ, Pars I. et II., more geometrico demonstratæ* (Amsterdam, 1663); *Tractatus Theologico-politicus* (anonymous 1670); the *Opera Posthuma*, edited in the year of S.'s death by Ludwig Meyer, contain: *Ethica Ordine Geometrico Demonstrata, Tractatus Politicus, Tractatus de Intellectus Emendatione, Epistolæ, Compendium Grammatices Linguæ Hebrææ.* Several minor treatises are lost; but the lately discovered *Tractatus de Deo et Homine*, published in 1862, is a most valuable addition to our materials for tracing the development of S.'s system. The literature on the Spinozistic philosophy is very copious, especially in Germany. S.'s life has even been made by Auerbach the subject of two romances. The best editions of S.'s works are those of Paulus (1802–3) and Bruder (1843–6). See Pollock's *Spinoza* (1880).

SPIRÆ'A, a genus of plants of the natural order *Rosaceæ*, and of the sub-order *Spirææ*, in which the fruit consists of five or fewer capsular carpels distinct from the calyx, and each containing 1—6 seeds. The genus S. has one or more follicular, many-seeded carpels. It contains a large number of species, natives of Europe, Asia, and America, herbaceous plants and low deciduous shrubs; of the herbaceous species, two are natives of Britain, DROPWORT (*S. Filipendula*), and MEADOW SWEET or QUEEN OF THE MEADOW (*S. Ulmaria*), both with interruptedly pinnate leaves and flowers in cymes. Dropwort is a native of dry upland pastures; it is tonic and fragrant; and its tubers, which are somewhat nutritious, are in Sweden ground and made into bread. Meadow Sweet is well known for the powerful fragrance of its flowers. A fragrant distilled water is prepared from them. A North American species (*S. tomentosa*), called HARDHACK in the United States, is there used as a tonic and astringent. Many of the shrubby species are frequently planted for ornament.

SPI'RAL, in Geometry, is the name given to a class of curves which, during their gradual regression from a point, wind round it repeatedly. Their equations are generally expressed in terms of polar co-ordinates, and are all necessarily of the form $r = f(\theta)$, where θ never signifies a function of the angle, but the angle itself or a multiple of it. Several such curves have received distinguishing epithets, either on account of the properties they possess, or from their inventors; the chief of them are—the *equable spiral* or the *spiral of Archimedes*, whose equation is $r = a\theta$, and which, commencing at the origin, circles round and regredes from it with unvarying uniformity; the *hyperbolic* or *reciprocal spiral* ($r = a$); the *logarithmic* or *equiangular spiral* ($r = ab^{\theta}$); which recedes from the center or origin with a velocity increasing as the distance, and always cuts the radius vector at the same angle; &c.

SPIRAL VESSELS are those very delicate air-tubes in the cellular tissue of plants which run unbranched through the different parts of the plant, and whose walls are composed of fibres spirally or circularly twined. Spiral vessels are either *free*, when their windings are unconnected with each other, or *net-like*, when the windings are involved with each other in a net-like manner. If the free spaces between the convolutions in the latter are linear they form *lined* vessels; but if they are point-like, they form *punctate* or *porose* vessels. Spiral vessels, whose walls are formed of distinct horizontal rings, placed simply one above another, are called *annular* vessels. Spiral vessels seldom occur singly, but are generally united by cells into bundles called vascular bundles. These vascular bundles are scattered in the stems of endogenous plants; but in the stems of exogenous plants they are arranged in one or more concentric circles. Amongst cryptogamous plants, the ferns alone (in the most extensive signification of the term) are provided with spiral vessels. All plants which have spiral vessels are called *Vascular Plants*, in contradistinction to *Cellular Plants*, whose substance consists of cells only.

Through the operation of what laws the spiral form is assumed by spiral vessels, is still unknown, although the question has naturally been regarded as having an intimate connection with the tendency to spiral structure manifested in plants, and even in some of those cryptogamous plants in which no true spiral vessels are found; a tendency which is observed not only in spiral stems, spiral tendrils, the spiral fibres of the elaters of *Jungermanniæ*, and the like, but throughout the vegetable kingdom generally in the spiral arrangement of leaves and of the organs which are formed by the metamorphosis of leaves. The whole subject is an

extremely difficult one; there has been much speculation about it, but as yet with no satisfactory results.

SPIRE, a very acute pyramidal roof in common use over the towers of churches. The history of spires is somewhat obscure, but there is no doubt that the earliest examples of anything of the kind are the pyramidal roofs of the turrets of Norman date. Those of St. Peter's, Oxford (fig. 1), and Rochester Cathedral (fig. 2), are good specimens of circular and octagonal spires on a small

1, Turret, St. Peters's Church, Oxford; 2, Turret, Rochester Cathedral; 3, St. Mary's Church, Cheltenham; 4, Bayeux Church, Normandy.
(From Parker's *Glossary of Architecture*.)

scale. Spires of this early period are much lower than those of later date. The early English style has spires of acute form over the larger towers. They are generally what are termed broach spires, i. e., the slopes spring from the cornice of the tower without any parapet, and at the point where the square changes to the octagon, there is a small set-off or separate roof. (Fig. 3, St. Mary's, Cheltenham, indicates this arrangement.) Sometimes the angles at top of towers were occupied with pinnacles or sloping masses of masonry, as at Bayeux Cathedral, Normandy (fig. 4).

In the decorated style, the spires were more enriched, with a parapet and pinnacles at the top of the tower, crochets on the angles, and enriched windows.

The spires of the Perpendicular and Flamboyant styles are still more enriched, with flying buttresses at the angles, &c. They are sometimes perforated, and the sides of the spire filled entirely with tracery. Such spires are common in Germany, those of Strasbourg and Freiburg on the Rhine being very fine examples. As in the later styles generally, the character and beauty of the spire give place to dexterity in masonry, and many examples exist of traceried spires more wonderful than beautiful. See GOTHIC ARCHITECTURE.

Spires are most frequently constructed of stone, but they are also occasionally made of wood, and covered with lead, copper, slates, or shingles. These are chiefly to be found in localities where stone is scarce.

SPIRIT, a name of very general application to fluids, mostly of a lighter specific character than water, and obtained by distillation. Thus, the essential oil of turpentine is called Spirit of Turpentine. But in a stricter sense, the term spirit is understood to mean Alcohol (q. v.) in its potable condition, of which there are very numerous varieties, deriving their special characters from the substances used in their production.

SPIRIT DUCK. See GARBOT.

SPI'RITO SA'NTO. See ESPIRITU SANTO.

SPI'RITUALISM. Under the head of ANIMAL MAGNETISM, an account is given, from the scientific point of view, of some of those mysterious phenomena which, under the name of modern spiritualism, have recently attracted so much public attention. It is proposed here to give a more complete account of these phenomena as they appear to those who hold that they are inexplicable by the commonly received laws of physics.

That these phenomena in their higher phases—as those of trance, healing by touch, and subjection to the thought and will of another mind—are intimately allied with those of mesmerism, is obvious to all who have given any careful attention to them. Spiritualists, indeed, affirm that they differ only in this—that in the one case the operator is a mortal, in the other a disembodied human spirit possessing a spiritual body instead of a physical one. Those persons most readily susceptible to mesmeric influence generally prove to be the best mediums for spirit manifestation. Wherever mesmerism has been extensively practised, it would seem that the ground has thereby been prepared for the operators in the unseen world; and indeed, human magnetism is not unfrequently resorted to for this express purpose.

Many of the earliest and foremost advocates of spiritualism in England have traveled to spiritualism *viâ* mesmerism. As is fully shown in the correspondence of M. Billault and M. Deleuze, published in two volumes in 1836, the magnetists of France anticipated by at least half a century the revelations of what is now known as 'modern spiritualism,' which was as humble in its origin as other great movements recorded in history which have so largely influenced mankind.

In the village of Hydesville, New York State, lived Mr. John D. Fox and family, much respected by their neighbors as honest upright people. The two youngest children, Margaret, then twelve years old, and Kate, nine, were staying with their parents. Soon after they had taken up their residence here, in December 1847, they began to hear knockings in the house, which towards the end of March increased in loudness and frequency. Mr. Fox and his wife got up night after night, lit a candle, and thoroughly searched every nook and corner of the house, but discovered nothing. When the raps came on a door, Mr. Fox would stand ready to open it, the moment they were repeated, but though he opened the door on the instant, he could detect nothing, and no one was to be seen; nor could he obtain the slightest clue to the cause of these disturbances. But through all these annoyances Mr. and Mrs. Fox clung to the belief that some natural explanation of them would be found. Nor did they abandon this hope till the last night of March 1848.

Wearied out by a succession of sleepless nights, and of fruitless attempts to penetrate the mystery, the family had retired very early to rest; but scarcely had the mother seen the children safely in bed, and was retiring to rest herself, when the children cried out: 'Here they are again!' The mother child them, and lay down. Thereupon the noises became louder and more startling. Mrs. Fox called in her husband. The night being windy, it suggested to him that it might be the rattling of the sashes. He tried several, shaking them to hear if they were loose. Kate happened to remark that as often as her father shook a window-sash, the noises seemed to reply. Turning to where the noise was, she snapped her fingers, and called out 'Here, do as I do?' The knockings instantly responded. She tried, by silently bringing together her thumb and forefinger, whether she could still obtain a response. Yes! It—the mysterious something—could see, then, as well as hear! She called her mother: 'Only look, mother,' she said, bringing her finger and thumb together as before. And as often as she repeated the noiseless motion, just so often responded the raps. This at once arrested the mother's attention. 'Count ten,' she said; ten strokes were distinctly given. 'How old is my daughter Margaret?' Twelve strokes responded. 'And Kate?' Nine! 'What can all this mean?' was Mrs. Fox's thought. Who was answering her? Was it only some mysterious echo of her own thought? The answers to the next question she put seemed to refute this idea. 'How many children have I?' she asked aloud. Seven strokes. 'Ah!' she thought, 'it can blunder sometimes.' And then, aloud, 'Try again.' Still seven strokes as before Of a sudden a thought crossed her mind: 'Are they all alive?' she asked. Silence for answer. 'How many are living?' Six strokes. 'How many dead?' A single stroke; she had lost a child. Then she asked, 'Are you a man?' No answer. 'Are you a spirit?' It rapped. 'May my neighbors hear if I call them?' It rapped again. Thereupon she asked her husband to call a neighbor, a Mrs. Redfield, who came in laughing. But her mirth was soon changed. The answers to her inquiries were as prompt and pertinent as they had been to those of Mrs. Fox. She was struck with awe; and when, in reply to a question about the number of her children, by rapping four, instead of three, as she expected, it reminded her of a little daughter, Mary, whom she had recently lost, the mother burst into tears.

Of course a knowledge of these things could not be kept secret. The news soon spread, and the utmost excitement prevailed in the little village and beyond it. Neighbors flocked in, and the house was besieged and the time of the family wholly taken up with curious and eager visitors. Formal depositions appeared in more than one publication. The earliest of these, published April 1848—a pamphlet of forty pages—contains twenty-one certificates, chiefly given by the immediate neighbors. Most of the witnesses offer to confirm their statements, if necessary, under oath, and express their conviction that the family had no agency in producing the sounds.

It was found that these were more marked in the presence of Kate Fox, and in the hope of getting rid of these annoyances, Kate was sent on a visit to Mrs. Fish, a married sister, at Rochester. The only result being that, while the rappings did not cease at Hydesville, a new and more extended scene of operations was given them at Rochester, whither they followed Kate, and were found also to accompany her sister, and a girl who resided with them.

On one occasion, a visitor suggested that the alphabet should be called over, to see if the sounds would respond to the required

letters, and so spell out a communication. A shower of raps followed, as if to say: 'Yes, that is what we want!' The first message so given, was: 'We are all your dear friends and relatives.' Then the name of 'Jacob Smith,' Mrs. Fish's grandfather, was given. Previous to the spiritual telegraphy thus commenced, the only mode of communication had been by asking questions, one rap being understood as an answer in the negative, three in the affirmative, and two, doubtful, or that the answer could not then be given. It was now asked that a signal should be given when the alphabet was required; this was responded to by five strokes, which was henceforth understood as a call for the alphabet; and so a code of signals was instituted.

Similar demonstrations occurred about this time, independently, in the homes of some of the most respectable inhabitants of Rochester. At length it was communicated by the rapping that the facts should be given to the world, with a view to open up a more extended intercourse; and instructions were given as to where, how, and by whom, this was to be done. There was much difficulty in getting the parties named to take the responsibility, and incur the discredit and ridicule of this step: but their scruples were at length overcome; and on the 14th of November 1848, a public lecture, giving a simple narrative of the facts, was delivered in the Corinthian Hall, Rochester, to an audience of about four hundred people. The rappings, as had been promised, were distinctly heard in all parts of the hall; and a committee was appointed by the audience to investigate the subject, and report at a subsequent meeting. The committee all agreed that the sounds were heard; but they entirely failed to discover any means by which they were produced.

This result was very different to what had been confidently anticipated, and the dissatisfied audience, amazed at the failure, appointed a second committee, which it was expected would make such an investigation as could not fail to find out the trick; and when this committee, after the strictest investigation, only confirmed the judgment of its predecessor, the excitement became intense; and a third committee was appointed, consisting of those who had shown the most determined hostility to the reports of the previous committees, and who had expressed the utmost confidence in their ability to detect the imposition. It certainly was no fault of theirs that they did not. They resorted to every means their ingenuity could devise; but no fraud could be detected, no explanation given. The 'mediums' were separated, and their friends were rigorously excluded from the sittings of the committee. They were unexpectedly removed, first to one house, then to another. A committee of ladies divested them of their clothing; feather pillows were placed under their feet; the stethoscope was applied to see that there was no movement of the lungs by which the sounds could be made. Under every condition imposed, the obstinate raps came—on doors, floors, walls, ceiling; the place seemed alive with them. When this final committee, baffled and mortified, made known their failure, the meeting broke up in the greatest excitement and confusion. But the object was gained: the facts were reported and commented on in all the journals throughout the country.

Circles for investigation were now everywhere formed, and not only were the rappings obtained, but new phases of these strange phenomena were constantly developed. In *Forty Years of American Life*, by Thomas Low Nichols, M.D., we read: 'Dials were made with movable hands, which pointed out letters and answered questions without apparent human aid. The hands of mediums, acting convulsively, and, as they averred, without their volition, wrote things apparently beyond their knowledge, in documents purporting to be signed by departed spirits. Their writings were sometimes made upside down, or reversed so as only to be read through the paper or in a mirror. Some mediums wrote with both hands at a time, different messages, *without*, as they said, being conscious of either. There were speaking mediums, who declared themselves to be the merely passive instruments of the spirits. Some represented, most faithfully, it was said, the actions, voices, and appearance of persons long dead; others, blindfolded, drew portraits, said to be likenesses of deceased persons they had never seen—the ordinary work of hours being done in a few minutes. Sometimes the names of deceased persons, and short messages, appeared in raised red lines upon the skin of the medium. Ponderous bodies, as heavy dining-tables and pianofortes, were raised from the floor, falling again with a crash and jar. Tables on which several persons were seated were in like manner raised into the air by some invisible force. Mediums are said to have been raised into the air, and floated about above the heads of the spectators. Writings and pictures were produced without visible hands. Persons were touched by invisible, and sometimes by visible hands. Various musical instruments were played upon without visible agency. Strange feats of legerdemain, as the untying of complicated rope knottings in an incredibly short time, astonished many. Voices were heard, which purported to be those of spirits. In a word, over a vast extent of country, from east to west, these phenomena existed, or were said to exist, in hundreds of places, and were witnessed by many thousands of people—numbers of whom were of the highest credibility, and the mass of those persons whose testimony no one would think of impeaching in a trial of life and death.'

Many theories were invented to explain these phenomena: they are now for the most part obsolete or forgotten. Each theory generally began by exploding its predecessors, and was in turn exploded by its successors. No sooner was a theory invented to explain one class of facts, than another sprang up for which it made no provision, and to which it was manifestly inadequate. Not only did the flame spread, but sometimes the extinguishers caught fire; and those who at first were its opponents, ended as its advocates. The most obdurate materialists became convinced of a future life for man by the experimental evidence spiritualism supplied. For instance, Professor Hare instituted a series of experiments intended to prove that the phenomena were wholly due to natural causes: and the public, and men of science in particular, were surprised when, in place of this explanation, there appeared a large work with his name as its author, entitled *Spiritualism Scientifically Demonstrated;* and with diagrams of ingenious apparatus invented by him to test the genuineness of the phenomena. The Hon. J. W. Edmonds, judge in the Supreme Court of Appeal for the state of New York, brought to bear upon the subject a mind trained by long judicial experience, and the careful sifting of evidence. He investigated with many different mediums, and took notes as carefully as though in court. To his great astonishment he found he was himself a medium, and under the title *Spiritualism*, he published two large volumes, narrating his investigations, visions, and spiritual communications. His daughter, Laura, also became a medium, and under some foreign influence would sometimes answer freely in languages with which in her normal state she was wholly unacquainted.

Reports of these marvels soon crossed the Atlantic; but in England, for a long time, they excited little serious attention, and were generally received, not only with incredulity, but with ridicule and contempt. The visit to London of Mrs. Haydon, an American medium, in 1854, first excited any considerable degree of public interest in spiritualism. Many visited her, most of whom were puzzled, some ridiculed, a few were convinced. Among the latter were Robert Owen, the founder of English Socialism, and Dr. Ashburner, the translator of Reichenbach, and the colleague of Dr. Elliotson in the establishment of the *Zoist* and of the Mesmeric Infirmary. In 1855, a more remarkable medium came to England, Mr. Daniel Dunglas Home. The manifestations which occurred in his presence were soon the subject of newspaper controversy. From that time to this they have been seen and tested repeatedly by scientific and other witnesses of the highest credit and social position; and they made him a frequent and welcome guest at the Tuileries and at the courts of Berlin and St. Petersburg. A full account of his strange experiences is given in his autobiography, entitled *Incidents in My Life.* They include nearly the whole range of 'manifestations' referred to in the important Report of which we are about to speak.

In January 1869, the London Dialectical Society appointed a committee 'to investigate the phenomena alleged to be spiritual manifestations, and to report thereon.' The committee invited evidence from all sides, and especially solicited the co-operation of scientific men, and resolved itself into sub-committees for experimental investigation and test. In July 1871, the committee presented its report, with minutes of evidence, reports of *séances*, and other documents, making a volume of 412 large octavo pages. The committee state that 'a large majority of the members of your committee have become actual witnesses to several phases of the phenomena, without the aid or presence of any professional medium, although the greater part of them commenced their investigations in an avowedly sceptical spirit.'

A synopsis of the evidence is also given as follows: 'Thirteen witnesses state that they have seen heavy bodies—in some instances men—rise slowly in the air, and remain there for some time without visible or tangible support. Fourteen witnesses testify to having seen hands or figures, not appertaining to any human being, but lifelike in appearance and mobility, which they have sometimes touched or even grasped, and which they are therefore convinced were not the result of imposture or illusion. Five witnesses state that they have been touched by some invisible agency on various parts of the body, and often where requested, when the hands of all present was visible. Thirteen witnesses declare that they have heard musical pieces well played upon instruments not manipulated by any ascertainable agency. Five witnesses state that they have seen red-hot coals applied to the hands or heads of several persons without producing pain or scorching; and three witnesses state that they have had the same test applied to themselves with the like immunity. Eight witnesses state that they have received detailed information through rappings, writings, or in other ways, the accuracy of which was unknown at the time to themselves or to any persons present, and which, on subsequent inquiry, was found to be correct. One witness declares

that he has received a precise and detailed statement, which, nevertheless, proved to be entirely erroneous. Three witnesses state that they have been present when drawings, both in pencil and colors, were produced in so short a time, and under such conditions, as to render human agency impossible. Six witnesses declare that they have received information of future events, and that in some cases the hour and minute have been accurately foretold days and even weeks before. In addition to the above, evidence has been given of trance-speaking, of healing, of automatic writing, of the introduction of flowers and fruits into closed rooms, of voices in the air, of visions in crystals and glasses, and of the elongation of the human body.'

One of the latest scientific investigators of spiritualism is Mr. William Crookes, F.R.S., discoverer of the metal thallium, editor of the *Chemical News* and of the *Quarterly Journal of Science*. In the latter journal for January 1874 is an article by him, entitled, 'Notes of an Inquiry into the Phenomena called Spiritual, 1870—1873.' He attests phenomena similar to those affirmed by the Dialectical Society's committee and its witnesses, which came under his notice in his own house, in the light, and with only private friends present except the medium, at times appointed by himself, and under circumstances which, he says, absolutely precluded the employment of the very simplest instrumental aids.

One of the most recent phases of spiritualism in this country is 'spirit photographs.' On clean and previously unused plates, marked by the sitter, and even when the sitter has used his own plates and camera, there has appeared with the sitter a second figure, which in many instances have been recognized as portraits of deceased relatives and friends. In the *Spiritual Magazine* for December 1872, is a list of the names and addresses of forty sitters who have so recognized these figures. They have been obtained by many photographers, both professional and amateur, in England, the United States, and on the continent of Europe.

The *Spiritual Magazine* (the oldest journal of spiritualism in England, and which contains a record of the movement from its establishment in January 1860) has the following as its motto: 'Spiritualism is based on the cardinal fact of spirit communion and influx; it is the effort to discover all truth relating to man's spiritual nature, capacities, relations, duties, welfare, and destiny; and its application to a regenerate life. It recognizes a continuous divine inspiration in man; it aims through a careful, reverent study of facts, at a knowledge of the laws and principles which govern the occult forces of the universe; of the relations of spirit to matter, and of man to God and the spiritual world. It is thus catholic and progressive, leading to true religion as at one with the highest philosophy.'

At a conference in Liverpool in November 1873, at which delegates from about forty societies attended, steps were taken which have led to the establishment of the 'British National Association of Spiritualists'—'to unite spiritualists of every variety of opinion for their mutual aid and benefit; to promote the study of pneumatology and psychology; to aid students and inquirers in their researches, by placing at their disposal the means of systematic investigation into the now recognized facts and phenomena, called spiritual or psychic; to make known the positive results arrived at by careful scientific research; and to direct attention to the beneficial influence which those results are calculated to exercise upon social relationships and individual conduct.'

In 1881 the chief English journals of spiritualism were *Light*, *Medium and Daybreak*, *Spiritualist*, and *Spiritual Notes*, weekly or monthly. In the United States the earliest was the *Banner of Light*, founded in 1857. In 1881 it was stated that there were in Germany 1 spiritualist magazine, in Austria 1, Holland 1, France 1, Belgium 4, England 7, Italy 1, Spain 5, United States 5, Argentine Republic 2, Mexico 2, Colombia 2. The literature of the movement is very voluminous. The following are important works on spiritualism: *Transcendental Physics*, translated from the German of Prof. Zöllner (1880), *Psychic Facts*, by Harrison (1880); *Researches in the Phenomena*, by Crookes (1874); *Modern American Spiritualism*, by Hardinge (1870); *From Matter to Spirit*, by Mrs. De Morgan, with preface by Professor De Morgan; *The Two Worlds*, by Thomas Brevior; *Footfalls on the Boundary of Another World*, and *The Debatable Land*, by Robert Dale Owen; *History of the Supernatural*, by William Howitt; *A Defence of Spiritualism*, by Alfred Russell Wallace; *Lights and Shadows of Spiritualism*, by D. D. Home (1877); *Mesmerism, Spiritualism, &c., Historically and Scientifically Considered*, by W. B. Carpenter, F.R.S. (1877).

SPI'TALFIELDS, a district of London, adjoining Bethnal Green, derives its name from the *hospital* of St. Mary, founded there in 1197, by Walter Brune and his wife Rosia, and is inhabited chiefly by silk-weavers and other poor people. The manufacture of silk was established in S. by emigrants from France, after the revocation of the Edict of Nantes.

SPI'THEAD, a celebrated roadstead on the south coast of England, and a favorite rendezvous of the British navy, is the eastern division—the Solent (q. v.), being the western division—of that strait which separates the Isle of Wight from the mainland. It is protected from all winds, except those from the south-east, and its noted security warranted the name, which has been applied to it by sailors, of the 'king's bedchamber.' It receives its name from the 'Spit,' a sandbank stretching S. from the English shore for 3 miles; and it is 14 miles long by about 4 miles in average breadth. Here, in 1797, the sailors of the Channel Fleet mutinied for more liberal pay and allowances, which were granted to them.

SPI'THEAD FORTS. The troubled state of European politics which gave rise in 1859 to the Volunteer movement, led also to the recommendation of an extensive plan of defence for the arsenals and coast. A Board of Commissioners drew up a scheme for these defences, to cost about £5,000,000, of which a sum of £2,000,000 was for Portsmouth, Spithead, and the neighboring coast. At present, the entrance to the important arsenal and dockyard at Portsmouth is defended by Fort Monckton on the Gosport side, Southsea Castle on the opposite side, Cumberland Fort at the entrance to Langston Harbor, Lumps and Eastney Forts between the two last named, and some defensive lines between the island of Portsea and the mainland. £580.000 was voted in 1860 as a beginning, to increase the number and strength of these forts, to build detached forts on shoals in the sea between the mainland and the Isle of Wight, and to raise fortified lines on Portsdown Hill (the principal work being Fort Southwick), wholly northward of Portsmouth Harbor. The works were commenced; but the often-conflicting lessons furnished by the American war led to much delay and endless variations of plan.

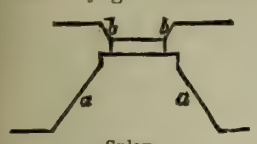
The National Defence Commissioners had proposed five advanced forts on the shoals known as Horse Sand, Noman or No Man's Land Shoal, Sturbridge Shoal, Spit Point, and a point intervening between Horse Sand and Portsea Island. But after much discussion and numerous alterations of plan, it was only in 1864 that it was determined to proceed with the foundations at least of two—the Horse and the Noman forts. The foundation of each fort consists of rings of stone-work, laid on the leveled bed of the shoal, tapering a little upwards from a width of 54 feet to one of 43 feet; the outer diameter of the ring gradually lessening from 231 to 213 feet. From 20 to 15 feet of sub-marine masonry is required. Outside the rings of stone are layers of rubble, to protect the stone-work from the action of tidal rush. Two years later, similar forts were begun on Spit Bank and St. Helens shoal. In 1865 a mortar battery had been erected at Puckpool in the Isle of Wight, commanding at long range the approach to Spithead. In 1868, after it had been found impossible to secure a foundation for a fifth fort on the Sturbridge shoal, Puckpool Battery was strengthened and armed with 30 mortars and four 25-ton guns.

All this time the government had not determined which of three modes to adopt for constructing the forts—whether to form them entirely of iron; or of granite faced with iron; or simply of granite, leaving the facing for after-consideration. The plan most in favor with the government in 1866 was to erect on each of the foundations at Spithead a *revolving* iron fort or tower of enormous magnitude.

Circumstances in 1867 induced the government again to pause. Experiments on the Rodman 15-inch and 20-inch guns led some engineers to believe that no iron casing for forts could resist shot of 500 lbs. to 1100 lbs. from such ordnance; while the rolling of an armor plate 15 inches thick (see ARMOR-PLATES) revived the hopes of those who believe that armor will eventually vanquish guns. Finally, the forts are nearly finished, of a granite core, surrounded by a great thickness of iron plates. Above each fort are revolving turrets carrying 35-ton guns, which throw shells of 700 lbs. The inner line of defence has been strengthened by new works at Gilkicker, Southsea Castle, &c., and by the increase in the size of the guns, and the additon of iron shields in the embrasures.

SPITZBE'RGEN, a group of islands in the Arctic Ocean, in lat 76° 30′—80° 40′ N., and long. 9°—22° E., lies 300 miles north of Scandinavia, and 325 east of Greenland. The group which is estimated to contain about 30,000 Eng. sq. m., is composed of three large and several small islands. The largest of the group, *Spitzbergen Proper*, consists of two oblong and parallel tracts known as West S. and East S. or New Friesland, connected by a neck of land; the whole strongly resembling a boat-hook in shape. The two next in size are *Egede* and *North-east Island*. Being far within the Arctic Circle, and surrounded by a wide expanse of sea, almost the whole of its surface is covered with perpetual snow and glaciers. The whole of the west side is mountainous, the general elevation being 3000—4500 feet above sea-level; and the same is true of the north-east coast. During ten months of the year, mercury freezes, and for the other two months, the temperature is seldom more than 5° above the freezing-point; yet, during this short summer, more than 100 species of plants, which constitute the vegetation of this inhospitable region, succeed in springing up, and producing and ripening

their seed. The whole of S. could not afford sustenance for one human being; but it is, nevertheless, a haunt of reindeer, foxes, and bears, and whales, and seals abound on the coasts. S. has from time to time been occupied by Dutch and Russian colonies, who were supplied from the mainland of Europe. It was discovered, in 1596, by William Barentz, the Dutch explorer, in his third voyage to discover the North-east Passage and has since been frequently visited by other explorers and by whalers. It is claimed as a dependency of its European territories by Russia.



Splay.

SPLAY, the sloping or bevelled opening in window recesses and such openings, as at *a*, *a*. Also the corner taken off the outer angle of such openings, as at *b*, *b*.

SPLEEN, THE, is the largest and most important of the so-called ductless glands, whose chief object is supposed to be to restore to the circulation any substances that may have been withdrawn from it. It is of an oblong flattened form, soft, of very brittle consistence, highly vascular, of a dark bluish-red color, and situated on the left hypochondriac region, with its interior slightly concave surface embracing the cardiac end of the stomach and the tail of the pancreas. (See the figure in the article PANCREAS.) It is invested by an external or serous coat, derived from the peritoneum, and an internal fibrous elastic coat. Mr. Gray, who wrote the Astley-Cooper Prize Essay, *On the Structure and Use of the Spleen*, states that the size and weight of this organ are liable to very extreme variations at different periods of life, in different individuals, and in the same individual under different conditions. In the *adult*, in whom it attains its greatest size, it is usually about five inches in length, three or four in breadth, and an inch or an inch and a half in thickness, and weighs about seven ounces. At *birth*, its weight in proportion to that of the entire body is as 1 to 350, which is nearly the same ratio as in the adult; while in *old age* the organ decreases in weight, the ratio being as 1 to 700. The size of the spleen is increased during and after digestion, and is large in highly fed, and small in starved animals. In intermittent fevers and leucocythemia, it is much enlarged, weighing occasionally from 18 to 20 lbs., and constituting what is popularly known as the *ague-cake*.

On cutting into the spleen, a section of it shows the presence of numerous small fibrous bands termed *trabeculæ*, united at numerous points with one another, and running in all directions. The parenchyma, or proper substance of the spleen, occupies the interspaces of the above described areolar framework, and is a soft pulpy mass of a dark reddish-brown color, consisting of colorless and colored elements. The *colorless elements* are described by Gray as consisting of granular matter, of nuclei about the size of the red-blood discs, and a few nucleated vesicles; and as constituting one-half or two-thirds of the whole substance of the pulp in well-nourished animals, while they diminish in number, and sometimes altogether disappear in starved animals. The *colored elements* consist of red blood-discs and of colored corpuscles either free or included in cells; sometimes enlarged blood-discs are seen included in a cell, but more frequently the enclosed discs are altered in form and color, as if undergoing retrograde metamorphoses. Besides these, numerous deep-red, or reddish-yellow, or black corpuscles and crystals, closely allied to the hæmatin of the blood, are seen diffused through the pulp-substance.

The venos blood of the spleen is carried away by the splenic vein, which contributes to form the great portal venos system, distributed through the liver; while arterial blood is supplied by the splenic artery, the largest branch of the cœliac axis. The branches of this artery subdivide and ramify like the branches of a tree, with the *Malpighian* or *splenic corpuscles* attached to them like fruit. These splenic corpuscles, originally discovered by Malpighi, are whitish spherical bodies, which are either connected with the smaller arterial branches by short pedicles, or are sessile upon their sheaths. They vary considerably in size and number, their diameter usually ranging from one-third to one-sixth of a line. Each consists of a membranous capsule, homogeneous in structure, and formed by a prolongation from the sheath of the artery.

The blood-vessels ramifying on the surface of a corpuscle consist of the larger branches of the artery with which it is connected, of venous branches, and of a delicate capillary plexus. From this arrangement of the vessels, it may be inferred that active changes are carried on in the contents of these corpuscles, which consist of a soft, white, semi-fluid substance, made up of granular matter, nuclei similar to those found in the pulp, and a few nucleated cells. These splenic corpuscles are much more distinct in early life than subsequently, and are much smaller in man than in most mammals. They, however, bear a remarkable relation to the general state of nutrition, being much the greatest in well-fed animals, especially in the early periods of the digestion of albuminous food; while they diminish extremely in ill-fed animals, and in those that have been starved, they disappear altogether.

The chemical composition of the spleen confirms the view that a retrograde change of tissue occurs very freely in it. In 1000 parts, there were found (by Oidtmann) nearly 250 of solid residue, of which more than 243 was organic, consisting of albumen, fats, inosite, uric acid, sarcine, xanthine, leucine, tyrosine, and pigment, all of which, excepting the first two, are products of the metamorphosis of tissue. This gland also contains a large quantity of oxide of iron, obtained probably from the disintegration of red blood-discs in it.

With regard to its uses, it may be regarded as a storehouse of nutritive material, which may be drawn upon according to the requirements of the system; and of the exertion of an assimilative action upon the albuminous matter, during its withdrawal from the general current of the circulation, we have direct evidence in the large increase in the proportion of fibrin contained in its venous blood—the blood of the splenic vein sometimes containing nearly six times the usual quantity of fibrin. Before the institution of the chemical inquiries which led to the above conclusion, it was held that the function of the organ was to act as a reservoir for the portal blood, with the view of preventing the portal vessels from being unduly distended during the digestive process. To what extent it is the seat of the disintegration of old blood-corpuscles, and of the formation of new ones, is still uncertain. The removal of this organ from the body has frequently been performed in animals without serious effects; but in some of these cases, small secondary spleens are developed, and in others, various sets of lymphatic glands are observed to increase rapidly, shortly after the operation, and these probably act vicariously for the spleen. Its singular and complicated microscopic structure, and its extreme vascularity, would lead to the inference that this is a highly important viscus.

It is unnecessary to enter into any detail regarding the diseases of the spleen, as most of them occur secondarily in the course of other affections, as in Intermittent Fever (Ague) and Leucocythemia (q. v.), when it is sometimes enlarged to 40 times its natural weight. It is sometimes diminished to the size of a walnut, the cause of this atrophy being unknown, but the apparent result being a loss of color, and a comparatively bloodless condition. The spleen is also liable to the singular morbid change known as *Waxy Degeneration* in which the presence of starch-like amyloid granules is observed in the tissue on submitting it to microscopico-chemical investigation. These remarkable granules dissolve when heated in water, and by the action of iodine acquire a bluish tint.

SPLEE'NWORT. See ASPLENIUM.

SPLE'NIC APOPLEXY, a disease of cattle and sheep, resembles Black Quarter (q. v.) in suddenly attacking animals in good thriving condition, and, like it, appears to depend upon the rapid manufacture of insufficiently elaborated blood, probably faulty in the healthy proportion of some of its constituents. The animal staggers, froths at mouth, throws itself about in convulsions, and sometimes dies within an hour. Few cases recover. The blood is thin, dark-colored, and indisposed to coagulate. It accumulates in the large internal organs, particularly in the liver and spleen, and is poured out on the mucous surfaces. If the animal is seen in time, and before the pulse becomes small and weak, a moderate bleeding may be tried. A full dose of physic, with a prompt stimulant, must at once be given, and cloths wrung out of hot water applied for several hours continuously, to the belly and loins. If the animal is weak, and the pulse scarcely perceptible, stimulants must be freely given from the first; and where there is stupor, cold water likewise applied to the head. To prevent the disease, attention must be paid to regular moderate feeding; abundance of wholesome water must be supplied; the grazings not allowed to become too rank, and changed occasionally; rock-salt placed within reach; and a seton inserted in the dewlap of animals pastured upon lands subject to S. A.

Pasteur's researches have shown that this fatal disease of splenic fever, also known as Anthrax or Siberian plague, is due to the presence in the blood of small organisms, specific bacteria in the blood. By artificially cultivating these bacteria, he further succeeded in developing a weaker crop of germs. By inoculating healthy animals with the viris, he produced a milder form of the disease, which protects from the more violent and dangerous malady—a process analogous to vaccination. See GERM-THEORY.

SPLINT, or SPLENT, is a bony enlargement on the horse's leg, between the knee and fetlock, usually appearing on the inside of one or both forelegs, frequently situated between the large and small canon bones, depending upon concussion, and most common in young horses that have been rattled rapidly along hard roads before their bones are consolidated. When of recent and rapid growth, the splint is hot and tender, and causes lameness, especially noticeable when the horse is trotted along a hard road. A piece of spongiopiline saturated with cold water should be ap-

plied to the splint, kept in position with a light linen bandage, and wetted with cold water or a refrigerant mixture every hour. Perfect rest must be enjoined for ten days or a fortnight. When the limb is cool, and free from tenderness, the swelling, which will still remain, may be greatly reduced by some stimulating applications, such as the ointment of the red iodide of mercury, the common fly-blister, or the firing-iron.

SPLINT-BONES. The horse and certain allied mammals have what is popularly known as an outer and an inner splint-bone in the skeleton of the leg. Beyond the bones of the carpus and tarsus, there is one very large bone (the metacarpal or metatarsal of the third toe), which supports the whole weight of the animal. On either side of this bone are the outer and inner splint-bones, which are small bones, not running more than half the length of the great central bone, into which they merge. They represent, in a rudimentary form, the metacarpal and metatarsal bones of the fourth and second toe.

SPLINTS, in Surgery, are certain mechanical contrivances for keeping a fractured limb in its proper position, and for preventing any motion of the fractured ends; they are also employed for securing perfect immobility of the parts to which they are applied in other cases, as in diseased joints, after resection of joints, &c.

Ordinary splints are composed of wood carved to the shape of the limb, and padded; the best pads being made out of old blankets, which should be cut into strips long and wide enough to line the splints, and laid in sufficient number upon one another to give the requisite softness. The splints should be firmly bound to the previously bandaged limb with pieces of bandage, or with straps and buckles; care being taken that they are put on sufficiently tight to keep the parts immovable, and to prevent muscular spasm, but not so tight as to induce discomfort. Gutta percha, sole-leather, or pasteboard, after having been softened in boiling water, may in some cases advantageously take the place of wooden splints. They must be applied when soft to the part they are intended to support, so as to take a perfect mould, and then be dried, stiffened, and, if necessary, lined. An account of the more complicated kinds of splint required in certain cases, as Macintyre's Splint, Liston's Splint, &c., may be seen in any illustrated catalogue of surgical instruments.

The ordinary splint is now to a great degree superseded by immovable bandages, which consist of the ordinary bandage saturated with a thick mucilage of starch, or with a strong solution of a mixture of powdered gum-arabic and precipitated chalk, which, when dry, form a remarkably light but firm support. As, however, these bandages require some hours to dry and become rigid, means must be used to counteract any displacement of the limb in the interval. On this account, many surgeons prefer the plaster of Paris or gypsum bandage, which is applied in the following manner: the limb being protected by a layer of cotton-wool, a bandage composed of coarse and open material, into which as much dry powdered gypsum as possible has been rubbed, must be immersed in water for about a minute, and then rolled around the limb in a spiral manner, just as an ordinary bandage; after every second or third turn of the bandage, the left hand of the surgeon should be plunged into water, and smeared over the part last applied. When the whole has been thus treated, the exterior of the bandage should be smeared over with a paste of gypsum and water until a smooth surface and complete rigidity have been attained—a process not occupying more than ten minutes or a quarter of an hour.

In a case of simple fracture, where no surgical aid is at hand, any non-professional person of ordinary intelligence might apply this bandage, extreme care being taken that the ends of the broken bones are in their proper position.

SPLÜ'GEN, a mountain of the Lepontine Alps, in the Grisons, Switzerland, whose summit, 9600 feet high, bears the name of the Tombenhorn. The pass of the Splügen, connecting the south-east of Switzerland with the region of Italy round Lake Como, is at its highest point 6940 feet above the sea, and in its present condition is the work of the Austrian government (1823.) The southern or Italian descent has three great 'galleries'—i. e., covered portions of the pass constructed of solid masonry, and intended to protect the road from avalanches. They are the longest on any Alpine high-road. When Marshal Macdonald conducted the French army of reserve across the S. by the old path, 27th November—4th December 1800, he lost severely in men and horses from the fall of avalanches

SPOHR, LUDWIG, an eminent German musical composer and violinist, son of a physician of Brunswick, and born in that town in 1784. He began his violin studies in boyhood; at the age of twelve, he played a violin concerto of his own at the court of Brunswick; and at thirteen he obtained an appointment as chamber-musician to the duke. A few years later he made a musical tour through Russia and Germany, giving concerts, and acquiring a high reputation as a performer on the violin. In 1804, he became music director at the court of Saxe-Gotha, and held afterwards for several years the office of Music Director of the Theater an der Wien at Vienna. He visited Italy in 1817, Paris in 1819, and in 1820 appeared in London, where he was received with great applause at the Philharmonic Society's concerts, and produced two symphonies and an overture. In 1823, he became Kapellmeister at the court of Hesse-Cassel, which post he continued to hold till 1857, when he retired from professional life. He died in 1859.

S.'s musical works include seven operas—*Faust*, *Jessonda*, *Zemira und Azor*, *Der Zweikampf der Geliebten*, *Der Berggeist*, *Peter von Albano*, and *Der Alchymist;* three oratorios, *Die letzten Dinge*, *Des Heiland's letzte Stunden*, and *Der Fall Babylons;* various masses, psalms, and hymns, six grand symphonies, four overtures, besides nonettes, quartetts, violin concertos, sonatas for violin and harp, fantasias, and rondos. *Die letzten Dinge*, or Last Judgment, is a very grand and very attractive work; so also is *Der Fall Babylons*, first produced at a Norwich musical festival. Of his operas, the most esteemed are *Faust* and *Jessonda*, the latter remarkable for its successful embodiment of the spirit of oriental poetry. His songs are rather deficient in broad and decided melody; but his instrumental works occupy a very high place in the estimation of musicians, more especially the C minor symphony, and the symphony known as *Die Weihe der Töne*. As a violinist, S.'s purity of tone and high finish have never been surpassed, and his *Violinschule* is the best and most complete work on violin-playing ever written.—See *The Autobiography of L. Spohr;* translated from the German (Lond. 1864).

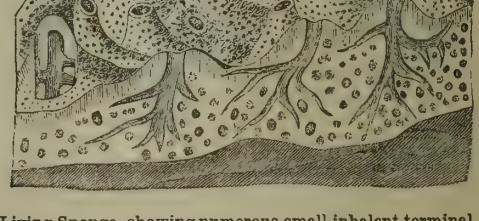
SPOLE'TO (Latin, *Spoletium*), a city of Central Italy, province of Perugia, is situated on a rocky hill, 61 miles north-north-east of Rome. Pop. (1871) 7493. It is commanded by a citadel, which is built on a separate hill, divided from that on which the town stands by a deep gorge, crossed at an immense height by a bridge and aqueduct. The streets are steep, narrow, and dirty. S. has a fine cathedral, built in the time of the Lombard dukes, and containing many interesting works of art. The churches of St. Dominico, San Giovanni, the collegiate church of San Pietro, and the palace of the ancient dukes of S., are also worthy of being mentioned.

The ancient *Spoletium* had its origin in a Roman colony which was planted here about 240 B.C.; and during the second Punic War, Hannibal is said to have been repulsed by the colonists in an assault which he made on the town (217 B.C.), after the battle of Thrasymene. Under the Lombard dukes, it became the capital of an independent duchy. In 1860, it was taken by the Italians from a body of Irish mercenaries in the service of the pope, and now forms a part of the Kingdom of Italy. S. contains many interesting Roman remains, as also a ruin which goes under the name of the Palace of Theodoric. It has manufactures of woollens and hats.

SPO'NDIAS. See HOG PLUM.

SPONGE (*Spongia*), a genus which originally included all the numerous genera and species of the family *Spongiadæ*, all of which are still commonly spoken of by naturalists as sponges, although in its more popular sense that term is limited to a few kinds, or to their fibrous framework. The sponges are creatures of very low organization, concerning which controversies long raged, first as to whether they ought to be referred to the animal or the vegetable kingdom, and more recently as to their systematic position in the former group. At first referred to the *Protozoa*, and later to the *Cœlenterata* (see ZOOLOGY), they are now considered by the greater number of naturalists as entitled to rank as a separate subkingdom, *Porifera*, characterized by the multitude of mouths or inhalent apertures which open through the body wall, the primitive mouth of the two-layered sac-like embryo being converted into the large exhalent opening.

They may be classified as follows: 1. *Myxospongiæ* destitute of



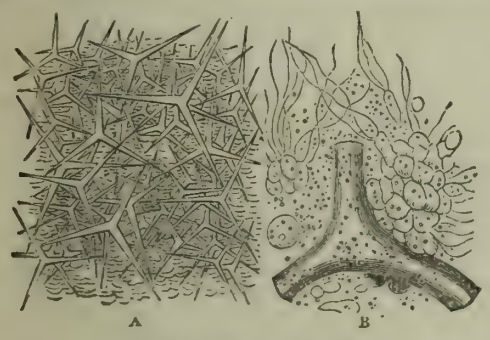
Living Sponge, showing numerous small inhalent terminal, large exhalent orifices.

skeleton; 2. *Fibro-spongiæ*, having a fibrous skeleton, with or without siliceous spicules; 3. *Calcispongiæ*, having calcareous spicules. These spicules are not purely mineral, but contain a trace of organic matter. They are most beautiful microscopic objects,

and spicules of different forms are sometimes found in the same species, sometimes lying close together in bundles, sometimes straight or slightly curved, sometimes in the shape of needles pointed at one end, or at both; sometimes of needles radiating from a center; whilst some have a head at one end, like a pin, some have grapnel-like hooks at the ends. Some of the species with horny framework have spicules imbedded in it; some have them implanted in the fibres; some are destitute of them. There is a beautiful West Indian species, *Dictyocalyx pumiceus*, in which the siliceous matter becomes itself a fibrous network, and is so fine and transparent as to resemble spun glass. In a living state, many sponges exhibit lively colors, from the presence of coloring matter.

Like any of the higher animals, the body of the sponge is composed of a distinct outer layer of cells, the ectoderm or epidermis, and a ciliated inner layer or endoderm (often restricted to definite areas, the so-called 'ciliated chambers'), between which a middle layer of cells, the mesoderm arises. This may be of very variable thickness, and gives rise to the skeleton. From the close resemblance which the cells of the ectoderm and mesoderm present to *Amœbæ*, and those of the endoderm to those Infusorians known as *Monads*, it has been argued that the sponge is a mere colony of Protozoa. The development of the sponge, however, accords too closely with that of higher animals to admit of such a view, a free-swimming ciliated larva being produced by segmentation of a fertilized ovum; but it is undeniable that in the sponge we have a degree of independence of the cell units far greater than that which exists in any other group—a divided sponge readily reunites, and adjacent masses grow together. They assume very various forms, which, as well as the peculiarities in the structure of the framework, are characteristic of the different genera and species. Some are nearly globular; some cup-shaped, top-shaped, conical, cylindrical, thread-like, &c.; some are simple, and some branched.

The surface of a living sponge is generally covered with minute pores, through which water is imbibed, carrying with it both the air and the organic particles necessary for the support of life. The pores are supposed to be permanent in many of the sponges,



Structure of *Grantia compressa*:
A, portion showing general arrangement of triradiate spicules and intervening tissue, magnified; B, small portion highly magnified, showing ciliated cells.—From Carpenter *On the Microscope*.

and the currents which enter through them to be produced by cilia, although these have as yet been detected only in a few species. But in those of the very lowest organization, the pores seem to be formed for the occasion, just as the *Amœba* opens anywhere to admit food within its substance.

In *Spongilla fluviatilis*, a small fresh-water species found in Britain, the opening and closing of each pore occupies less than a minute, and the pores do not open simultaneously, but in irregular succession, and apparently never again in precisely the same spot. No trace of the pore remains for an instant after its closing, nor is there any indication of the point where a new one is to open. The water which enters by the pores passes out of some sponges by a single orifice, which serves for the whole mass; others have numerous orifices (*oscula*) which are permanent, and are much larger than the pores by which the water is imbibed, the whole mass being pervaded by canals which lead from the pores to these orifices, from which, under the microscope, a constant discharge of water may be seen taking place, minute opaque particles being carried along with its current. These particles are not only fæcal matter, but gemmules and ova.

Reproduction takes place both by gemmation and by true ova. Many of the gemmules go to increase the sponge-mass; but the greater part finally become detached, and are carried out into the water, to settle down in a new locality. Mr. Huxley has detected true ova and sperm-cells imbedded in the substance of sponges.

The sponges employed for domestic and other purposes derive their value from the elasticity and compressibility of their fibrous framework, divested of the glairy substance, and its power of imbibing fluids. The absence of spicules is essential to a useful sponge. The kinds fit for use are found in the seas of warm climates. Some small species of sponge live at great depths. One has been brought up in the Gulf of Macri from a depth of 185 fathoms. Numerous species of sponge are very abundant on many parts of the British coasts.

Fossil remains of sponges are found in many rocks, and of horny, fibrous kinds, as well as of those with calcareous or siliceous framework.

Several species of sponge are in use for economical purposes. Two species are chiefly brought from the Levant, and a very inferior one from the West Indies and coast of Florida. The trade in sponge is very considerable; it is carried on chiefly by the Turks and the inhabitants of the Bahama Islands. The number of men employed in the Ottoman sponge-fishery is between 4000 and 5000, forming the crews of about 600 boats. These boats find their chief employment on the coasts of Candia, Barbary, and Syria. The sponge is obtained by diving, the diver taking down with him a flat piece of stone of a triangular shape, with a hole drilled through one of its corners; to this a cord from the boat is attached, and the diver makes it serve to guide him to particular spots. When he reaches the growing sponges, he tears them off the rocks, and places them under his arms; he then pulls at the rope, which gives the signal to his companions in the boat to haul him up. The value of sponges collected in Greece and Turkey is from £90,000 to £100,000 annually. The Greeks of the Morea, instead of diving, obtain sponges by a pronged instrument; but the sponges thus collected are torn, and sell at a low price. The best sponges are obtained on detached heads of rock in 8 or 10 fathoms water.

The sponges of the Bahamas and other West Indian islands are of a larger size and coarser quality; but large quantities are gathered; and about 215,000 lbs., worth £17,000, are sent annually to Great Britain. The sponges are torn from the rocks by a fork at the end of a long pole. To get rid of the animal matter, they are buried for some days in the sand, and then soaked and washed.

The domestic uses of sponge are familiar to every one. It is also of great value to the surgeon, not only for removing blood in operations, but for checking hæmorrhage. Burnt sponge was once a valued remedy was scrofulous diseases and goitre; but iodine and bromine, from which it derives all its value, are now administered in other forms.

SPO'NSOR (Lat. one who promises), the name given in theological use to a Godfather[s] or Godmother (q. v.). The name is derived from the circumstance, that in baptism or confirmation, and especially in infant baptism, the sponsor is understood to make certain promises or engagements in the name, and on the part of the person baptized or confirmed. The idea of sponsorship is entirely rejected not only by Baptists, but generally also by Presbyterians and Independents.

SPONTANE'ITY, the name for the doctrine, referring to the Human Mind, that muscular action may, and does, arise from purely internal causes, and independent of the stimulus of sensations. It had long been the tacit assumption, in Mental Philosophy, that we are never moved to action of any kind, except under the stimulation of some feeling, some pleasure or pain, or some end in view. To this is now opposed the doctrine of the Spontaneous commencement of movements under certain circumstances; which, however, does not exclude, but only supplements, the operation of the feelings in stimulating movements, as in the ordinary course of voluntary action. The doctrine supposes that the nerve-centers, after repose and nourishment, acquire a fulness of vital energy, which discharges itself in the play of movement, without any other occasion or motive; the addition of a feeling, or end, enhances and directs the activity, but does not wholly create it.

Of the various proofs and illustrations of Spontaneity, perhaps the most striking is that furnished by the movements of young animals of the active species. A young dog or kitten shows a degree of activity out of all proportion to any feeling to be gratified, or any end to be served; we can interpret it only as internal energy seeking vent, irrespective of the pursuit of pleasure or the avoidance of pain—in other words, the action of the will. When the accumulated energy is expended, the animal falls back into a state of repose, and is then roused only by the stimulus of sensation. The state called 'freshness' in a horse, for example, is a state of superabundant and irrepressible activity. Children go through the same phase: after rest or confinement, they burst forth incontinently into some form of active excitement, of which a part may be considered as pure spontaneity, while part may be owing to sensation.

The doctrine is well fitted to express the difference between the active and the sensitive temperaments; for if it were true that action is in proportion to the stimulation of the feelings, the most susceptible characters would be the most active. But, in point

of fact the active temperament is manifested by a profusion of activity for its own sake, with little circumspection or regard to consequences; and constitutes the restless, bustling, roughshod, energetic, and enterprising disposition of mind, as seen in sportsmen soldiers, travelers, &c.

The explanation of the growth of the Will (q. v.), or voluntary power, involves the spontaneous beginning of movements.—See Bain on *The Senses and the Intellect*, 2d edit., p. 76.

SPONTA'NEOUS COMBU'STION is a phenomenon that occasionally manifests itself in mineral and organic substances. The facts connected with the spontaneous ignition of *mineral* substances are well known to chemists, and some of them have been already described in the article PYROPHORUS (q. v.). Ordinary charcoal does not undergo combustion in air under a temperature of 1000°, but in some states it is liable spontaneously to acquire a temperature which may lead to unexpected combustion. Thus, lamp-black impregnated with oils, which contain a large proportion of hydrogen, gradually becomes warm, and inflames spontaneously. According to M. Aubert, Chevallier, and other French observers, recently-made charcoal, in a state of fine division, is liable to be spontaneously ignited without the agency of oil; but we are not aware that this phenomenon has been observed in this country. There have been many instances of the spontaneous ignition of coals containing iron pyrites, (q. v.) when moistened with water. The pyrites which most readily give rise to spontaneous combustion are those in which the protosulphide is associated with the bisulphide of iron; and these occur in the Yorkshire coals from Hull, and in some kinds of South Wales coal. Sulphur has no tendency to spontaneous combustion, but Dr. Taylor refers to an instance that came to his own knowledge, in which there was reason to believe that the vapor of bisulphide of carbon in an india-rubber factory was ignited by solar heat traversing glass. Phosphorus, when in a dry state, has a great tendency to ignite spontaneously, and it has been observed to melt and take fire (when touched) in a room in which the temperature was under 70°. The ordinary lucifer-match composition is luminous in the dark, in warm summer nights, which shows that oxidation, and therefore a process of heating, is going on. Hence, large quantities of these matches kept in contact may produce a heat sufficient for their ignition. 'I have seen them ignite,' says Dr. Taylor, 'as a result of exposure to the sun's rays for the purpose of drying.'—*Principles and Practice of Medical Jurisprudence*, 1865, p. 603.

From these cases occurring in the mineral kingdom, we pass to the consideration of spontaneous combustion in *organic* substances. Passing over the accidents that may result from the admixture of strong nitric or sulphuric acid with wool, straw, or certain essential oils, and which, if they occur, are immediate and obvious, we have to consider the cases in which, 'without contact with any energetical chemical compounds, certain substances—such as hay, cotton and woody fibre generally, including tow, flax, hemp, jute, rags, leaves, spent tan, cocoa-nut fibre, straw in manure-heaps, &c.—when stacked in large quantities in a damp state, undergo a process of heating from simple oxidation (eremacausis) or fermentation, and, after a time, may pass into a state of spontaneous combustion.'—Taylor, *op. cit.* p. 606. There is undoubted evidence that hay and cotton in a damp state will occasionally take fire without any external source of ignition. Cotton impregnated with oil, when collected in large quantity, is especially liable to ignite spontaneously; and the accumulation of cotton-waste, used in wiping lamps and the oiled surfaces of machinery, has more than once given rise to accidents, and led to unfounded charges of incendiarism. Dr. Taylor relates a case in which a fire took place in a shop 'by reason of a quantity of oil having been spilled on dry sawdust.' According to Chevallier, vegetables boiled in oil furnish a residue which is liable to spontaneous ignition; and the same chemist observes that all kinds of woollen articles imbued with oil, and collected in a heap, and hemp, tow, and flax, when similarly treated, may ignite spontaneously.

In the case of Hepburn *v.* Lordan, which came before Vice-chancellor Wood in January 1865, and was carried by appeal before the Lords Justices, in the following month, an attempt was made to prove that wet jute was liable to undergo spontaneous combustion; and the great fire at London Bridge in 1861 was referred to the spontaneous combustion of jute in its ordinary state. With regard to the latter hypothesis, Dr. Taylor remarks that it is wholly incredible, and from experiments which he made for the defendants in the above lawsuit, and on other grounds, he holds that there is no evidence of moist jute undergoing spontaneous combustion; but, he adds, although no cases are recorded, it is probable that jute, cocoa-nut fibre, and linen and cotton rags, imbued with oil, might undergo this change. Dry wood is supposed by Chevallier and some other chemists to have the property of igniting spontaneously. Deal which has been dried by contact or contiguity with flues or pipes conveying hot water or steam at 212°, is supposed to be in a condition for bursting into flame when air gets access to it; and the destruction of the Houses of Parliament, and many other great fires, have been ascribed to this cause; but from the experiments of Dr. Taylor (*op. cit.*, p. 615) this view must be regarded as untenable.

It is still an open question whether such organic nitrogenous matters as damp grain or seeds of any kind ever undergo spontaneous combustion. In a case recorded in the *Annales d'Hygiène* for 1841, MM. Chevallier, Ollivier, and Devergie drew the conclusion that a barn had caught fire from the spontaneous combustion of damp oats which were stored in it. No such cases are known to have occurred in this country.

The subject of the article is of extreme importance, not only because it may cause great destruction of life and property, but because it may lead to unjust charges of incendiarism.—For further details regarding it, the reader is referred to Graham's 'Report on the Cause of the Fire in the *Amazon*,' in the *Quarterly Journal of the Chemical Society*, vol. v. p. 34; to the article 'Combustion' in Watts's *Dictionary of Chemistry*, vol. i.; and to the elaborate chapter on this subject in Taylor's *Principles and Practice of Medical Jurisprudence*.

SPONTANEOUS COMBUSTION OF THE HUMAN BODY. In medico-legal works, cases are recorded, generally of a somewhat ancient date, in which it was supposed that the body was either spontaneously consumed by inward combustion, or acquired such extraordinary combustible properties as to be consumed when brought into contact with fire. The following is one of the first of the cases on record. It rests on the authority of Le Cat, a distinguished surgeon of his time, and is stated to have occurred at Rheims in 1725. The remains of a woman named Millet were found burned in her kitchen, about eighteen inches from the open fire-place. Nothing was left of the body, except some parts of the head, of the legs, and of the vertebræ. Suspicion was excited against the husband, and a criminal inquiry was instituted; but learned experts reported that the case was one of spontaneous combustion, and the prisoner was acquitted. The facts are explicable on the supposition, that the clothes of the deceased woman were accidentally ignited; and although the almost complete destruction of the body appeared to the medical men of that time to be inconsistent with the ordinary effects of fire, subsequent observations have shown that this is an error. In reference to this case, Liebig observes that it is easy to see that the idea of spontaneous combustion arose at a time when men entertained entirely false views on the subject of combustion, its essence, and its cause. What takes place in combustion generally has only been known since the time of Lavosier (about a century ago), and the conditions which must be combined in order that a body should continue to burn, have only been known since the time of Davy, or for little more than half a century. From the time when the case of Millet occurred to the present day, probably somewhat over 50 supposed cases have been recorded. (In an article published on the subject by Dr. Frank of Berlin in 1843, 45 cases are adduced.)

From an analysis of all the cases on record up to 1851, Liebig arrives at the conclusion that the great majority agree in the following points: '1. They took place in winter. 2. The victims were brandy-drinkers in a state of intoxication. 3. they happened where the rooms are heated by fires in open fireplaces and by pans of glowing charcoal, in England, France, and Italy. In Germany and Russia, where rooms are heated by means of closed stoves, cases of death ascribed to spontaneous combustion are exceedingly rare. 4. It is admitted that no one has ever been present during the combustion. 5. None of the physicians who collected the cases, or attempted to explain them, has ever observed the process, or ascertained what preceded the combustion. 6. It is also unknown how much time had elapsed from the commencement of the combustion to the moment when the consumed body was found.'—*Letters on Chemistry*, 3d ed., 1851, p. 282. Out of the 45 cases collected by Frank, there are only three in regard to which it is assumed that combustion took place when no fire was in the neighborhood; and Liebig distinctly shows that these three solitary cases are totally unworthy of belief. With regard to the other cases, the writers who record them do not deny the presence of fire, but assume that the body was ignited by the fire, and then burned on like a candle or a bundle of straw, under similar conditions, till nothing but ashes or charcoal was left. These writers maintain that excess of fat, and the presence of brandy in the body, induce an abnormal condition of easy combustibility; but Liebig shows, by numerous illustrations, the utter fallacy of this view; and adds, as further evidence, 'the fact that hundreds of fat, well-fed brandy-drinkers do not burn, when by accident or design they come too near a fire. It may with certainty be predicted, that so long as the circulation continues, their bodies would not take fire, even if they held a hand in the fire till it was charred.' Spontaneous combustion in a living body is (he adds) absolutely impossible.

Notwithstanding the wide promulgation of Liebig's views, the

belief in the possible occurrence of spontaneous combustion, seems not yet to have disappeared. In 1847, the body of a man, aged 71, and who was neither fat nor a drunkard, was found in bed in a state of combustion. Dr. Nasson, who was commissioned to investigate the case, reported that the burning must have resulted from some inherent cause in the person—probably roused into activity by a hot brick that was placed at his feet; and Orfila is reported to have coincided in this opinion.' This case is reported in the *Gazette Médicale*, September 4, 1847. On the 13th of June 1847, the Countess of Goerlitz was found dead in her bedroom, with the upper part of her body partly consumed by fire. The head was a nearly shapeless black mass, with the charred tongue protruding from it. The physician who was consulted could suggest no other explanation than that the body of the countess must have taken fire spontaneously, and not even by ignition of her dress by a candle. On this evidence, she was buried; but circumstances having led to the suspicion that she had been murdered by her valet Stauff (who had been detected in attempting to poison the count), her body was exhumed in August 1848, fourteen months after her death, and was subjected to a special examination by the Hesse Medical College, who reported that she had not died from spontaneous combustion. The case was then referred to Liebig and Bischoff, and their report was issued in March 1850, when Stauff was put upon his trial. They found no difficulty in concluding that the body was wilfully burned *after death*, for the purpose of concealing the murder (either by strangulation or a blow on the head), which had been previously perpetrated. The prisoner was convicted, and subsequently confessed that he had committed the murder by strangulation, as indeed the protruded tongue might have suggested. Since that date, there has not been any case of alleged spontaneous combustion.—On this subject, the reader is referred to the various articles on 'Spontaneous Combustion' in the Medical Dictionaries and Encyclopædias; to Dupuytren's *Leçons Orales;* to Liebig's *Letters on Chemistry;* and to Taylor's *Medical Jurisprudence.*

SPONTANEOUS GENERATION. See GENERATION SPONTANEOUS.

SPONTOO'N, a weapon bearing resemblance to a halberd, which, prior to 1787, was borne instead of a half-pike by officers of British infantry. It was a medium for signaling orders to the regiment. The spontoon planted in the ground commanded a halt; pointed backwards or forwards, advance or retreat; and so on.

SPOOL, in Spinning, a wooden reel for winding yarn upon. In sewing and lace-making machines, the spools are of metal, and their forms vary according to the requirements of the machine.

SPOO'NBILL (*Platalea*), a genus of birds of the Heron family (*Ardeidæ*), much resembling storks both in their structure and their habits, but distinguished by the remarkable form of the bill, which is long, flat, broad throughout its whole length, and much dilated in a spoon-like form at the tip. The species are not numerous, but are widely distributed. The only European species is the WHITE S. (*P. leucorodia*), rare in Britain, although in former times, before the draining of the fens in England, it was a more frequent summer visitor. It is common in Holland, in marshy districts throughout the northern parts of Europe and Asia in summer, and in the salt marshes of the coast of Italy in winter. It also inhabits Africa, and its range extends over the whole of that continent. It is gregarious, and the flocks of spoonbills generally make their nests in woods, in the tops of lofty trees. It is considerably smaller than the Common Heron. Its color is white, slightly tinged with pink; the bill and legs are black. A curious convolution of the windpipe, in the form of the figure 8, is found on dissection in the adult S., but does not exist in the young. The flesh of the S. is said to be tender and of good flavor. The S. is easily tamed, is quiet and inoffensive, and feeds readily on any offal.—The ROSEATE S. (*P. ajaja*) is an American species; very abundant within the tropics, and found in the most southern parts of the United States. It is nearly equal in size to the White S., which it resembles in its habits, It is a beautiful bird, with plumage of a fine rose-color, of which the tint is deepest on the wings; the tail-coverts crimson.

SPO'RADES. See ARCHIPELAGO.

SPORA'DIC (Gr. scattered) is a term applied to any disease that is naturally epidemic or contagious, when it attacks only a few persons in a district, and does not spread in its ordinary manner. The conditions on which the occurrence of epidemic or contagious diseases in a sporadic form depend are unknown. Amongst the diseases which occur in this form may be especially mentioned catarrh, cholera, dysentery, measles, scarlatina, and small-pox.

SPORE, in Botany, may be called the *seed* of a cryptogamous plant, as it serves the same purpose of reproduction as the seed of a phanerogamous or flowering plant, and after remaining for a time in a state of rest, is developed into a new plant on the occurrence of the necessary conditions. A spore, however, differs very much from the seed of a phanerogamous plant, as it always consists of a single cell, and therefore does not contain any *embryo* or rudiment of the future plant. In its formation, it corresponds rather with the grains of pollen in the anther of a flower. Spores are small, often so minute as to be invisible to the naked eye—many of them extremely minute, so that they may be wafted about unperceived. This, indeed, might be expected from the very small size of many of the cryptogamic plants themselves, as moulds and many other fungi. But even the spores of the largest ferns are very small. Spores often remain capable of germination for many years, and they seem to be capable of enduring much drought without destruction. They seem to germinate indifferently from any part of their surface, in which they differ essentially from the seeds of phanerogamous plants. In the parent plant, they are either scattered singly, or are united in a fruit-like envelope, which is generally known as a *Sporangium*, or *Sporecase*. In some plants, they are united in definite numbers, as of four (a *tetraspore*), surrounded by an envelope (*perispore*, or *sporidium*). The peculiar reproductive organ, which in some cryptogamous plants produces the spores, is called a *sporocarp*, or a *sporophore*. In many plants, as in mushrooms, the production of spores belongs exclusively to a part of the plant called the *hymenium*.

SPORTS, BOOK OF, the name popularly given to a Declaration issued by James I. of England in 1618, to signify his pleasure that on Sundays, after divine service, 'no lawful recreation should be barred to his good people, which should not tend to the breach of the laws of his kingdom and the canons of his church.' The sports specified were dancing, archery, leaping, vaulting, May-games, Whitsun-ales, morrice-dances, and the setting up of May-poles. The occasion of this proclamation was the conduct of some Puritan authorities in Lancashire, who, in illegally suppressing, instead of regulating, the customary recreations of the common people, had excited much discontent, and increased the influence of the Roman Catholics by giving a repulsive aspect to the Reformed religion. Although the Declaration was ordered to be read in the parish churches of the diocese of Chester, this order was not enforced, and the king's design was allowed to drop. Among the excepted unlawful sports were bear-baiting, bull-baiting, bowling, and interludes. Non-conformists and others not attending divine service at church were prohibited from joining in the sports, nor was any one allowed to go out of his own parish for that purpose, or to carry offensive weapons. By republishing this Declaration in 1633, and enforcing with great severity the reading of it by the clergy in their churches (see SABBATH), Charles I. and Laud excited among the Puritans a degree of indignation which contributed not a little to the downfall of the monarchy and the church. In 1644, the Long Parliament ordered all copies of it to be called in and publicy burned.—Heylin's *Hist. of the Sabbath and Life of Laud*, Fuller's *Church History*, D'Israeli's *Life of James I.*, Southey's *Book of the Church*, Hallam's *Constitutional History of England*, and Cox's *Literature of the Sabbath Question.*

SPOTTISWOOD, JOHN, Archbishop of St. Andrews, son of John Spottiswood, Superintendent of Lothian, was born in the year 1565. He was educated at the university of Glasgow, and on his father's death, succeeded him as Parson of Calder. In 1601, he attended the Duke of Lennox as chaplain, when that nobleman was sent as ambassador to France by King James VI. When James succeeded to the English crown, S. accompanied him on his journey to London, and, soon after that event, on the death of Archbishop James Beaton, was appointed to the see of Glasgow. He was chosen Moderator of the General Assembly of the Scottish Church, which met at Glasgow in 1610, and completed the establishment of episcopal government, which James had labored so long to accomplish. In October of that year, he was, along with the bishops of Brechin and Galloway, consecrated at London House by the Bishop of London and other English prelates. In 1615, he took a leading part in the examination of John Ogilvie, a Jesuit priest, who was apprehended at Glasgow, and hanged for refusing to disown the temporal power of the pope. The share he took in this matter was most discreditable to the archbishop. In the course of the same year, he was translated to the see of St. Andrews. As primate of the Scottish Church, S. had now the chief management of ecclesiastical affairs, and great influence also in the civil government, and his rule was marked by uniform ability, and, with rare exceptions, by prudence and moderation. He presided at the Assembly which met at Perth in 1618, and sanctioned the five points of ecclesiastical discipline known as the Perth Articles. He was as much in favor with King Charles I. as he had been with King James, and at the coronation of that sovereign at Holyrood in 1633, he placed the crown on his head and anointed him.

In 1635, S. was made Chancellor of Scotland, a dignity which no churchman had held since the Reformation; but in accepting

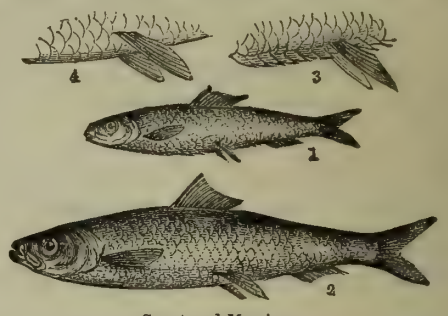
an appointment so invidious to the nobles, he did not act with his usual discretion. He reluctantly entered into the king's unwise measures for the introduction of a liturgy into Scotland, and became one of the chief objects of popular dislike when the Covenanters acquired the ascendency. He soon found it necessary for his safety to retire to England, and in the end of 1638, at the king's request he resigned the chancellorship. He protested against the lawfulness of the General Assembly which met at Glasgow in November of the same year, and was deposed and excommunicated by that body for alleged offences, which, so far as his private character was concerned, were improbable in themselves, and supported by no evidence whatever. The archbishop did not long survive the overthrow of the polity which it had been the work of his life to build up. He died at London on the 26th of November 1639, being then in the 74th year of his age. He had expressed a wish to be buried at Dairsie in Fife, where he had rebuilt the church after the English model, but this was found impracticable, and he was interred in Westminster Abbey. The writings of S. are his well-known *History of the Church of Scotland*, first published in 1655; a Sermon preached at the meeting of the Perth Assembly of 1618, which was published by Bishop Lindsay in 1621 in his account of the proceedings of that Assembly; and a Latin treatise, *Refutatio Libelli de Regimine Ecclesiæ Scoticanæ*, written in answer to a tract of Calderwood's, and published in 1620. The chief authorities for the biography of the archbishop are the Life ascribed to Bishop Duppa, prefixed to the folio editions of his *History*, and the Life by Bishop Russell, prefixed to the Spottiswood Society edition of the same work.

SPRAIN. A sprain or *strain* is a term employed in Surgery to designate a violent stretching of tendinous or ligamentous parts with or without rupture of some of their fibres. Sprains are very frequent in all the joints of the upper limbs, especially in the wrist and the articulations of the thumb. In the lower extremity the ankle is the joint by far the most frequently affected; and this is accounted for anatomically by the small size of the articular surfaces, the great weight the astragalus (the bone presenting the lower articular surface) has to support, and the unyielding nature of the lateral ligaments. In slight sprains of this joint, the ligaments are only stretched or slightly lacerated, but in more severe cases they may be completely torn through. Sprains of the ankle are sometimes mistaken for fractures and *vice versâ;* and the two injuries may co-exist. The pain and swelling sometimes make an accurate diagnosis difficult, especially if the patient is not seen for some time after the accident; and if any doubt exists, the case should be treated as for the more severe injury, since it is better that the treatment should be prolonged than that the patient should be maimed; and fortunately, that which is the proper treatment of a fracture is the best that can be employed for a sprain. Sprains of the knee are not uncommon, and are characterized by great swelling from effusion of fluid within the joint.

Sprains of the back are not unfrequent accidents, and are the most serious of any, but in most cases it may be anticipated that after confinement in bed or on a sofa for two or three weeks, and with proper treatment, the patient will be able to walk, although he may feel stiffness and pain for several weeks longer. The treatment of sprains generally must be regulated by their severity. In a severe sprain, attended with much pain and inflammation, leeches should be applied, followed by hot-water fomentations, or the application of a hot linseed-meal poultice. In slighter cases, rest and cold lotions constitute sufficient treatment. In all cases of sprain of the extremities, thin pasteboard splints placed on the outer and inner surfaces of the joint, over a wet bandage previously laid round it, afford support to the part, and comfort to the patient. In sprains of the back, more decided antiphlogistic or lowering measures are required. 'After an active mercurial purge, a dose or two of Dover's Powder may be given, with salines at intervals. The diet ought to be spare. In those of vigorous constitution, the abstraction of blood may be required. Afterwards, nothing will conduce more to the comfort of the patient than well-managed fomentation of the back. Amendment will be denoted by the patient's turning in bed more freely, and seeking to sit up. At that period, stimulating liniments, or the application of the compound tincture of iodine, will be called for. When able to walk, he will be benefited by a warm plaster to his loins.' —Shaw on 'Injuries of the Back,' in Holmes's *System of Surgery*, vol. ii. p. 202.

SPRAINS, or STRAINS, are very common amongst horses, owing to the severe exertions required of them, often whilst they are young and unprepared for such work. Various muscles, ligaments, and tendons are liable to strain, but none more frequently than the large tendons passing down the back of the fore-limbs. In slight cases, cold water continuously applied for several hours gives relief; but in all serious cases, diligent fomentation with water about the temperature of 100° is preferable; or the injured part may be swathed in a thick woollen rug, kept constantly moist and warm by frequent wetting with the hot water. Perfect rest is essential, and in order to insure the relaxation of the large tendons of the horse's limbs, he may in bad cases be kept slung for several days. Blisters, hot oils, firing, and all such irritants, are on no account to be used until the inflammation abates, and the part becomes cool, and free from tenderness. Such remedies are then useful for causing the reabsorption of swelling, and perhaps also for invigorating the weakened part.

SPRAT (*Harengula sprattus*, formerly *Clupea sprattus*), a fish of the family *Clupeidæ*, very abundant on many parts of the British coast, and elsewhere in the northern parts of the Atlantic. It is smaller than the herring, being only about six inches in length when full grown, but much resembles it. It is, however, easily distinguished by the serrated belly, and by the position of the fins, the ventral fins beginning immediately beneath the first ray of the dorsal fin, and not beneath the middle of it, as in the herring and pilchard. Another easily observed distinction is the want of axillary scales to the ventral fins, which both the herring and pilchard have. The dentition is also different, and on this account Valenciennes has constituted, for the S. and a number of other species, the new genus *Harengula*, characterized by having teeth on the jaws, tongue, palatines, and pterygoids, but no teeth on



Sprat and Herring:
1, sprat; 2, herring; 3, belly of sprat; 4, belly of herring.

the vomer. The herring has teeth on the vomer. Valenciennes states also that the S. has only 48 vertebræ, whilst the herring has 56. Notwithstanding all this, an old opinion has recently been revived, and urged with some pertinacity on public attention, that the S. is the young of the herring, which, therefore, it is injurious to a more important fishery to capture. Except that it is not common to find sprats full of roe, nothing has been stated in support of this notion more to the purpose than that the serratures of the belly may possibly be a provision for the growth of the fish; a provision to which it may be remarked that nothing analogues appears in any province of nature. Nor is it wonderful that many sprats may be examined without roe being found, as the greater part of those taken on our coasts have not attained their full size. Sprats abound especially on the coasts of Norfolk, Suffolk, Essex, and Kent in November and several following months. The net used for their capture has smaller meshes than the herring-net.

Drift-net fishing is practiced as for herring, and a method called *stow-boat* fishing, in which a large bag-net is suspended between two horizontal beams beneath the boat, and about a fathom from the bottom of the water; ropes from the ends of the upper beam enabling the fisherman in the boat to keep the mouth of the bag always open and against the tide. Vast quantities of sprats are taken in this way, so that they are used as manure by farmers, although London is also very largely supplied with them, and being sold at a very cheap rate, they are a favorite article of food of the poorer classes. The Firth of Forth also produces sprats—in Scotland, called *garvies*—so abundantly that they are sold both in Edinburgh and Glasgow by measure, and cheaper than any other kind of fish. But there are many parts of the British coast where the S. is rare, some of these being parts where the herring is plentiful. Notwithstanding its cheapness, the S. is a very fine fish, of flavor quite equal to the herring, although decidedly different. Dried sprats are a very common article of provision, and sprats are also sometimes salted. The *kilkies* brought from Riga and other ports on the Baltic, are sprats cured with spices; and many of the boxes of *Sardines* which are sent to market from the west coast of France, are really filled with sprats. The value of the S. does not seem to be as yet fully appreciated in Britain. —Very closely allied to the S. is another fish (*Harengula latulus*), the *Blanquette* of the French, which is caught in great abundance on some parts of the west coasts of France.—Other species of *Harengula* are found in other seas. One of them (*H. humeralis*), which abounds in the West Indies, and southwards as far as Rio Janeiro, is much esteemed, but becomes dangerous at certain seasons, from some unknown cause.

SPREAD EAGLE. See EAGLE.

SPREE, a river of Prussia, rises near Ebersbach in the east of Saxony, on the borders of Bohemia, and after an irregularly

winding, but generally north and north-western course of 200 miles, falls into the Havel (q. v.) at Spandau. It has all the peculiarities of a stream flowing through a low and marshy region —abounding in fish, and frequently expanding into lakes, the largest of which are the *Schwielochsee* and *Müggelssee*. Its banks are flat, sometimes sandy and wooded, and sometimes rich in meadow-pastures. It becomes navigable for small craft at Kosenblatt. The principal towns past or through which it flows are Bautzen, Spremberg, Kottbus, Lübben, Beeskow, and Berlin. Its trade is very considerable. By the Friedrich Wilhelm's or Müllrose Canal, it is connected with the Oder.

SPRING, a stream of water issuing from the earth. The source of springs is the rain and snow that falls from the clouds. Very little of the water precipitated in any district finds its way immediately by rivers to the sea; the great proportion is either evaporated from the surface of the earth, and, reabsorbed by the atmosphere, is employed by plants and animals, or sinks into the earth. All loose soils and gravels greedily absorb water, which descends until it meets with a stratum through which it cannot penetrate. A pit dug into the water-charged soil would speedily fill itself by draining the water from the soil. All rocks contain water; some retain it by capillary attraction, like a sponge, others hold it merely mechanically, and easily part with it. Chalk will absorb and retain one-third of its bulk of water; and sand, on the other hand, while it will absorb as much, will part with nearly the whole amount to a well dug in it. Argillaceous deposits and compact rocks are barriers to the passage of water, and cause the superincumbent pervious strata to become water-logged, where there is no outlet. Sometimes the edges of the strata are exposed on the sides of a valley, and permit the free escape of the contained water, which pours from them over the neighboring land. But rents and fissures, as well as inequalities on the surface of the impervious beds, give the water a circumscribed course, and cause it to issue in springs.

The water, as it percolates through the earth, always becomes more or less charged with foreign matter, owing to its solvent property. Carbonate, sulphate, and muriate of lime, muriate of soda, and iron, are the most common impurities in spring-waters; magnesia and silica also frequently occur. These substances, from the evaporation of part of the water, or the escape of the carbonic acid gas, by which so large a quantity is often held in solution, are frequently deposited on the margins of the springs, or in the courses of the streams flowing from them. Such deposits are found in all so-called petrifying springs; and the hot wells of Iceland and the Azores are surrounded with basins formed of siliceous sinter which has been derived from the water. When the foreign ingredients have medicinal qualities, the springs are known as Mineral Waters (q. v.).

Springs are either associated with the superficial strata, or rise from a considerable depth. *Surface-springs* occur where the absorbent surface-deposits rest on an impervious bed, which prevents the further downward progress of the water, or where the beds through which the water flows are near the surface, as shown in fig. 1, where C and E are impervious clay-beds, and D is a bed

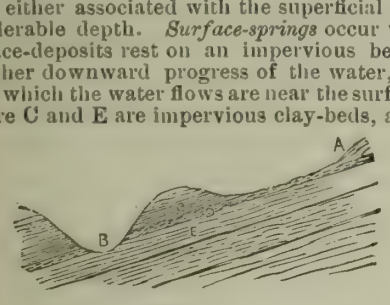


Fig. 1.

of sand or gravel, which in the upper portion is exposed on the surface, or is only overlaid by loose soil, and after being covered for some distance by the clay-bed C, makes its appearance again at B, where the valley cuts it through: here the water collected over the area, A, is discharged. Surface-springs, depending as they do so directly on the rain for supplies, are very variable in the amount of water they deliver. They frequently fail entirely in the summer, and always after great draughts. Their temperature varies with that of the district where they exist, being warm in summer, and cold in winter, as they do not penetrate below that plane in the earth's crust which is affected by the seasonal changes in temperature.

When the bed which forms the reservoir for the spring is at such a distance from the surface as to be beyond the zone of season changes, and yet within that which is influenced by the climate, the water has a temperature equal to the mean temperature of the locality where it springs. Such springs have generally a large area for the collection of the superficial water, and are consequently regular in the quantity of water they give out. They are brought to the surface by means of faults. The celebrated Well of St. Winifred, at Holywell, in Flintshire, rises through a fault in the Coal Measures. It discharges at the rate of about 4400 gallons per minute, being the most copious spring in England, and the water, in its short course of little more than a mile to the sea, is used to propel 11 mills.

Most deep wells have a lower origin than the zone of climate temperature, which in Britain is between 200 and 300 feet. It is well known that a regular increase in the temperature is observed after this zone is passed, equal to 1° of F. for every 55 feet. As wells have a temperature corresponding to that of the strata from which they spring, it follows that the deeper the spring the higher will be its temperature. Local conditions may affect the thermal state of springs, as in the case of the Geysers in the active volcanic district in Iceland, and the warm springs near Naples; but where no such local influences exist, the depth of the bed from which the water comes may be to some extent estimated by its temperature. Thermal springs occur in Britain at Matlock (66° F.) and Buxton (82°) in Derbyshire, at Bath (117°) in Somerset, and at Clifton (76°) in Gloucestershire. Artificial communications have been opened with deep-lying strata, by which the water they contain has been brought to the surface, and in these the temperature is found to increase in proportion to the depth of the bore. See ARTESIAN WELLS. The most remarkable thermal springs are the Geysers of Iceland, which are fully described under GEYSER.

Intermittent springs are sometimes produced by the ebb and flow of the tide, as at Richmond, where the rise at high water is seen in the wells which flow from the arenaceous strata on the banks of the Thames; and sometimes they depend on the supply of rain water. But there is a kind of spring the intermittences of which are believed to be owing to the structure of the internal cavities from which the supply is obtained. This will be more easily understood by a reference to the accompanying diagram (fig. 2). The large reservoir A, is fed by the rain percolating

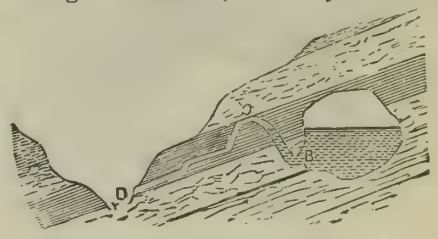

Fig. 2.

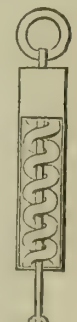
through the rock. It communicates with the surface by a siphon-shaped tube BCD. As long as the water in the reservoir is at a lower level than the arch of the siphon at C, no water can escape; but as soon as it reaches its level, the whole of the water in the cavity will be drawn off, the spring will then cease, and will only make its appearance when sufficient water has accumulated to permit the siphon again to act.

SPRING-BALANCE, THE, for determining the weight of bodies, consists of a spring in the form of a cylindrical coil, through which passes freely a graduated bar, having a hook attached to its under end, and a plate to its upper (fig.). The spring is enclosed in an oblong or cylindrical box, quite closed except at the bottom, where there is a hole just large enough to allow the free passage up and down of the graduated bar. When the instrument is to be used, it is suspended by a ring fastened to the upper part of the box; the weight to be estimated is then hung on the hook, and pulls down the rod, the button or plate at the top of which compresses the helical spring within against the bottom of the box; and the graduation corresponding to this amount of compression of the spring is read off at that part of the rod which just shows itself outside.



Spring-balance.

In another form of the spring-balance, known as Salter's Balance, a brass index-plate is attached to the side of the box, and a vertical slit through both plate and box is made from top to bottom; the weight is in this case read off on the plate by a pointer fastened to the spring, and protruding through the slit. In a third form, known as Martin's 'index weighing-machine,' the interior rod, instead of being graduated, is furnished with a rack on one side; this rack moves a toothed-wheel fastened on the side of the instrument; and this wheel, again, has at one extremity of its axis a long index, which, on the wheel being put in motion, traverses a circular dial-plate, on which the graduations of weight are marked. The advantage of this last construction consists in the arrangement of the size of the toothed-wheel to that of the dial-plate, so that, since the toothed-wheel and index make a complete revolution simultaneously, a small motion of the former may produce a large motion of the latter, and the weight of the body be much more accurately read off than can be done directly on the graduated rod. The spring-balance has one advantage

over the ordinary balance, that it does not estimate unknown weight by that which is known, and is therefore applicable to the determination of 'absolute' weight in all latitudes, at the equator as well as at the poles; but it has the great disadvantage of being considerably affected by change of temperature, the force of the spring to resist compression being diminished as the temperature increases at the rate of about $\frac{1}{5000}$th for each degree of Fahrenheit, and consequently the apparent weights of bodies must be corrected in this proportion. Various other forms of springs, semicircular, elliptical, &c., are employed instead of the helical spiral, in several French balances, but in other respects the instruments correspond. The spring-balance is also called a 'dynamometer,' from its being employed to indicate the intensity of the forces exerted by animals or machines; for this purpose, it is attached between the force and its object, the force being applied to its object solely through the medium of the dynamometer.

SPRI'NGBOK (*Antilope euchore*, or *Antidorcas euchore*), a species of antelope, nearly allied to the gazelles, very abundant in South Africa. It is an extremely beautiful creature, of graceful form, and fine colors. It is larger than the roebuck, and its neck and limbs much longer and more delicate. The general color is fulvous brown on the upper parts, pure white beneath, the colors separated on the flanks by a broad band of deep vinous red. The whole head is white, except a broad brown band on each side from the eye to the mouth, and a brown spot in the center of the face.

Springbok (*Antilope euchore*).

Two curious folds of skin ascend from the root of the tail, and terminate near the middle of the back; they are usually closed, but open out when the animal is bounding, and disclose a large triangular white space which is otherwise concealed. The S. derives its name from the prodigious leaps which it takes either when alarmed or in play, often to the height of 7 feet, and sometimes of 12 or 13 feet. Its ordinary residence is in the *karroos* or arid sandy plains; but when all pasture there is burned up, immense herds congregate together, and migrate to more fertile regions, often devastating the fields of the colonist. Mr. Pringle speaks of seeing the country near the Little Fish River specked with them as far as the eye could reach, and estimates the number in sight at once as not less than 25,000 or 30,000. Captain Cumming describes a still more extraordinary scene, a vast herd pouring through an opening among hills, in one living mass, half a mile in breadth, and so continuing for hours together. So dense are these herds sometimes in their migrations, that the lion or the leopard, which ordinarily hangs on their skirts with a view to prey, is taken prisoner, and compelled to march along in the midst. The strongest animals are generally foremost, but when satiated with food, they fall behind, and others, hungry and active, take their place. When taken young, the S. is easily tamed, and becomes very familiar, troublesome, and tricky.

SPRINGER. See ARCH.

SPRINGER, a kind of dog, regarded as a variety of the Spaniel (q. v.). It is small, elegant, usually white, with red spots, black nose and palate, long pendent ears, and small head. Its aspect is very lively, and its manners equally so. It is used by sportsmen for raising game in thick and thorny coverts. There are several breeds or sub-varieties.

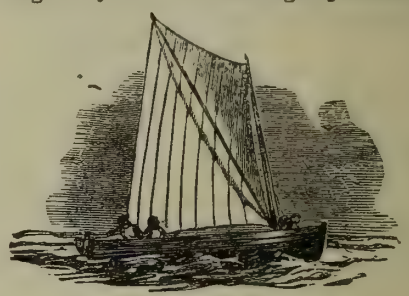
SPRI'NGFIELD, a city of Massachusetts, U. S., on the east bank of Connecticut River, 98 miles west-by-south of Boston. It is the seat of many important manufacturing establishments, which are supplied with water-power by the falls of Mill River, and among which are the United States Armory, employing about 700 men chiefly in the manufacture of rifles and carbines; foundries, manufactories of machinery, cotton-presses, steam-engines, fire-engines, locomotive-wheels, railway-carriages, india-rubber goods, &c. At the immense station-house of S. four important lines of railway meet. There is a large city hall, 26 churches, city library and museum, high school, 32 other schools, five banks, and two daily and two weekly newspapers. The town, one of the finest in New England, was settled in 1635. Pop. (1870) 26,703; (1880) 33,340.

SPRINGFIELD, the capital of Illinois, is built on a vast prairie, near the middle of the state, 178 miles south-west of Chicago, at the intersection of five railway lines. It is regularly laid out with broad streets and gardens, which have given it the name of the 'Flower City.' The State House, built in a great central square, is the principal architectural ornament. It is also the seat of the Illinois state university, and has several newspapers, foundries, machine-shops, breweries, and flouring-mills, and is the entrepôt of a rich agricultural country. Pop. (1870) 17,364; (1880) 19,746.

SPRINGFIELD, a town of Ohio, U.S., on Lagonda Creek and Mad River, 43 miles west of Columbus. It contains the Wittenberg Lutheran College, flouring-mills, iron-foundries, machine shops, woollen and paper mills, publishes several newspapers, has extensive railway connections, and a large trade in corn, cattle, and hogs. Pop. (1870) 12,652; (1880) 20,729.

SPRINGS, MECHANICAL, are very variously constructed for different purposes. The simplest form of spring is a piece of elastic metal wire, rolled on a mandrel, so as to form a continuous single cylindrical coil of any length needed. Clock and watch springs are made in flat coils, thin bands of steel being used. The *balance-spring* of watches is, however, made of fine wire often thinner than hair. Coach-springs are formed of a series of curved narrow plates of steel of different sizes, placed one over the other, the largest being at the bottom, and the others in regular succession according to size, the whole being held together with nuts and screws. These are some of the commonest forms, but very many others are in use.

SPRIT (*Spriet*, Dutch; old English verb, *sprit*, to sprout or spring out) means a pole or spar. The word occurs most frequently in the compound, bowsprit, which explains itself. When used alone, a sprit is a diagonal yard for sustaining a quadrilateral (usually



Spritsail.

square) fore-and-aft sail. The sprit's heel is held on the mast in a ring of rope, called a 'snotter,' and its head reaches to the after upper corner of the sail. The sail thus extended is a spritsail, and is frequently employed in boats.

SPRUCE. See FIR.

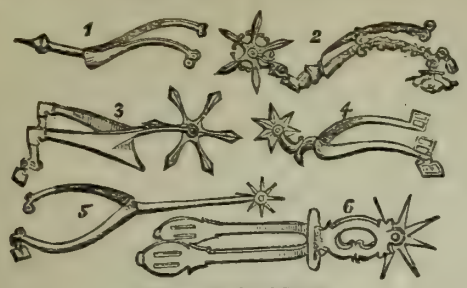
SPRUCE, ESSENCE OF, AND SPRUCE-BEER. The essence of spruce is obtained by boiling the green tops of the Black Spruce (*Abies nigra*) in water, and then concentrating the decoction by another boiling without the spruce tops. The young shoots of this fir, like most others of its family, are coated with a resinous exudation, which is dissolved in the water. The beer is made by adding the essence of spruce to water in which sugar or treacle has been dissolved, in the proportion of about four ounces of essence of spruce to ten pounds of sugar, or three quarts of treacle, and ten or eleven gallons of water, with about half a pint of yeast. Various spices are used for flavoring. A similar beverage is made largely in the north of Europe, from the buds of the Norway Spruce (*Abies excelsa*), and is known as Black Beer, that of Danzig being the most famous. The Antiscorbutic Beer of the Russian Army Pharmacopœia is made by mixing spruce tops and fresh horse-radish root with common beer, ginger and *Calamus aromaticus* being added for flavoring, and after fermentation, a little cream of tartar, tincture of mustard, and proof spirit.

SPUI'LZIE, in the Law of Scotland, is the taking away of the movable goods in the possession of another, against his will, and without any legal authority. Whenever a spuilzie has been committed, an action of damages may be brought against the wrongdoer, not only for restoration of the goods, but for all the profits which the owner might have made with the goods in the meantime. This action must be brought within three years, but the action for ordinary damages may be brought within forty years.

SPU'NGING-HOUSES are, in the Law of England, the private houses of the bailiffs, who may detain there a debtor who has been arrested for debt, for twenty-four hours, to admit of his or his friends' arranging to settle the debt; and the name is derived from the extortion often practised in this state on the debtor.

SPUR, an apparatus fastened to the heel of a horseman, for goading the horse. It is much less used than formerly. All cavalry soldiers wear spurs; but their use, except in the heat of an

actual charge, is discouraged as much as possible. In the days of chivalry, the use of the spur was limited to knights, and it was among the emblems of knighthood. To win his spurs, was for a young man to earn knighthood by gallant conduct. The degradation of a knight involved the hacking off of his spurs; and the serving before a knight of a pair of spurs on a dish, was a strong hint by his host that he had outstayed his welcome.



Various Kinds of Spurs.
(From Antiquarian Museum, Edinburgh.)
1, bronze prick spur found at Linlithgow Palace; 2, iron spur found near Bannockburn; 3, bronze spur found at Colchester; 4, brass spur found at Culloden; 5, spur found at Halidon Hill; 6, spur found in making a drain in High Street, Edinburgh.

SPURGE (*Euphorbia*), a genus of plants of the natural order *Euphorbiaceæ*, having monœcious naked flowers, the male flowers membranous, and surrounding a tricoccous stalked female flower, the whole placed within a cup-shaped involucre. The fruit has three valves and three cells, the cells one-seeded, and bursting elastically. The species are very numerous, natives of warm and temperate climates, mostly herbaceous, but some of them woody. About twelve species are natives of Britain. All contain a resinous milky juice, which in most is very acrid.

SPURGE LAUREL. See DAPHNE.

SPURGEON, CHARLES HADDON, a celebrated preacher born at Kelvedon, Essex, 19th June 1834. Intended by his family for the office of an independent minister, his own sympathies drew him towards the Baptists, whose connection he joined in 1850. He became at once an active tract-distributor and school-teacher; and, removing to Cambridge in 1851, began to deliver cottage sermons in the neighborhood. The popularity of the 'boy-preacher' was almost immediately established; and at the age of 18 he had charge of a small Baptist congregation in the village of Waterbeach. In 1854 he entered upon the pastorate of the New Park Street Chapel, London, where his preaching proved so attractive, that, in two years' time, the building had to be greatly enlarged. His hearers continuing to increase, the Surrey Music Hall was for some time engaged for his use; and finally his followers built for him his well-known 'Tabernacle,' in Newington Butts, opened in 1861. The evangelistic and philanthropic agencies in connection with this immense chapel comprise the Stockwell Orphanage, of which S. is president; a Pastor's College, where hundreds of young men are trained for the ministry under S.'s care; the Golden Lane Mission, &c. S. continues to preach in the Tabernacle to thousands of hearers, though of late repeatedly prostrated by illness. His sermons have been published weekly since 1854. They have had an enormous circulation, and many of them have been translated into various languages. He has also written *John Ploughman's Talk, Morning by Morning, Evening by Evening, The Treasury of David, Lectures to my Students, The Saint and his Saviour*, &c.; and since 1865 he has edited a monthly magazine, *The Sword and the Trowel*.

SPURN HEAD, the name given to the extreme point of a long, low, narrow, and shingly peninsula in the south-east of Yorkshire, at the mouth of the Humber, 24 miles south-east of Hull. Two light-houses have been built here, one of which is in lat. 53° 34′ 7″ N., and long. 0° 7′ 2″ E.

SPURREY (*Spergula*), a genus of plants which has been variously ranked by botanists in the natural orders *Caryophylleæ*, *Illecebraceæ*, and *Crassulaceæ*. The species are annuals, dichotomously branched, or with whorled branches; their leaves linear-filiform, in clustered whorls, with membranaceous stipules; the flowers in terminal divaricating corymbs. The flowers have a calyx of five sepals, five white petals, five or ten stamens, and five styles; the capsule is five-valved, with numerous round seeds, surrounded with a membranous border. COMMON S., or YARR (*S. arvensis*), is plentiful in corn-fields, especially on light stony or sandy soils in Britain and most parts of Europe. In some parts of Europe, a larger variety is frequently sown for fodder, and is much relished by cattle.

SPURZHEIM, JOHANN GASPAR, a German physician and phrenologist, was born near Treves, December 31, 1776. While studying medicine at Vienna, he was introduced to Dr. F. J. Gall (q. v.), whose pupil, and afterwards colleague, he became, in investigating the structure and functions of the brain (see PHRENOLOGY), in lecturing on the subject, and in writing for the press. In 1807 they settled in Paris, but parted in 1813; and next year S. came to England, where he published *The Physiognomical System of Drs. Gall and S.* (Lond. 1815), *Outlines* of the same (1815), and a treatise on *Insanity* (1817). The first of these works having been severely handled by Dr. John Gordon in No. 49 of the *Edinburgh Review*, S. proceeded to Edinburgh, and, in the lecture-room of his critic, demonstrated the reality of the anatomical discoveries which had been denied and ridiculed. To the same and other opponents, he replied in *An Examination of the Objections made in Britain against the Doctrines of Gall and S.* (Edinburgh, 1817). It was about this time, and under his tuition, that George Combe (q. v.) became a student of phrenology.

After lecturing in many British and Irish cities, S. returned, in 1817, to Paris; but from 1825 till his death, he resided much in England, teaching and defending his opinions in lectures and books. In 1832, he went to America for the same purpose, and began his labors at Boston, but was cut off by fever on 10th November in that year. Besides the English works already mentioned, he wrote: *Elementary Principles of Education* (Edinburgh, 1821; 2d ed. Lond. 1828; French translation, Paris, 1822); *Phrenology* (Lond. 1825); *Philosophical Principles of Phrenology* (1825); *Phrenology in Connection with the Study of Physiognomy* (1826); *Anatomy of the Brain* (1826), supplemented, in 1829, by an Appendix, with *Remarks on Charles Bell's Animadversions on Phrenology; Outlines of Phrenology* (1827); and *Sketch of the Natural Laws of Man* (1828). Some of these were reprinted at Boston, U. S. His French works (besides those written jointly with Gall) are: *Obs. sur la Folie* (Paris 1818); *Obs. sur la Phrénologie* (1818); *Essai Philosophique sur la Nature Morale et Intellectuelle de l'Homme* (1820); and *Manuel de Phrénologie* (1832). See *Phren. Jour.*, vol. viii. p. 126; *For. Quart. Rev.*, vol. ii. p. 15; *Memoir of S.*, by A. Carmichael (Dublin, 1833); and Combe's *System of Phrenology*.

SPY, in War, is a useful but not highly honored auxiliary, employed to ascertain the state of an enemy's affairs, and of his intended operations. Spies have been used in all wars from the time when Moses sent Joshua on such a purpose to the present time. Their employment is quite recognized by the law of nations as interpreted by Grotius, Vattel, and Martens; nor is it held to be any dishonor to a general to avail himself of their services. On the other hand, the spy himself is looked upon as an outlaw, and one devoid of honor. If taken by the enemy, he is put to death ignominiously and without mercy. As, however, the calling is so dangerous, and so little redounds to honor, it is never permissible for a general to compel by threats any person, whether of his own or the hostile party, to act as spy; but he is at liberty to accept all such services when proffered. A spy is well paid, lest he betray his employer. In the British army, spies are usually controlled by the quartermaster-general. Martial law, though distinct enough in ordering the death of a spy, is not clear in defining what constitutes a spy. A man—not of the enemy—within the enemy's lines, and in the enemy's uniform, would presumably be a spy. If in civil dress, and unable to give a good account of himself, his chance of hanging would be considerable; but if found in one camp in the uniform of the opposite side, he may not be treated otherwise than as a prisoner of war, or at least as a deserter from the enemy.

Both as regards honor and penalties, it would seem that spies ought in fairness to be divided into two classes—first, those who betray their own country to an enemy; secondly, those who, being enemies, contrive surreptitiously to obtain information by penetrating into the opposing army. The first class are traitors of a deep dye, for whom no ignominious death is too bad; but the second class are often brave men, who dare much in the service of their country. It is unfair to accord them the same treatment as the traitors.

SQUAD (diminutive of squadron) is any small number of men assembled for the purposes of drill or inspection. A troop or company of soldiers should be divided into as many squads as there are officers or sergeants at hand to drill them.—The *awkward squad* comprises recruits not yet fitted to take their places in the regimental line.

SQUADRON (Ital. *squadra*, from Lat. *quadra*, a square), in Military Language, denotes two troops of cavalry. It is the unit by which the force of cavalry with an army is always computed. Three or four squadrons constitute a regiment. The actual strength of a squadron varies of course with that of the component troops; but it ranges from 120 to 200 sabres.

In Naval Affairs, a squadron is a section of a fleet, and constitutes the command of a junior flag officer or commodore.

SQUALUS AND SQUALIDÆ. See SHARK.

SQUAMIPENNÉS. See CHÆTODONTIDÆ.

SQUARE, in Military Evolutions, is the forming of a body of men into a rectangular figure, with several ranks or rows of men facing on each side. With men of ordinary firmness, a square should resist the charges of the heaviest horse. The formation is not new, for a Grecian syntagma was a solid square of 16 men in every direction; but in modern warfare, the solid square having been found cumbrous, has been abandoned for the hollow square, with officers, horses, colors, &c. in the centre. The front rank kneels, and the two next stoop, which enables five ranks of men to maintain a rolling fire upon an advancing enemy, or to pour in a murderous volley at close quarters.

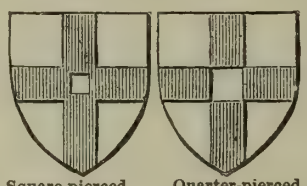
SQUARE, in Geometry. See PARALLELOGRAM.

SQUARE AND SQUARE ROOT are particular cases of *Involution and Evolution* (q. v.) in which the second power and root are alone involved. The process by which the square root of a number is obtained resembles division, differing only by the the circumstance, that the divisor is changed at each successive step. The rule adopted in arithmetic is deduced from algebra in the following manner: The square of $a + b$ is $a^2 + 2ab + b^2$, which may be written $a^2 + b\,(2a + b)$; and to find the square root of the latter, we have merely to subtract a portion (a^2), taking care that it be a square number, and forming a divisor with twice the square root of this portion ($2a$) increased by (b) the remainder of the root (which, in arithmetic, must be found by trial as in division), and putting (b) the remainder of the root now found, in the quotient, proceed as in division. This mode of obtaining a divisor from the part of the root already obtained (a), and the part next to be obtained (b), and employing it, must be repeated till the whole square root is found. In the extraction of the square root in arithmetic, it is assumed that the squares of the nine digits are known; and also that the square of a number contains either twice, or one less than twice, as many digits as the number itself contains; the former being the case when the square number has an *even* number of digits, the latter when the number of digits is *odd*. By dividing, then, a number into periods of two figures each, we can at once see how many digits its root contains. To illustrate the method of operation adopted in arithmetic and algebra, let the square root of 128,881 be required; remembering that the square of $a + b + c$ is $a^2 + 2ab + b^2 + 2\,(a + b)\,c + c^2$:

	12·88·81	(300 + 50 (or 350) + 9 = 359	a =	300	12·88·81 (300 = a
$(a^2 =)\ 300^2$ =	90000	$a + b$ (or $a + b$) + c		300	90000 50 = b
	38881		$2a + b$ =	650	)38881 9 = c
$(2ab + b^2 =)\ 2 \times 300 \times 50 + 50^2$ =	32500			50	32500 359
$(2\,(a + b)\,c + c^2)$	6381		$2\,(a + b) + c$ =	709	)6381
$2 \times 350 \times 9 + 9^2$ =	6381				6381

In the common arithmetical mode, the zeroes are omitted, and we substract from 12 the square nearest to it, not recognizing the portion of the root, 3, as more than a digit of units, till the next period, 88, has been brought down for the second step, when it is evident that the 3 is *at least* 3 tens, and consequently the 6 in the divisor represents 60; similarly, it is only at the commencement of the third step that we find the 5 to represent 50, and the 3, 300. A comparison of the above examples will show the agreement and difference between the two modes.

SQUARE-PIERCED, in Heraldry, a term used to designate a charge perforated with a square opening, so as to show the field. A cross square-pierced is often improperly confounded with a cross quarter-pierced, where the intersecting part of the cross is not merely perforated, but entirely removed.



Square-pierced. Quarter-pierced.

SQUARES, METHOD OF LEAST, in Astronomy, the best mode hitherto discovered of obtaining the most correct result from a number of observations upon any phenomenon. These observations are assumed to differ slightly from each other, and to be all of equal value, that is, taken under equally favorable conditions, and with equal instruments. The ordinary and long-established mode of approximating to the truth in such cases, is by finding the arithmetic mean, and accepting it as the correct result; but in all cases where the result required does not come directly from observation, but requires to be discovered by calculation, this simple and useful method is inapplicable, and that of 'Least Squares,' which gives more probable corrections, is adopted. The method is founded on a theorem which was first propounded by Legendre in 1806, more for the sake of insuring uniformity among calculators than from any belief in its intrinsic value; but it was afterwards thoroughly discussed and proved by Gauss and Laplace, that 'if the mean of a number of distinct observations be so taken, that the sum of the squares of its differences from the actual observations (generally designated *errors*) shall be a minimum, this mean will be, under these circumstances, the correctest obtainable value.'

The process by which the mean thus obtained is shown to be the most trustworthy approximation is too long for insertion here; but it may not be undesirable to give an example of the most common form of the method as occurring in astronomy. Let there be a series of equations—

$$\begin{aligned} X &= x + y + 2z, \\ X_1 &= 3x + 2y + 5z, \\ X_2 &= 4x + y + 4z, \\ X_3 &= -x + 3y + 3z; \end{aligned}$$

where the unknown quantities are x, y, and z, connected by various (the more the better) equations with X, X_1, &c., quantities which must be determined by actual observation. Suppose the values of the quantities thus found to be 3, 5, 21, and 14, then, since by hypothesis all these four observations are erroneous, the errors are $3 - X$, $5 - X_1$, $21 - X_2$, $14 - X_3$, or

$$\begin{aligned} 3 &- x - y - 2z, \\ 5 &- 3x - 2y - 5z, \\ 21 &- 4x - y - 4z, \\ 14 &+ x - 3y - 3z. \end{aligned}$$

The squares of these four errors are now added together; and, to find the values of x, y, and z, which will render this sum (call it S) a minimum, we must differentiate S with respect to x, y, and z in turn, and putting each of these partial differential coefficients equal to zero, we obtain the three equations, $-88 + 27x + 8y + 30z = 0$; $-76 + 8x + 15y + 25z = 0$, and $-157 + 30x + 25y + 54z = 0$; from which the most trustworthy values of x, y, and z, can be found by common algebra.—See a paper by Mr. Ellis in the *Cambridge Transactions*, vol viii.

SQUASH. See GOURD.

SQUATTERS, the name given in the Australian colonies to the sheep-farmers who occupy the unsettled lands as sheep-runs under lease from government. See NEW SOUTH WALES, VICTORIA.

SQUID. See CALAMARY.

SQUIER, EPHRAIM, GEORGE, LL.D., American author and archæologist, was born at Bethlehem, New York, June 17, 1821. In his youth, he was a school-teacher and engineer, and in 1840 was editor of *The Mechanic*, at Albany; in 1843, of the Hartford *Journal;* and in 1844, of the *Scioto Gazette*, in Ohio. His attention being attracted to the antiquities of the Scioto Valley, he made an exploration of similar monuments through the Mississippi Valley, an account of which was published in 1848, forming the first volume of the *Smithsonian Contributions to Knowledge*. He made similar explorations in New York and Connecticut; and on being appointed *chargé d'affaires* to Guatemala and other states of Central America, he used his official position as a means of making extensive geographical and archæological explorations in those interesting regions. On visiting Europe in 1851, he was honored with the gold medal of the French Geographical Society, and made a member of other learned societies. Returning to America (1853), he surveyed a railway route through Honduras, and drew up the treaty between that country and England for the retrocession of the Bay Islands. Among his works are—*Nicaragua: its People, Scenery, Ancient Monuments, and Proposed Interoceanic Canal* (1862); *The Serpent Symbol, or Worship of the Reciprocal Principles of Nature in America* (1852); *Notes on Central America* (1854); *Waikna, or Adventures on the Mosquito Shore* (1855); *Question Anglo-Americaine* (1856); *The States of Central America* (1857); the Report of the Honduras Survey (1859); a work on Tropical Fibres (1861); *Honduras* (1870); *Peru* (1876); articles in the *Encyclopædia Britannica;* &c.

SQUILL (*Scilla*), a genus of bulbous-rooted plants of the natural order *Liliaceæ*, nearly allied to Hyacinths, Onions, &c., and having a spreading perianth, stamens shorter than the perianth,

smooth filaments, a 3-parted ovary, and a 3-cornered capsule with three many-seeded cells. Many of the species are plants of humble growth, with scapes like those of Hyacinths, and beautiful flowers. Of these, two are natives of Britain: *S. verna*, which is common on the western and northern coasts, and particularly in Orkney and Shetland, and has fragrant flowers of a deep blue color; and *S. autumnalis*, which grows chiefly on the coasts of the south of England, and has pinkish purple flowers. *S. bifolia*, is a very doubtful native of Britain, but adorns hill-pastures and borders of woods in many parts of Europe with its blue flowers in early spring. *S. amœna* is another very beautiful species found in many parts of Europe. Few plants are better adapted than these for the adorning of flower-borders, or for house-culture.—Very different in habit from these is the OFFICINAL S. (*S. maritima*, or *Urginea Scilla*), a native of the sandy shores of the Mediterranean, which has a scape from two to four feet high, with a raceme of many whitish flowers, and large leaves. The bulb is of the size of a man's fist, or sometimes as large as a child's head, and contains a viscid juice so acrid as to blister the fingers if much handled, whilst the vapor arising from it irritates the nose and eyes. Squill was used in medicine by the ancients, and continues to be so still. The bulb is dug up in autumn, divided into four parts, the center being cut out as being inert, and the remainder being cut into thin slices, which are quickly dried by a gentle heat. It is imported from Malta and other Mediterranean ports; also from St. Petersburg and Copenhagen. The dried slices are white, or yellowish white, slightly translucent, scentless, disagreeably bitter, brittle, and easily pulverizable if very dry.

Squill.

The chemical composition of squill is not accurately known, its most active principle being a very acrid, poisonous, resinoid substance, soluble in alcohol, but not in ether. Whatever its active ingredients may be, they are taken up by alcohol, vinegar, and the dilute acids. This medicine is prescribed as a diuretic and expectorant, and occasionally as an emetic; but it must be recollected that in moderately large doses it acts as a narcotico-irritant poison, 24 grains having proved fatal. When given as a diuretic, it is usually prescribed in combination with digitalis and calomel, when it seldom fails to produce an increased secretion of urine, while at the same time it promotes the absorption of the effused fluid in the dropsy, which is generally present when diuretics are ordered. Its use is counter-indicated if inflammatory symptoms are present. Its dose as a diuretic is from one to three grains of the powdered bulb, or about twenty minims of the tincture. As an expectorant, it is much employed in the subacute stages and chronic forms of pulmonary affections, and is very serviceable in bronchitis and pneumonia of children. From its property of promoting the secretion of mucus, it gives relief by facilitating the expectoration in cases of asthma, &c., in which the sputa are viscid. In these cases, it is usually associated with some of the more stimulating expectorants, as senega or susquicorbonate of ammonia. As an expectorant, the dose of the powdered squill should not exceed one grain, repeated several times daily. For children, the syrup, in doses of from ten to thirty minims, may be given. As its action as an emetic is uncertain, it should not be prescribed with the view of inducing vomiting, if other and more certain remedies are at hand.

SQUI'LLA, a genus of Crustaceans of the order *Stomapoda*, the type of a family, *Squillidæ*, to which the names *Mantis Crab*, *Mantis Shrimp*, and *Sea-mantis*, are popularly given, from the strong general resemblance to the insects of the genus *Mantis* (q. v.). The form is elongated; the carapace only covers the anterior part of the thorax, the latter part of which is formed of rings like the abdomen; the eyes are carried on stalks; the claws are very large, and furnished with spines, forming powerful instruments of prehension; the tail is expanded into a broad fin. The species are numerous, and mostly inhabit tropical seas. A species about seven inches long, *S. mantis*, is found in the Mediterranean. The *Squillæ* are extremely active, and very bold and voracious.

SQUINCH, small arches or corbelled courses across the angles of square towers, to bring in the form to carry an octagonal spire, lantern, &c. See PENDENTIVE.

SQUI'NTING, or STRABI'SMUS, is a well-known and common deformity, which may be defined as a want of parallelism in the visual axes, when the patient endeavors to direct both eyes to an object at the same time. The squint is said to be *convergent* when the eye or eyes are directed towards the nose, and *divergent* when they are directed towards the temple, and is termed *single* or *double* according as only one eye or both are displaced. The divergent form is comparatively rare, except in consequence of a prolonged loss of sight of one eye. The causes of this affection are various. Intestinal irritation, such as the presence of worms, will often induce it slightly in children. In other cases it may be traced to the temporary cerebral irritation produced by teething; and it is a very common symptom in hydrocephalus and other serious head-affections. Amongst other causes are a want of equal normal visual power in both eyes, in extreme short-sight; but from extensive observation with the ophthalmoscope, Mr. Dixon, surgeon to the Royal Ophthalmic Hospital, Moorefields, has come to the conclusion, that 'in the great majority of instances of confirmed squint existing in children, the optic nerves themselves are ill-developed, being usually smaller than natural, of a more or less oval form, and of a dusky color.'—Holmes's *System of Surgery*, vol. ii. p. 890. If the squint is only temporary and possibly arises from intestinal irritation, the bowels must be well cleared out, and tonics subsequently given. If it is due to some peculiarity in the visual focus of the eyes, it may be removed by the judicious use of glasses. 'In every case,' says Mr. Dixon 'a careful ophthalmoscopic examination is the first duty of the surgeon; and he should also take every possible care to ascertain that no organic disease exists in the brain or orbital nerves; and that there is no tumor in the orbit, mechanically burdening the movements of the eye.' The surgical operation for the cure of squint consists in the division of the muscle which, by permanently drawing the eye inwards or outwards, and overpowering its antagonistic muscle induces the deformity. It is better to dispense with the use of chloroform in this operation, if the patient have sufficient nerve to bear the operation without flinching, as in that case the doubt that sometimes arises as to whether the muscle has been sufficiently divided can be at once solved by directing the patient to attempt inversion of the eye; but in the great majority of cases, chloroform is found necessary.

SQUINTS, narrow apertures cut in the walls of churches (generally about two feet wide), to enable persons standing in the aisles to see the high altar. These openings are always in the direction of an altar.

SQUIRE, an abbreviated term for Esquire (q. v.). The same word is also popularly applied in England to country gentlemen; and in the United States of America to magistrates and lawyers, and sometimes to judges and justices of the peace.

SQUIRREL (*Sciurus*), a Linnæan genus of rodent quadrupeds, now the family *Sciuridæ*. They belong to the section of Rodentia having perfect clavicles, and are further characterized by a long bushy tail; the fore-paws furnished with four toes, which have curved claws, and a tubercular thumb; the hind-legs long, their feet with five toes; two incisors in each jaw; four molar teeth on each side in each jaw, simple, with tuberculous crowns, and a fifth in the front of the upper jaw, which soon falls out. Most of the species commonly carry the tail curved over the body, whence the Greek name *Skiouros* (*skia*, a shade, and *oura*, a tail), of which the English *squirrel* is a corruption. The species are numerous, and are found in almost all parts of the world, except Australia; some inhabiting temperate and even cold regions, whilst some belong to tropical countries. Squirrels are very active and lively creatures, at once shy and pert, very adroit in hiding themselves on the appearance of danger, but resembling monkeys in their inquisitive curiosity. They inhabit woods, and mostly spend their lives in trees, which they climb with wonderful agility, running along the branches, and leaping from tree to tree. Their running is a kind of bounding, and the tail is then stretched out, as it is also in their leaps from branch to branch, which are often to great distances. The Flying Squirrels are already noticed. Even the true squirrels resemble them in spreading out their limbs and tail to the utmost in leaping, particularly when they descend from a high branch to the ground, and they thus leap from a great height without injury.

Some species, however, seldom ascend trees, but burrow in the ground, and are further distinguished by having cheek-pouches, whilst the tail is shorter than in the tree squirrels, and its hair not so distinctly arranged in two lateral rows. These *Ground Squirrels* form the genus *Tamias*. All the squirrels feed on fruits and seeds, the young shoots of trees, and other such vegetable substances; although they sometimes vary their diet by plundering birds' nests, and not only sucking eggs, but devouring young birds. They are also fond of the larvæ of insects. In eating, they often sit erect, and hold the food in the fore-paws. The hardest nut presents no difficulty to their sharp strong teeth. Many of the species, and probably all those of temperate and cold climates, lay up stores for winter.—The COMMON S. (*S. vulgaris*) of Europe is a beautiful little animal, about eight inches and a half in length

without the tail, which is fully six inches long, besides being apparently lengthened by its long hair. It is brownish red on the upper parts, and white beneath; the color changes more or less in winter to a grayish brown, and in northern countries to gray, and even to white. The long hairs which fringe the ears, and are drawn up into a fine point, are longer in winter than in summer. The Common S. is widely distributed over the northern parts of

Common Squirrel.

the Old World, and is plentiful in England, and in some of the southern parts of Scotland, into which, however, it is said to have been introduced. It is generally protected and its presence desired in the vicinity of mansions; although it often does considerable injury in plantations by gnawing off the top-shoots of trees, particularly of firs and pines. Morning is generally the time of the squirrel's greatest activity, except in winter, when it prefers the warmest hours.

Although numbers are often seen together, they live mostly in pairs, which seem to continue attached throughout life. The S. makes a beautiful nest of moss, twigs, and dry leaves, curiously interwoven, most frequently in the fork of a tree at a considerable height from the ground. Here the young are produced, three, four, or five at a birth, in the middle of summer. They continue with their parents till the spring of next year. The winter hoards of the S., containing nuts, beech-mast, grain, and the like, are usually in holes in the ground about the roots of trees, not far from its ordinary abode, the same pair of squirrels having often a number of these hoards. The seeds of firs form a very considerable part of the winter-food of squirrels, and to obtain them, the scales are gnawed away from the cones. The S. is easily tamed, and is an amusing pet. It is almost in constant motion, except when asleep.—The only other European species is the ALPINE S. (*S. alpinus*), a native of the Alps and Pyrenees, about the same size with the Common S., deep brown, speckled with yellowish white.—North America abounds in species of squirrels. The GRAY S. (*S. migratorius*) occurs in the northern parts of the United States, and as far north as Hudson's Bay. It is much larger than the European S., the whole length with the tail being nearly two feet. It is usually light gray, with yellowish-brown head, and logitudinal stripes of yellowish brown, but it is often found almost entirely black. Its habits are very similar to those of the Common S., but it is more gregarious. Gray squirrels sometimes visit corn-fields in large numbers, and make great devastation. In Pennsylvania, an old law gave a reward of threepence a head for every S. destroyed, and in the year 1749 no smaller a sum than £8000 was paid out of the treasury on this account, so that 640,000 squirrels must have been killed. Hosts of S. sometimes leave their native woods, and migrate like Lemming (q. v.) of Northern Europe, whether urged by scarcity of food or through some other unknown impulse. These migrations usually occur in autumn, and are regarded with great horror by farmers.

The squirrels advance in a straight course; mountains are no impediment, and although they swim with difficulty, they cross large rivers and the narrow bays of lakes.—The CAROLINA GRAY S. (*S. Carolinensis*) is a rather smaller species, abundant in the south-eastern parts of the United States, where its flesh is highly esteemed. A number of other species are found in different parts of North America, and very beautiful species occur in tropical countries, some of which live mostly in palms.—Of Ground Squirrels, several species are natives of North America, of which the best known is the CHIPPING S., HACKEE, or CHIPMUCK (*Tamias Lysteri*), abundant in almost all the eastern parts of the United States, and as far as 50° N. lat. Its length, with the tail, is fully ten inches; the general color gray, longitudinally striped with black and yellowish white. It derives its name from its *chipping* or chattering cry, which is like that of a young chicken. It seldom ascends trees; and is not troublesome to the farmer, as it does not attack standing corn, but gleans the fields, and feeds on fallen nuts in the woods. It burrows near the roots of trees, and several squirrels generally inhabit one burrow, which is deep and winding, and in which stores are laid up for winter use. In carrying nuts or other food to its retreat, it makes use of its cheek-pouches, cramming and distending them to the utmost.—A very similar species (*T. striatus*) inhabits Siberia.

The fur of some of the American squirrels is an article of commerce. It is one of the chapest kinds of fur.

SQUITCH. See COUCH GRASS.

S'RADDHA (from the Sanscrit *s'raddhâ*, faith, belief) is the name of the funeral ceremony of the Hindus, in which balls of food, and water, are offered to the deceased ancestors of the sacrificer, or to the *Pitr'is* or manes collectively. It is especially performed for a parent recently deceased, or for three paternal ancestors, and is supposed necessary to secure the ascent and residence of the souls of the deceased in a world appropriated to the manes. But this ceremony is observed also on occasions of rejoicing as well as of mourning; and hence various S'râddhas are enumerated—viz. 1. S'râddhas which are *constant*, or the daily offerings to the manes in general, and those offered on the eighth lunation of every month; 2 S'râddhas which are *occasional*, as those for a relative recently deceased, or those to be performed on various domestic occurrences, as the birth of a son, &c.; and 3. S'râddhas which are *voluntary*, performed for a special object. such as the hope of religious merit, &c. The proper seasons for the worship of the manes collectively are the dark fortnight or period of the moon's wane, the day of the new moon, the summer and winter solstices, eclipses, &c. The presentation of the ball of food to the deceased, and to his progenitors in both lines, is the office of the nearest male relative *and is the test and title of his claim to the inheritance.*—See for further detail, H. H. Wilson's *Glossary of Judicial and Revenue Terms* (Lond. 1855), under *S'râddha.*

S'RAVAKA (from the Sanscrit *s'ru*, to hear) is the name of the disciples of Buddha, who, through the 'hearing' of his doctrine, and by practising the four great Buddhistic truths, attain to the qualification of an Arhat, or Buddhist saint. From among the number of the disciples of Buddha, 80 are called the *Mahâs'râvakas*, or the great S'râvakas. The S'râvakas are entitled to the predicate *Ayushmat*, or 'one possessed of (long) life.'

S'RUTI (from the Sanscrit *s'ru*, here, hence, literally, the hearing, or that which is heard) is, in Sanscrit Literature, the technical term for all those works which are considered to have been revealed by a deity. It applies, therefore, properly speaking, only to the Mantra and Brâhmana portion of the Vedas; but at a later period it is applied likewise, if not especially, to the Upanishads. See VEDA.

SS, COLLAR OF, a collar composed of a series of the letter S in gold, either linked together or set in close order, on a blue and white ribbon, with the ends connected by two buckles and a trefoil-shaped link, from which hangs a jewel. Such collars have been much worn in England by persons holding great offices in the state, as well as by the gentry of various ranks, from esquires upwards. They are of frequent occurrence on sculptured monuments; but the origin of the device has not been satisfactorily explained. Among the numerous conjectures which have been formed regarding its meaning, one is, that the letter S stands for 'souveraigne,' the favorite motto of Henry IV.; others have suggested 'seneschal;' and Mr. Planché hints that it may, with equal probability, owe its origin to the swan of the De Bohuns, that badge being found in one of the earliest examples of this collar (1402), pendent round the neck of the poet Gower, in St. Saviour's Church, Southwark. The collar had, without doubt, originally a Lancastrian character. Collars of SS are still worn, with certain recognized distinctions, by the Lords Chief Justices, the Lord Chief Baron of the Exchequer, the Lord Mayor of London, the Heralds and the Sergeants-at-Arms.

STA'BAT MA'TER, a celebrated Latin hymn on the Crucifixion, beginning

Stabat mater dolorosa
Juxta crucem lacrimosa
Dum pendebat filius.

The *Stabat Mater* forms part of the service of the Roman Catholic Church during Passion-week. Its authorship has been assigned to Jacopone, a Franciscan who flourished in the 13th century. It has been set to music by many composers of eminence. Pergolese's *Stabat Mater*, written by that eminent musician on his deathbed, is justly celebrated for its pathos and expression. Rossini's more secular *Stabat Mater* is also well known to all lovers of music.

STABI'LITY AND INSTABI'LITY. When a body rests upon a surface, in such a manner that a vertical from its center of gravity falls within the largest polygon which can be formed by joining the various points of contact of base and surface, it will stand; but if the contrary is the case, it will fall, unless extraneously supported. If the base of the body be a plane, and the supporting surface convex, or *vice versâ*, or if both base and surface be convex, there will be only one point of support, and if the

body be at rest its center of gravity must be vertically over the point of contact. Should a body so placed receive a slight impulse, it will either oscillate to and fro, ultimately returning to its original position, or remove further and further from its original position, showing a tendency not to return, or appear indifferent to any one position. In the first case, the body is said to be in *stable*, in the second case, in *unstable*, and in the third, in *neutral* equilibrium. Fig, 1 shows various illustrations of these

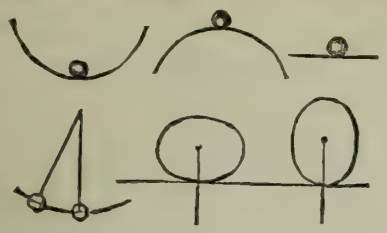


Fig. 1.

three species. It will appear at once that the predetermining cause of equilibrium being of one rather than of another of these species, is the tendency of the center of gravity of every body to seek a lower position; and the illustrations show that in stable equilibrium the center of gravity of the body may, and in unstable equilibrium may not, attain a lower position, while in neutral equilibrium its position continues unaltered.

In illustration of the mode in which the species of equilibrium possessed by a body which has received a slight impulse is determined, let us take the case of a body with a spherical base resting upon a spherical surface (fig. 2); let S and O be the the centers of

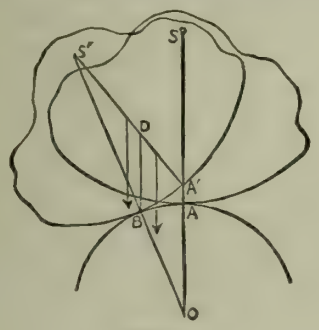

Fig. 2.

the spherical surfaces respectively, and let A be their point of contact (the center of gravity being consequently in the line SA, or in it produced towards S, and after displacement, in the line S'A', produced if necessary), let the new position of S, after the body has been slightly displaced, be S', and the new point of contact B; join OS, OS', S'A', and draw BD vertically, that is, parallel to OC. Then $A'D : A'S' :: OB : OS'$, or $A'D = \frac{A'S \times OB}{OS'}$, that is, A'D = the product of the radii of the two surfaces divided by their sum. Now, should the center of gravity of the displaced body fall between D and A', it will have a moment round B tending to restore the body to its former position (*stable equilibrium*); should the center of gravity be beyond D from A', its moment round B will tend to increase the displacement (*unstable equilibrium*); while, if it fall in the line BD, it will still be above the point of contact, as it was at first, and there will be no tendency either to return to, or to move further from, the original position (*neutral equilibrium*). These conditions may be briefly expressed by the following formulæ, in which R is the radius of the supporting surface, r of the spherical base of the body, and X the distance of the center of gravity from the point A; when equilibrium is stable, X is less than $\frac{R \times r}{R + r}$; when unstable, X is greater than $\frac{R \times r}{R + r}$; and when neutral, $X = \frac{R \times r}{R + r}$. From these formulæ, the conditions of equilibrium of a body, with a spherical base on a plane surface, can be at once deduced by making $R = \infty$, the three species of equilibrium being then represented in order by X less than r, X greater than r, and $X = r$; the simplest illustrations of these being respectively a segment of a sphere, a tall cone on a spherical base, and a sphere.

STACCA'TO (Ital. detached), in Music, a term implying a detached, abrupt mode of performance. A certain amount of time is subtracted from the proper value of any note played staccato, and a rest substituted. A dot placed over a note indicates that it is to be played staccato: . A dash implies a greater degree of staccato: , and a very slight degree of staccato is expressed by uniting the dot with the slur: ; the slur being the sign of a *legato* expression, the converse of staccato.

STA'CHYS, a genus of plants of the natural order *Labiatæ*, containing a great number of species, mostly European, having a ten-ribbed calyx, with five nearly equal teeth, the upper lid of the

Betony (*Stachys officinalis*).

corolla entire, and the lower lip three-lobed. Several species are natives of Britain. *S. sylvatica* is very common in shady places, a coarse herbaceous plant, sometimes called *Hedge Nettle*, with stem 2—3 feet high, ovate heart-shaped leaves on long stalks, whorls of purple flowers, and unpleasant smell. *S. palustris* is another very common British species, growing in moist places, and sometimes proving a very troublesome weed in meadows. The plant was formerly used as a vulnerary, and has therefore the English name *Woundwort*. Several species are not unfrequently to be seen in flower-gardens. To this genus some botanists refer the COMMON BETONY or WOOD BETONY (*S. betonica*, or *Betonica officinalis*), plentiful in woods and thickets in the southern parts of Britain, a plant one or two feet high, with hairy stem, oblong heart-shaped leaves, whorls of purple or white flowers, and a fetid smell. It was formerly much used in medicine. The roots, in small doses, are emetic and aperient.

STA'DÉ, a small but very ancient town, formerly fortified, in Prussian Hanover, near the mouth of the Schwinge, a tributary of the Elbe. Pop. (1880) 9700.

The *Stade Dues* were a toll or duty which used to be charged by the Hanoverian government on all merchandise carried up the Elbe to Hamburg. The original duties, as regulated by a treaty of date 1691, were comparatively light, but they had been gradually increased till they brought to Hanover a revenue of £40,000. After several modifications in 1844 and 1854, this vexatious toll was finally abolished in 1861, Hanover receiving a compensation equivalent to £30,000 annually, of which Great Britain paid one-third, another third was contributed by Hamburg, and the remaining third divided proportionally among the other countries that traded to the Elbe.

STA'DIUM, the course set apart for foot-races and all the other games excepting horse-racing, which were wont to be celebrated at Olympia and other places in Greece; the horse and chariot races being held in the *Hippodrome*, (q. v.). The stadium was of the same form as the hippodrome, and the arrangement of the spectators was similar. The distance between the starting-point and the goal was, in the Olympic stadium, about 600 Greek feet, and the stadia of other places adopted the dimensions of that at Olympia. This distance of 600 Greek feet was adopted as the chief Greek measure of length, and called a *stadium*. It was equivalent to 625 Roman feet, or 125 Roman paces; hence the Roman mile of 1000 paces contained exactly 8 stadia.

STA'DTHOLDER (Ger. *statthalter*, Dutch *stadhouder*, lieutenant or governor of a province). In the German cantons of Switz-

erland, the name is given to the second civil officer, who ranks next to the landamman. In the republic of the Seven United Provinces, the chief magistrate or president of the union was called the stadhouder. In the 16th c., when the tyranny of Ferdinand, Duke of Alva, governor under Philip II., drove the principal towns into revolt, they chose William, Prince of Orange, for their governor, and with the view of letting it be understood that the revolt was not against Philip, but against Alva, they conferred on William no higher title than that of Stadhouder. On the assassination of William in 1584, the provinces of Holland, Zeeland, and Utrecht agreeing to have one stadhouder, appointed Maurice of Nassau to that office, which came tacitly to be looked on as hereditary. The stadhouderate thus instituted was considered to be at an end or in abeyance on the extinction of the line of William I., by the death of William III. However, on the triumph of the Orange party over the Republican in 1747, William IV., descended from a collateral branch of the House of Nassau, was proclaimed stadhouder, captain-general, and admiral-in-chief of the Seven United Provinces, those dignities being made hereditary in his family. His son, William V., the seventh stadhouder, was driven from his country by the French in 1795, and resigned his office in 1802; since which time, the stadhouderate has never been revived, the Netherlands having, at the Congress of Vienna, been formed into a kingdom.

STAEL-HOLSTEIN, Anne Louise Germaine Necker Baronne de, was born at Paris, April 22, 1766. Her father was the celebrated M. Necker (q. v.), finance minister of Louis XVI., in the times immediately preceding the Revolution. Her mother was a woman of severe character, and from her earliest years subjected her to a discipline almost puritanic in its rigor. The daughter, in consequence, had no very warm attachment for her; but for M. Necker, who softened as he could by his indulgent tenderness the harsh rule of his spouse, she entertained the most ardent affection, regarding him then and always with what was almost an idolatry of fondness and admiration. Her talents were precociously developed, and whilst yet the merest girl, she would listen with eager and intelligent interest to the conversation of the Parisian *savans* who used to frequent the house of her father. In 1786, she was married to the Baron de Staël-Holstein, Swedish minister at Paris, an elderly gentleman with whom her happiness was probably not great, inasmuch as, a few years after, a separation between them took place, two sons and a daughter having been meantime the fruit of their union. In 1788, she issued her first work *Lettres sur les Ecrits et le Caractère de J. J. Rousseau*, which are rather a passionate eulogy of a girlish idol than a just and discriminating criticism.

Her sympathy with the Revolution in its earlier stage of promise was profound, but gave place, as its later enormities were developed, to a reaction of horror, which is vividly set forth in her subsequent *Considérations sur la Révolution Française*. Her grief was extreme on the failure of the attempt to escape on the part of the royal family, and she engaged in a secret scheme for securing them a flight to England. This, however, came to nothing; and she then, along with her father, betook herself to Switzerland, his native country. The news of the king's execution inexpressibly shocked her; and she sought to save the life of the queen by publishing *Réflexions sur le Procès de la Reine, par Une Femme*, which, however, was too late to be effective. In 1795, she published at Lausanne, under the title *Recueil de Morceaux Détachés*, a collection of her juvenile writings; and the year after, a treatise *De l'Influence des Passions sur le Bonheur des Individus et des Nations*, a work full of originality and genius. In 1797, order having been re-established under the Directory, she was once more in Paris. From the first, she distrusted the designs of Napoleon, and her *salon* became the headquarters of the anti-Bonapartist faction. In vain she was offered restitution of two million livres since 1788 due to her father from the royal treasury; she scornfully declined the bribe; and as neither fear nor favor could lead her to disguise her hostility to him, it seemed well for Napoleon to rid himself of her. She was forbidden to live in Paris, and subsequently (1802) exiled from France itself. Meanwhile, she had greatly increased her reputation by the publication of her romance of *Delphine*, and a work *Sur la Littérature considerée dans ses Rapports avec l'Etat Moral et Politique des Nations*. She now, for two years, traveled in Italy and in Germany, making at Weimar the acquaintance of Goethe, Schiller, Herder, Wieland, &c. The death of her father in 1804 recalled her to Coppet, in Switzerland. Subsequently, she was permitted to return to Paris, and there, in 1807, she published her famous *Corinne, ou l'Italie*, the success of which was instant and immense, and won for her a really European reputation.

As a bitter in the sweet of fame, however, fresh difficulties with Napoleon occurred, and she was banished anew to Coppet. Her son, the Baron Auguste, then 17 years old sought to intercede for his mother in a personal interview granted him by the emperor, whose inexorable deliverance on the occasion is too characteristic and amusing to be omitted: 'Avec l'exaltation de sa tête la manie qu'elle a d'écrire *sur tout et à propos de rein*, elle pouvait se faire des prosélytes; j'ai dû y veiller.' And in candor it is to be admitted, despite of the shrieks which have ever since been put forth about Napoleon's so-called 'ungenerous persecution,' that he acted on the dictate of a sound prudential policy. A woman who would keep no terms with him, who was uncompromising and fearless, and an influence by the weight of her genius and reputation, was clearly in Paris, of all places, a phenomenon not to be tolerated by the head of a government such as his, more or less the sport of the hour, as always in its basis precarious. After this, when disgusted with Coppet, where she found herself subself subjected to a petty *surveillance*, Madame de S. rushed restlessly over Europe to Vienna, Moscow, St. Petersburg, thence through Finland to Stockholm, and afterwards to London, where, in 1813, she published her great book, *De l'Allemagne*, which had previously been suppressed in Paris. As the first decisive revelation of the genius of Germany to the French people—somewhat as the earlier writings of Mr. Carlyle revealed it to the reading public of Britain—this may perhaps rank as the most important and influential of her works. Of her various experiences of travel, an interesting record is preserved in her *Dix Années d'Exil*.

At the Restoration, she returned to her beloved Paris; from Louis XVIII. she met with a most gracious reception; and restitution was granted her of the two millions on her father's account before mentioned. Soon after, her health failed; she sought its restoration in a visit to Italy in 1816, but without effect, and on July 14, 1817, she died at Paris. She was buried at Coppet; and by her will the fact was revealed that, in 1812, she had privately married M. de Rocca, a French officer of hussars, aged 25; which may be looked upon as something of an *escapade* for a mature matron of 46. In this wedlock, she gave birth to a son. M. de Rocca survived her only a few months. On the whole, she had scantly been happy, as cursed with the 'desires infinite and hopes impossible' which make life little better than a sad unfulfilled longing to many of her peculiar temperament and genius. Her touching wail of '*Jamais, jamais, je ne serai jamais aimé comme j'aime*' was a cry out of her inmost heart. In this light, there may perhaps seem some element of pathos in this marriage, which looks otherwise a little ridiculous.

Madame de S.—all just deduction from her claims being made—must be ranked in the first class of female genius. Without question of her real power and originality, in the combination she presents of such a force of intellect as women have but rarely exhibited, with depth and tenderness of sentiment seeking its natural outlet in a rich and impassioned rhetoric, she may curtly, yet with clearness sufficient, be defined as a sort of Rousseau in petticoats.

Her son published an edition of her works in 18 vols. in 1821, with a biographical notice by Madame Necker de Saussure. See Norris, *Life and Times of Madame de S.* (1853).

STAFF, in Music, the name given to the five parallel lines and four intermediate spaces on which the characters indicating musical sounds are placed, the degrees of the staff indicating differences of pitch.

STAFF, in a Military sense, consists of a body of skilled officers, whose duty it is to combine and give vitality to the movements and mechanical action of the several regiments and drilled bodies composing the force. The distinction between an officer on the staff of an army and a regimental officer is that the latter is concerned with his own regiment alone, while the former deals with his army, or section of an army exceeding a regiment, and regulates the combined action of the several arms and bodies of men. A good staff is all-important to the success of a military enterprise.

The *General Staff* of an army comprises the general in actual command, with the subordinate generals commanding the several divisions and brigades; as assistants to these, the officers of the adjutant-general's department—i. e., the adjutant-general, his deputy, assistants, and deputy-assistants, if the army be large enough to require all. Similarly the officers of the quartermaster-general's department; the brigade-major; the provost-marshal; and the judge-advocate; and the controller (at the head of the civil departments); the functions of all of whom are described under their respective heads. The head of the general staff of the British army is at present a field-marshal commanding-in-chief, whose headquarters are at the War Office, of which department he is an *ex officio* member. He is responsible for the discipline of the army, and is assisted by the general officers in command of the military districts in England and Scotland, the semi-independent commander-in-chief in Ireland, and the commanders-in-chief in the various foreign possessions and colonies. India forms a nearly independent command, under a commander-in-chief, whose headquarters are in Bengal. There are subordinate commanders-in-chief in Bombay and Madras; and in each presidency there are

several military divisions. A certain period of military service, and certain qualifications, are required in an officer before he can be appointed to the general staff, and a proportion of the posts is given to officers who have passed the Staff College. The fact of having passed through it, however, is not held to constitute any claim to a staff appointment.

The *Personal Staff* consists of the aides-de-camp and military secretaries to the respective general officers. These officers are appointed, within certain limits, by the generals whom they serve.

The *Garrison Staff* consists of the officers governing in fortresses and garrisons; as Commandants (q. v.), Fort-majors (q. v.), Town-majors (q. v.), Fort-adjutants (q. v.), and Garrison-adjutants.

The *Civil or Departmental Staff* includes those non-combatants officers who have to provide for the daily requirements of the troops. These are the commissaries for supplies and stores, chaplains, medical and veterinary departments. These departments are described under their several names.

The *Recruiting Staff* consists of an inspector-general (at the War Office), and of the officers of the several brigade depots. The *Pensioner Staff* includes only the staff-officers of the enrolled force. The *Regimental Staff* includes the colonel, lieutenant-colonel, adjutant, paymaster, quarter-master, inspector of musketry, and medical officers. See RECRUITING, PENSIONERS, REGIMENT.

In the French and most continental armies, the staff is divided into the *état-major*, or general staff and the *intendance*, under an *intendant-général*, which comprises all the civil departments. There is a regimental staff in addition. The want of concentration of the civil departments often felt in the British service, led to the creation, in 1869, of the Control Department, subsequently split into two branches, the Commissariat (q. v.) and the Ordnance Store Departments. See INTENDANT.

In the Navy, the staff of a fleet consists of the Flag-officers (q. v.), the Flag-lieutenants (q. v.), and Secretaries (q. v.); also of the inspector-general of hospitals (see MEDICAL DEPARTMENT, NAVY), and an inspector of machinery.

STA'FFA, a celebrated islet on the west of Scotland, lies about 7 miles off the west coast of Mull. It forms an uneven tableland, rising at its highest to 144 feet above the water, 1¼ miles in circumference, and oval in shape. In the north-east, in the lee of the prevailing winds, is a tract of low shore, stretching out in beeches, and forming a landing-place. The other parts of the coast are girt with cliffs of from 84 to 112 feet high. Regarded in section, the rocks show themselves to be of three kinds—conglomerated tufa forming the basement; columnar basalt, arranged in colonnades, which form the façades and the walls of the chief caves; and amorphous basalt, overlying the columnar basalt, but pierced here and there by the ends of columns and by angular blocks. The most remarkable feature of the island is Fingal's or the Great Cave, the entrance to which is formed by columnar ranges on each side, supporting a lofty arch. The entrance is 33 feet wide, and 60 feet high, and the length of the cave is 212 feet. The floor of this marvelous chamber is the sea, which throws up flashing and many-colored lights against the pendent columns, whitened with calcareous stalagmite, which form the roof, and against the pillared walls of the cave.

STAFF COLLEGE is a government institution founded in 1858, about two miles from Sandhurst, for the purpose of giving higher instruction to 30 (increased in 1870 to 40) officers aspiring to appointments on the staff. It thus took the place, though more effectively, of the old senior class at the Royal Military College. To be entitled to compete for entrance, an officer must have been five years in active service, must have passed the qualifying examination for a captaincy, and must have the recommendation of his commanding officer. A very serious examination decides which among the competitors shall be admitted to the college, one only being eligible from any battalion. While at college, the students receive their regimental pay, and the whole educational charges (about £8000 annually) are borne by the public. The course lasts two years. At the end of each year, there is an examination, not competitive. After passing the Staff College, the officer is attached for duty, for a short period, to each of the arms with which he may not have already served. He then becomes eligible for appointment to the staff as opportunity may occur.

STAFF CORPS. During the wars of Wellington, the generals and staff officers were aided by a staff corps composed of intelligent officers and men who performed camp duties, made reconnoissances, and executed other necessary labors for which regimental officers or soldiers were unsuited. This corps died out after the peace. After the Crimean war, there were three staff corps—the Commissariat Staff Corps, Army Hospital Corps, and Military Store Staff Corps—which consisted of artificers, laborers, and orderlies, to aid in the work of their respective departments—as butchers, wardmasters, armorers, copyists, &c. The first and last were merged in 1870 into the Army Service Corps. S. C. is also the name given to the English Officers serving on the permanent Indian establishment.

STA'FFORD, an inland county of England, between the counties of Cheshire and Warwick, has an area of 732,434 acres, and a pop. of (1871) 858,326; (1881) 981,385. The most elevated portion of the county is the north, where wild moorlands in long ridges, separated by deeply cut valleys, extend from north-west to south-east, and subside as they near the valley of the Trent. The surface is low or undulating in the midland regions, but becomes hilly again in the south. New red sandstone occupies the whole of the central parts; the Pottery coal-field occupies the north, and the Dudley coal-field, remarkable also for its abundant and rich iron ores, occupies the south. The Trent, flowing first south-west through the county, then north-east along its eastern border, is the chief river. The climate is cold and humid, and though three-fourths of the area are arable, much of the soil is cold and clayey, and agriculture is in a backward condition. The Potteries lie around Stoke (q. v.), Burslem, and Hanley, and here most extensive manufactures of china and earthenware are carried on. See POTTERY and WEDGWOOD. In the south, iron is very largely manufactured in all its branches, from mining to the production of articles in iron and steel. The numerous canals (including the Grand Trunk Canal) and railways which intersect and traverse the county, afford abundant and most useful means of conveyance. The county of S. returns six members to the House of Commons.

STAFFORD, the county town of Staffordshire, stands on the Sow, 25 miles north-north-west of Birmingham. The usual municipal institutions of county towns are the chief buildings, and there are two fine and partly ancient parochial churches. Tanning, cutlery, and the manufacture of shoes are the chief branches of industry. S. sends two members to the House of Commons. Pop. (1881) 19,901.

STAG, a name familiarly given to a person who applies for an allocation of shares in a joint-stock concern, with a view of selling the allocation letter to another party for a small consideration. When no such consideration or premium is obtainable, the *stag* does not pay the deposit, which by his application he had become bound to do, and relinquishes any further interest in the undertaking. Persons acting thus, however, are liable to prosecution and exposure as defaulters. During the great railway mania of 1846, the stock-market was thronged with stags.

STAG, or RED DEER (*Cervus elaphus*), a species of Deer (q. v.) with round antlers, which have a snag at the base in front. The female has no horns, and is called a *Hind*. The young male, during the first year, acquires mere knobs in place of horns. In

Stag, Hind, and Calf (*Cervus elaphus*).

the second year, they are longer and pointed, when the animal is called a *Brocket*. The branching of the horns increases every year till the sixth, when the name Hart (q. v.) begins to be applied. After this, the age is no longer indicated by an increased number of branches, but the antlers become larger and thicker, their furrows deeper, and the *burr* at the base more projecting. The oldest stags have seldom more than ten or twelve branches, although an instance has occurred of 33 on each antler. A fine S. is four feet or more in height at the shoulder. The color is reddish brown in summer, the rump pale; in winter, it is brownish gray. The female is smaller than the male. The young is at first spotted with white. The S. is a native of Europe and the north of Asia. It was anciently common in all parts of Britain, but is now almost extinct, except in the Highlands of Scotland, where large herds still exist, particularly on the Grampians, and the sport of deer-stalking is pursued, in which the rifle is now

generally used; although, in former times, the S. was hunted, hounds of a peculiar breed, called Staghounds (q. v.), being employed for the purpose.

The forest laws of England were extremely strict for the preservation of this noble game, the unauthorized killing of a S. being even a more unpardonable offence than the killing of a man. The S. feeds on the buds and young shoots of trees, and on grass; or, in the severe weather of winter, on bark and mosses. The speed of the S. is very great. It has also great powers of swimming, and has been known to swim ten miles. When hard pressed by hunters, it turns to bay, and is not approached without danger. At the pairing season, which is in August, even tame stags become so excited that it is not safe to approach them. The domestication of the S. is never very complete. In fighting, the S. uses not only its horns, but its forefeet, with which it gives severe blows to an adversary. The flesh of the S. is not so good as that of the Fallow Deer.—Among the species of deer most nearly allied to the S. are the Wapiti (q. v.), an American species, and several species belonging to the warmer parts of Asia and the north of Africa. They all have round branched antlers, with a basal snag in front, and a tuft of hair on the hind legs, above the middle of the metatarsus.

STAG BEETLE (*Lucanus*), a genus of coleopterous insects, of the family *Lamellicornes*, remarkable for the large projecting mandibles of the males, which have large denticulations, and somewhat resembles stags' horns. The antennæ terminate in a club composed of many leaflets, disposed on an axis like the teeth of a comb. The COMMON S. B. (*L. cervus*) is one of the largest of

Stag Beetle (*Lucanus cervus*).

British insects, the males being fully two inches long. It flies about in the evening in the middle of summer, chiefly frequenting oak-woods. The larva feeds on the wood of the oak and willow, and is injurious to the trunks of trees, into which it eats its way very rapidly. It is supposed to be the *Cossus* of the ancient Romans, much esteemed by them as a delicacy. It lives for several years before undergoing its transformations. In its perfect state, the S. B. is a formidable-looking insect, and its powerful mandibles are capable of inflicting a pretty severe bite, if it is incautiously seized, but it is not venomous. Some of the tropical stag beetles are remarkable for their brilliancy of color.

STAG-HOUND, a large and powerful kind of Hound (q. v.), formerly much used in England for hunting the stag, but now almost

Staghound.

extinct. It is supposed to be a breed of the old English Southern Hound. In scent, it is almost equal to the bloodhound; in fleetness it is inferior to the foxhound. It has great power of endurance, and has been known to run 50 miles after the stag. It is also courageous, and does not hesitate to attack the stag when at bay.

STAGE. See THEATER.

STA'GGERS is a popular term applied to several diseases of horses. Mad or Sleepy Staggers is inflammation of the brain, a rare but fatal complaint, marked by high fever, a staggering gait, violent convulsive struggling, usually terminating in stupor; and treated by bleeding, full doses of physic, and cold applied to the head. Grass or Stomach Staggers is acute indigestion, usually occasioned by overloading the stomach and bowels with tough hard grass, vetches, or clover, a full meal of wheat, or other indigestible food. It is most common in summer and autumn, is indicated by impaired appetite, distended abdomen, dull aspect, unsteady gait; and is remedied by full doses of purgative medicine, such as six drachms of aloes and a drachm of calomel rubbed down together, and given in a quart of thin well-boiled gruel. Frequent clysters, with hand-rubbing and hot water to the belly, are likewise useful. Where the dullness increases, stimulants should be freely given. See HYDATIDS.

STAHL, GEORG ERNST, a celebrated German physician and chemist, was born at Anspach, 21st October 1660, studied medicine at Jena, and after practising successfully for some time, was called, in 1694, to the chair of Medicine, Anatomy, and Chemistry, in the newly-founded university of Halle; whence he removed to Berlin in 1716, where he was appointed physician to the king of Prussia. He was a member of the Berlin Academy, and died in that city 14th May 1734. According to Blumenbach, S. is to be considered as one of the greatest and most profound physicians the world has ever seen, though the mysticism with which his works are imbued is to be reprehended. S.'s system of medicine, which was a combination of the physiology of Van Helmont (q. v.) with the psychology of Descartes, is founded upon the supposition of the existence of a mysterious force residing in, but independent of, and superior to matter; this force, the *anima* (or 'soul'), not only forms the body, but directs it in the exercise of all its functions, and this, too, sometimes unconsciously; though the way in which this influence is exercised he does not explain. Being subject to error by nature, the 'anima,' by negligence or maladroit action, originates diseases in the body, which it then attempts to cure, through the functional action of the various parts. S. held that art ought only to commence where nature had ended, and to be useful, it should follow a similar course of action; he was also of opinion that plethora, either local or general, was one of the chief causes of disease. His system of therapeutics corresponded with his pathological principles, and was confined mostly to bleeding and the use of mild laxatives. His psychological theory of the connection between the soul and body led him into a discussion with Leibnitz (who had falsely charged him with propounding materialism), from which he emerged victorious on the essential points of their respective theories; though Leibnitz had the advantage in matters of detail.

Subsequent physiologists have made S.'s opinions the object of ridicule, though his doctrine of the 'anima' is, under the name of 'vital principle' and 'nature,' generally adopted at the present day; but his supercilious contempt for chemistry as a medical agent has long ceased to be generally upheld. Nevertheless, S. was one of the ablest chemists of his time, destroyed in his usual trenchant style, numberless absurd opinions which had found their way into the science, and propounded the first theory of combustion (see PHLOGISTON), which was universally accepted till the time of Lavoisier (q. v). His works, according to Haller, number 250, but the chief are—*Theoria Medica vera* (Halle, 1707, 1708, 1737), which contains his medical theory, and *Zymotechnia Fundamentalis, seu Fermentationis Theoria Generalis* (Halle, 1697), in which his chemical opinions are set forth. An account of his opinions is found in Haller's *Bibliotheca Medicinæ Practicæ*, vol. iii.; Sprengel's *Histoire de la Médecine;* A. Lemoine's *le Vitalisme et l'Animisme de Stahl* (Paris, 1864).

STAINED GLASS. See GLASS.

STAINS FOR WOOD. A variety of stains have recently been invented for the purpose of giving to the cheaper kinds of wood, such as deal, &c., the appearance of the more costly kinds. These are chiefly solutions of certain metallic salts, combined with vegetable infusions.

STAIR, EARLS OF. See DALRYMPLE.

STAI'RCASE. This feature, now so important in all houses, was of small note till about the time of Queen Elizabeth. Previously, stairs were all constructed on a circular plan, revolving round a central axis or newel, and were called turret or corkscrew stairs. During the 16th and 17th centuries, staircases with wide straight flights were first introduced, and were made leading features in the mansions of the Elizabethan style. They had usually massive oak balusters with carved pedestals, and were ornamented with carved panels, pendants, &c. Staircases of this description are still in common use, but are lighter in style, light cast-iron railings being substituted for the heavy oak balustrades.

STAKE NETS. See SALMON.

STALA'CTITES AND STALAGMITES are found in caves and other places where water charged with carbonate of lime is subject to evaporation. Water impregnated with carbonic acid is able to dissolve lime, and as all rain and surface water contains more or less carbonic acid, it takes up in its passage through the earth to the roofs of caves a certain amount of lime. When the water is exposed on the roof or floor of the cave, evaporation takes place, and so both the bulk of the water and its solvent power are reduced, and a thin pellicle of solid carbonate of lime is deposited. When this takes place on the roof of the cave, long icicle-like pendants are formed, which are called stalactites; and when the water drops upon the floor, a stalagmitic layer is formed, which rises at the points where the largest supply of material exists, in the form of pillars to meet the overhanging stalactites. In some caves, the descending and ascending points have met, and formed a series of natural columns as if supporting the roof. The color of the limestone thus formed is affected by the superincumbent strata, but it is generally white or yellowish. The stalactites have a rich subcrystalline structure, being composed of acicular radiating crystals, arranged in concentric layers from their exogenous growth. Sometimes, from metamorphic changes that have taken place subsequent to their formation, they become more truly crystalline. The amount of the deposition is very great in some caves, and the wonderful variety and singular groupings of the stalactites give them a peculiar beauty. The caves most remarkable in this way are the Cave of Adelsberg in Styria, the Grotto of Antiparos in the Grecian Archipelago, Wyver's Cave in the United States, and the caves of the Peak in Derbyshire.

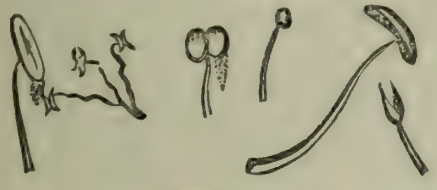
The remains of primeval man found in the caves in France, and the fossils from the bone caves in Britain and elsewhere, are generally cemented together into a stalagmitic deposit on the floor of the cave.

STALL, a fixed seat enclosed at back, and with elbows at the sides. One or more rows of these extended along each side of the choir of most churches before the Reformation, and fine examples still remain in nearly all the cathedrals. They are generally enclosed at back with a high screen, and covered with canopies ornamented with pinnacles, &c.

STA'LYBRIDGE, a market-town and parliamentary and municipal borough, partly in Lancashire and partly in Cheshire, stands on the Tame, eight miles east of Manchester. It is remarkable chiefly for its cotton manufactures. The print-works, iron-foundries, and machine-shops are also numerous and important. Free communication by railway is afforded in every direction. There are in S. 39 mills employing 10,000 hands, and 28 foundries and machine-shops, employing 1100 hands. Pop. (1871) of mun. borough, 21,092; (1881) 22,784.

STAMBOU'L. See CONSTANTINOPLE.

STA'MENS are those parts in the flowers of phanerogamous plants which excite the pistil to the formation of the fruit, and thus effect fertilization of Fecundation (q. v.), A stamen consists of a receptacle—the *anther;* which contains a dust—the *pollen*—various in color, but generally yellow, and is generally supported on a stalk called the *filament;* the anther being the blade of a metamorphosed leaf, and the filament the leaf-stalk. The filament is, however, sometimes awanting, and the anther is then said to



Stamens.

be *sessile*. Each anther generally consists of two cells forming two lobes, which, before they open to give forth the pollen, are again divided into two cell-like parts, and at the time of their maturity open by longitudinal clefts, by pores, or by valves, to scatter the pollen, which is conveyed to the stigma either by its own falling, by the wind, or by the insects which seek honey in flowers. See PISTIL. The pollen consists of single cells, which are usually free; more rarely, the pollen of each cell is united into a mass, called the *pollen-mass* or *pollinium*, as in the *Orchideæ* and *Asclepiadaceæ*. The stamens are either found along with the pistil in the same flower, and are then arranged around it, in which case the flower is *hermaphrodite;* or they are placed by themselves in separate flowers, which are therefore called *male* flowers.

The stamens are sometimes united together, generally by the filaments, which form a tube, and the flower is *monadelphous;* sometimes, by their union, they form two sets, when the flower is *diadelphous;* sometimes three or more, when it is *polyadelphous;* and the filaments are sometimes united with the pistil into a column, from which the anthers spring, as if they grew from the pistil, when the flower is *gynandrous*. See BOTANY. The stamens form either one or more whorls, and when in one whorl are either opposite to the petals or alternate with them. The latter is regarded as their normal position. Sometimes, by abortion, there is only one stamen. Being leaf-organs, stamens arise from the axis; but they very frequently grow upon the corolla, so that they seem to derive their origin from it. When the stamens seem to arise from the corolla or from the calyx, they, and also the flower are said to be *perigynous* (Gr. *peri*, around, and *gyne*, a wife); when they grow from the pistil, they are *epigynous* (Gr. *epi*, upon); and when from beneath it, *hypogynous* (Gr. *hypo*, under). These distinctions have been much made use of, by Jussieu and others, in classification. The transition of petals into stamens can be easily traced in some flowers, for example, in the Water Lily. In double flowers, the stamens have been changed into petals. Linnæus adopted the stamens as the means of his division of plants into classes (see BOTANY); but in so far as the classification was founded on their mere number, it was artificial, the number of stamens being various in plants very closely allied. Stamens are among the organs of plants which most frequently display Irritability (q. v.).

The filament assumes a great variety of forms. Sometimes it is short and thick, sometimes long and slender; sometimes dilated at the base; sometimes petal-like, with the stamen at its tip; sometimes forked, or divided into three teeth, of which the central one bears the anther; sometimes bent or jointed, sometimes spiral. The form of the anther varies still more than that of the filament; indeed, the variety of forms is endless. The *connective* is a body which unites the lobes of the anther. When the filament is continuous with the connective, the anther-lobes seeming to be united to it through their whole length, the anther is said to be *adnate* or *adherent;* when the filament ends at the base of the anther, the anther is *innate* or *erect*. In many flowers, as in those of grasses, the anther is attached to the filament by a mere point, and is very movable, easily turned by the wind. It is then said to be *versatile*.

STA'MFORD, an ancient market-town and a parliamentary and municipal borough of Lincoln, on the Welland, which is navigable hence to the sea, 11 miles north-west of Peterborough. Agriculture is almost the exclusive pursuit of the inhabitants of the district around, and S. is chiefly remarkable for its ancient remains. It first appears in history in 449, when the Britons and Saxons here defeated the Picts and Scots. Many of the Jews of S. were slain, and the whole community plundered in 1190 by those who had enlisted for the Crusade. In the middle ages several parliaments and councils were held here, and the town contained about 16 churches, and a number of religious houses. In 1572, a number of Flemish Protestant refugees settled here, and introduced the weaving of silk and serge. Portions of the walls and gates of the Carmelite and Franciscan priories, as well as other curious remains, are still extant. There are numerous schools and other important institutions. Pop. (1871) 8086; (1881) 8995. S. returns a member to the House of Commons.

STAMFORD, a town of Connecticut, U. S,, at the entrance of Mill River into Long Island Sound, 36 m. N.-E. of New York, on the New York and New Haven and New Canaan and Stamford Railways. It is a favorite residence and summer resort of opulent New Yorkers. It has 2 banks, 2 newspapers, 14 churches, a small coasting-trade, and manufactures of iron, boots and shoes, dye-stuffs, carriages, coal oil, &c. Pop. (1870) 9714; (1880) 11,297.

STA'MMERING AND DEFECTIVE SPEECH. Stammering is an affection of the vocal and enunciative organs, causing a hesitancy and difficulty of utterance, and respecting the nature and the origin of which a variety of different opinions has been entertained. Stammerers themselves often attribute the varying conditions of their impediment to causes which must be purely imaginary, such as the state of the wind, the changes of the moon, &c. There can be no doubt that the impediment is aggravated by depression of spirits, derangement of the digestive organs, physical debility, &c.; but these influences have nothing to do with the primary cause of the infirmity. A nervous dread of speaking is usually associated with stammering; but this is rather the result than the cause of the impediment. If constitutional nervousness were productive of stammering, the number of sufferers would be vastly greater, and it would include a larger proportion of females than of males; whereas the robust sex furnishes by far the greater number of cases; and it is noticeable, besides, that stammerers are not in general persons of weak nerves, otherwise than in connection with the act of speaking. Any physical defect will render a person nervous when the peculiarity is made a subject of observation, and it is in this way only that nervousness is associated with speech in cases of stammering. The strength of this impediment lies in *habit*, in mismanagement of the breath and the organs of utterance, rendered habitual before the development of reason and observation; and the removal

of the defect depends on the acquirement of voluntary control over the mechanical agents of speech. The nervousness which unfits the stammerer for self-direction gradually subsides as his will attains a mastery over the processes of speech; and perseverance in a discipline of systematic and guarded utterance rarely fails to remove the impediment, and the fear which accompanied it.

The first manifestations of stammering usually take place during the weakness attendant on disease, or after a fall or sudden fright; but sometimes the impediment appears to arise from imitation, and children have been known to be infected by even the most casual example. Thus, when one member or visitor of a family stammers, the younger members of the family are very apt to be similarly affected. From this cause defects of speech run so much in families, that many persons have thought them to be hereditarily transmitted. This, however, is altogether a mistake. In the early stages, a little patient direction on the part of parents and nurses would suffice to check the tendency to stammer, and prevent the formation of the unfortunate habit.

Stammering generally begins about the fourth or fifth year of age; but harshness in checking children, or impatience in connection with messages or lessons, may induce the impediment at a considerably later period. Boys of ten or eleven years of age have been excited into the habit by injudicious hurry and peremptoriness at school. The little stammerer, when he cannot be more directly assisted, should be kindly counselled to take time and speak slowly, and he should by no means be ridiculed or reproved for what he cannot help, and is not taught how to avoid.

The varieties of stammering are so great, that scarcely two cases are found precisely alike. In some there is but little outward manifestation of effort; in others, the futile attempts are painfully demonstrative. The silent straining to speak causes the eyeballs to protude, and the veins of the face and neck to swell, till relief from apparent choking comes in fitful ungovernable bursts of sound. In almost all cases the head oscillates loosely on the neck, and is forced upwards by the misdirected current of breath; while the larynx, the organ of sound, is from the same cause agitated in continual efforts to ascend, and the voice is consequently abrupt and intermittent, and unnaturally acute. The muscles of the face participate in the general upward action, and sometimes the spasmodic contortions extend over the whole body, causing the stammerer to rock in his chair, or start wildly to his feet. These muscular disturbances arise simply from disordered respiration, and they disappear when the habit of closing the glottis and compressing the organs of articulation is overcome and the air is allowed to pass freely in or out of the lungs.

The terms stuttering and stammering are often used synonymously, but the former term is properly, or, at least, conveniently, limited to a loose and imperfect action of the organs of articulation, as distinguished from the irregularity of breathing and the convulsive and choking symptoms which invariably accompany stammering. In stuttering, the organs meet and rebound again and again in reiteration of syllables before words can be fully formed. The source of this difficulty lies mainly in the lower jaw. When this organ is brought under control, and the effort of speech is transferred from the mouth to the throat—where all voice is formed—the power of fluency is readily obtained. But stuttering is rarely unaccompanied by some degree of spasmodic stammering, and the two forms of impediment, while theoretically distinct, are generally blended in mutual aggravation.

Stammering is, in nearly every case, perfectly curable, as it seldom arises from organic defect. The means of cure must, however, often be continued for a length of time before the stammerer is free from the danger of relapse. The best time for the cure is undoubtedly the earliest, before the habit has acquired full strength, and before the sufferer has endured the most grievous mortifications and drawbacks of the impediment. But the adult stammerer generally brings to the curative task a higher appreciation of its importance, and a greater care and concentration of effort than the child is capable of; and these qualities almost compensate for the disadvantage of long-established habit. Parents often unwisely defer the attempt to correct impediments of speech, in the hope that the defects will disappear as the child gains strength and reaches riper years. But the hope is very rarely realized; and were it otherwise, the misery of years of impediment, and the hindrance to education which stammering certainly involves, are evils to be avoided by all possible means. With this, as with all habits, 'prevention is better than cure;' and stammering would be easily and certainly prevented by timely advice carried out with ordinary care in the nursery.

The means that have been proposed for the cure of stammering have been as various as the theories of the nature of the defect; and sometimes the 'cure' has been apparently but little better than the disease. Drawling, singing, interpolations or elisions of letters, speaking with the teeth closed, or with the tongue pressed to the roof of the mouth, sniffling, whistling between words, beating time to utterance, stamping the foot, jerking the body, forks on the tongue, pebbles in the mouth, or tubes fixed between the organs, bands compressing the larynx, and other absurd and uncouth devices, have been under cover of expedient secrecy, practised on unhappy stammerers. But the removal of this defect, as above shown, depends on the skilful application of scientific principles, respecting which there is no mystery save that which arises from the little attention that has been paid to the science of speech.

From the preceding account of the nature of stammering, it is almost superfluous to add that the cure of this impediment does not fall within the province of surgery. Yet the barbarous operation of cutting a wedge from the root of the tongue—introduced from Germany about 25 years ago—and the equally futile and cruel operation of excising the tonsils, have been, within no distant date, extensively practised by surgeons in this country.

The habit of stammering can only be counteracted by the cultivation of a habit of correct speaking; and the latter can only be acquired by studying the processes of speech, the relation of breath to articulate sounds, the positions of the tongue and the other oral organs in moulding the outward stream of air; and by a patient application of these principles in slow and watchful exercise. The lungs constitute a pair of bellows, and the mouth, in all its varying shapes, the nozzle of the bellows. The passage of the throat must be kept open, and the breath expelled by means of the ascent of the diaphragm, not by downward pressure of the chest. All sound originates in the throat, and all effort in speech must be thrown back behind the articulating organs, which must be kept *passive*, yielding to the air, always opening to give it exit, and never resisting it by ascent of the tongue or of the jaw. The head must be held firmly on the neck, to give free play to the attached organs; and the great principle must never be lost sight of that *speech is breath;* and that, while distinctness depends on precision and sharpness of the oral actions *fluency* depends on the unrestrained emission of the material of speech—the air we breathe.

Besides stammering and stuttering, there are many other forms of vicious articulation, which are rather defects than impediments of speech. The elementary sounds most subject to mispronunciation are those of *r* and *s*, giving rise to the common defects of burring and lisping. Burring consists in vibrating the uvula or the edge of the soft palate, instead of the tip of the tongue; and lisping consists in applying the tongue to the teeth or the gum, so as to intercept the breath, and force it over the sides instead of the center of the tongue. The sound of *l* also is often defective, *w*, *y*, *ng*, or a *vowel* being substituted for the lingual articulation. Other substitutions of one element for another are common, such as *t*, *d*, and *n*, for *k*, *g*, and *ng; s* or *z* for *th; s* for *sh*, &c. There are also defects which arise from organic malformation, and require the aid of surgery; as when fissure exists in the palate, and the breath cannot be enclosed behind the lips or tongue, but escapes into the nostrils; when the tongue is too closely tied to the bed of the mouth, and the tip cannot be raised to the palate; when the teeth are so irregular or abnormally numerous as to leave the tongue too little room to act, &c. In some cases the breath escapes into the nostrils when there is no organic cause for the peculiarity, and *r*, *l*, *s*, and other elements are nasally affected, merely from habit. The nasal passages are, in other cases, insufficiently free, and *m*, *n*, and *ng* are scarcely distinguishable from *b*, *d*, and *g*.

There are comparatively few persons who have perfect command over their vocal organs. Speaking, which is in reality an art, is exercised only as an instinct; and thus, as an eminent American author (Dr. Rush) observes, 'some men only bleat, bark, whinny, or bray a little better than others.' It is some consolation to those who have been compelled by defects to study the art of speech, that they exercise the crowning faculty of man's nature more worthily than others, and thus become, perhaps, better speakers than they would have been without the stimulus of defect or impediment.

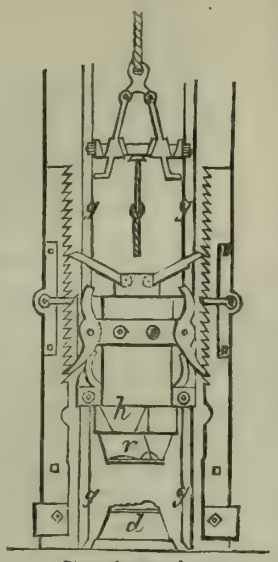
Speaking, when the respiration is properly conducted, is one of the most healthful exercises; but violent or long-continued effort is injurious to the chest, when the lungs are not kept well inflated. Frequently, also, under such circumstances, the vocal chords become permanently relaxed, and total loss of voice sometimes ensues.

The acquirement of the power of speaking in infancy is dependent on the possession of hearing, so that deaf children are also mute. Under proper training, however, they may be taught to articulate, as the organs of speech are very rarely imperfect. Children who have been subject to fits or other cerebral affections, or who are deficient in imitative power, are sometimes very backward in learning to speak. In such cases, great care is requisite to direct the early attempts, and prevent the formation of bad habits. Many of the worst forms of defect and impediment owe their origin simply to the want of proper direction in the production of elementary sounds, when the little sufferers have failed to enounce them correctly by natural imitation.

It is unnecessary to enumerate the various English, American, and foreign authors who have propounded conflicting theories of

the cause, and schemes for the cure of impediments of speech. Of the systems practised in this country at the present day, those of Dr. Hunt and Mr. Melville Bell have been most fully published. The views of these authors differ but little, and are in substance the same as those contained in this article.

STAMPING OF METALS. There are different kinds of stamping. The plan adopted for producing coins or medals is described under MINT, and the preparation of the dies used, under DIE-SINKING. For the ordinary stamped brass-work, so extensively made in Birmingham, a stamping-machine is employed, of which the essential parts are a *die*, a *reverse* or counter-die, and a *hammer*. It is shown in the annexed figure; but the toothed rack, with arrangement for catching the hammer after it rebounds, is only used for special purposes. The die *d*, which is made of cast iron or steel, is fixed to the bottom of the stamp, and the reverse, *r*, is attached to the hammer *h*, which works between two guides *g*, *g*, pieces of thin rolled brass are cut to size, and one placed upon the die; the hammer, with the counter-die, is now raised to a sufficient height by a windlass and rope, or other means, and allowed to fall, and thus force the thin plate into the die. The plates from the first blow are then annealed. Repeated blows and annealings follow until the article is 'brought up,' slight alterations in the reverse being from time to time required. Sometimes as many as 30 blows are necessery, but 10 or 12 strokes will suffice for an object with a considerable depth of raising. Globular articles are stamped in two or more pieces, and then soldered together.



Stamping-machine.

The stamping process was first adapted to the production of hollow shapes in sheet-iron by Mr. T. Griffiths, in 1841; and since then, the manufacture of such goods as dish-covers, basins, and teapots has been improved and extended to a surprising extent. In the case of a dish-cover, for example, a single sheet of iron is brought to the required shape by repeated stampings and burnishings upon a chuck. It is afterwards tinned with great ease, there being no joints to interfere with the operation; for the same reason, iron basins stamped out of a single sheet can be readily enamelled. The old way of forming these articles by hand-labor was very tedious and clumsy.

German silver is too brittle a metal to be stamped like brass or iron, consequently it has only hitherto been made into small objects, such as spoons and forks by this process. But the Messrs. Elkington of Birmingham are now making articles of considerable size in this material, by means of a stamping-press worked by hydraulic power. A number of graduated dies are used for one object, each pair coming gradually nearer the desired shape, but none of them making an impression deep enough to strain the metal.

For stamping-machines used in dressing metallic ores, see METALLURGY.

STAMPS, or STAMP DUTIES, are taxes imposed on all parchment and paper whereupon private deeds or other instruments of almost any nature are written. It is a convenient mode of raising the public revenue, and was first instituted by a statute of 5 and 6 Will. and Mary, c. 21. The subsequent statutes are varied and complicated, and embrace nearly every kind of legal document.

STA'NCHIONS, or STANCHELS, upright iron bars fixed in the stonework to protect windows. They are sometimes let into the stone at top and bottom; sometimes at bottom only, and ornamented with fleurs-de-lis, &c., at top.

STA'NDARD. In its widest sense, a standard is a flag or ensign under which men are united together for some common purpose. The use of the standard as a rallying-point in battle takes us back to remote ages. The Jewish army was marshalled with the aid of standards belonging to the four tribes of Judah, Reuben, Ephraim, and Dan, and the Egyptians had ensigns with representations of their favorite animals. The flag of Persia was white, and, according to Xenophon, bore in his time a golden eagle with expanded wings; it was fixed on a chariot, and thus conveyed to the field of battle. Æschylus, in enumerating the six chiefs who headed by Polynices, set themselves in battle array against Thebes, describes the device on the standard of each.

In the earliest era of Roman history, a bundle of hay or fern is said to have been used as a military standard, which was succeeded by bronze or silver figures of animals attached to a staff, of which Pliny enumerates five—the eagle, the wolf, the minotaur, the horse, and the boar. In the second consulship of Marius, 104 B.C., the other animals were laid aside, and only the eagle retained; and down to the time of the later emperors, the eagle, often with a representation of the emperor's head beneath it, continued to be carried with the legion. On the top of the staff was often a figure of Victory or Mars. Each cohort had also an ensign of its own, consisting of a serpent or dragon woven on a square piece of cloth, and elevated on a gilt staff with a cross-bar. Under the Christian emperors, the *Labarum* (q. v.) was substituted for the imperial standard. Various standards of great celebrity occur in medieval history, among which may be enumerated the Flag of the Prophet (q. v.); the standard taken from the Danes by Alfred of England; and the Oriflamme, originally belonging to the Abbey of St. Denis, and borne by the Counts of Vexin, which eventually became the standard of the French kingdom.

In strict language, the term standard is applied exclusively to a particular kind of flag, long in proportion to its depth, tapering towards the fly, and, except when belonging to princes of the blood-royal, slit at the end. Each baron, knight, or other commander in feudal times, had a recognized standard, which was distributed among his followers. The length of the standard varied according to the rank of the bearer. A king's standard was from 8 to 9 yards in length; a duke's, 7 yards; a marquis's, 6½ yards; an earl's, 6 yards; a viscount's, 5½ yards; a baron's 5 yards; a banneret's, 4½ yards; and a knight's 4 yards. There was never a complete coat-of-arms on the standard; it generally exhibited the crest or supporter with a device or badge of the owner, and every English standard of the Tudor era had the cross of St. George at the head. Standards were registered by the heralds, and the charges on them selected and authorized by an officer of arms.

The so-called Royal Standard of Great Britain is more properly a Banner (q. v.), being a square flag with the national arms covering the entire field without any external accessories. The so-called cavalry standards in use in the British army are also in strictness banners. They are small in size; their color is determined by the color of the regimental facings, and they are charged with the cipher, number, insignia, and honors of the regiment. The banners of the household troops are, however, all crimson and richly embroidered with the royal insignia of England. Corresponding to the standards of the cavalry are the colors of the infantry regiments, of which each has 'a pair,' one, called the Queen's color, being the Union Jack (q. v.), charged with some ornamental device; the other, the regimental color, with the cipher, number, device, motto, and honors of the corps, cantoned with a small union jack. When a regiment obtains new colors, they are usually given by the wife of the colonel, or some lady of distinction.

STANDARD, BATTLE OF THE, a battle between the English and Scots which took place on Cutton Moor, near Northallerton, when the latter were defeated with great loss. On the usurpation of Stephen, David I. of Scotland, who, along with Stephen, had sworn to defend the rights of Matilda, daughter of Henry I., invaded England in pursuance of his oath, and compelled the barons of the northern part of the kingdom to swear fealty to that princess. After a war of nearly three years' duration, David encountered the English troops at Cutton Moor, on 22d August 1138, with a large but undisciplined army, who, partly in consequence of a rumor that the king was slain, were thrown into confusion, and the most disastrous route followed, in which the Scots are said to have lost 10,000 men. The battle derived its name from the circumstance that a ship's mast, bearing on its summit the consecrated host, and surrounded by the banners of St. Peter of York, St. John of Beverley, and St. Wilfred of Ripon, elevated on a wagon, marked the center of the English army.

STANDARDS. In Carpentry, the quarters or upright posts in wooden partitions are so called. The upright timbers to which doors are hung are called door standards.

STANDING ORDERS is the name given to those permanent regulations which may be made by either House of Parliament for the conduct of its proceedings, and are binding on the House by which they are made as continual by-laws enduring from parliament to parliament unless rescinded. A standing order of the House of Lords, when rescinded, is said to be *vacated*; in the Commons the corresponding term is *repealed*. In the Lords, a motion for making or dispensing with a standing order cannot be granted on the same day that the motion is made, or till the House has been summoned to consider it; and every standing order, as soon as agreed to, is added to the 'Roll of Standing Orders,' which is carefully preserved and published from time to time. In the House of Commons there was, until 1854, no authorized collection of standing orders, except such as related to private bills. In that year a manual of rules, orders, and forms of proceeding relative to public business was drawn up and printed by order of the House.

Standing orders are occasionally suspended when it is desirable that a bill should be passed with unusual expedition.

STANDING STONES. Large rude unhewn blocks of stone, artificially raised to an erect position at some remote period, have been found in almost every part of the world where man has fixed his habitation. We find them in Britain, in continental Europe, in Assyria, India, Persia, and even in Mexico, and they are generally of such a size that their erection presupposes some degree of skill in the use of mechanical power. They are especially abundant in the British Isles, where they sometimes stand singly, and sometimes in more or less regular groups; and it was long the general opinion of archæologists that they were connected with the Druidical worship of the Celtic races. The result of modern investigation has been to throw doubts on the Druidical theory, while no other explanation has been given which is in all cases satisfactory. The erection of a large stone not easily shifted from its place is perhaps the earliest mode which man's instinct would contrive of preserving the memory of an event or of a hero; and there can be no doubt that many of these monoliths mark the site of a grave or of a battlefield. Human skeletons, and bronze and iron weapons, have been in numerous cases found underneath them. A traditional remembrance of this origin is preserved in the name of 'Cat Stane' (from Celtic *cath*, battle), given to some of them in Scotland, and 'bauta stein' (battle stone) in Norway. Another possible purpose is preserved in the Scotish name of 'hair stane,' or boundary stone, by which they are occasionally known; not a few of them, whatever their original object, having been long used as landmarks, and being alluded to as such in very early charters. A third use of these monoliths is at least as old as the historical books of the Old Testament.

We read in Judges ix. 6, of Abimelech being made king 'by the pillar which was in Shechem,' and in 2 Kings xi. 14, of Joash, when he was anointed king, standing 'by a pillar, as the manner was;' and a like usage prevailed in ancient Britain, where the king or chief was elected at the 'Tanist stone' (from *Tanist*, the heir-apparent among the Celts), and there took a solemn oath to protect and lead his people. A very celebrated stone of this kind was the Lia Fail of Ireland, which was brought to Icolmkill for the coronation of Fergus Ere; and after being removed to Scone, became the coronation stone of Scotland, till conveyed away by Edward I. to Westminster, where it now forms part of the coronation chair of the sovereigns of the United Kingdom. In all these cases there is an idea of a solemn religious sanction attached to the stone; and a peculiar degree of sacredness seems to have invested any contract entered into at one of those perforated stones which are or were occasionally to be met with in England and Scotland. Such a stone, with an oval hole large enough to admit a man's head till lately adjoined the monolithic group of Stennis in Orkney. It was known as the 'Stone of Odin,' and continued till the middle of last century to be the scene of the interchange of matrimonial and other vows, he who broke the vow of Odin being accounted infamous. It is said to have been the popular belief that any one who had in childhood been passed through the opening would never die of palsy. The power of curing rheumatism was ascribed to a perforated stone at Madderty in Cornwall. While many of the monoliths in Britain are undoubtedly of a very remote age, there are some indications that the practice of erecting them continued for a time after the introduction of Christianity, and that they were used to subserve purposes connected with the new faith. A series of monoliths in the island of Mull are traditionally said to have been guide-posts to pilgrims visiting Iona, and it has been suggested that they point out the route which St. Columba must have pursued on his way to the residence of the Pictish king, Brude Mac Meilochon.

Still more puzzling to archæologists than the single monoliths are the large symmetrical groups of them, of which the most remarkable are Stennis in Orkney, Stonehenge and Avebury in Wiltshire, and Carnac in Brittany; all which, till lately, existed comparatively entire, though they have all been in the memory of the present generation more or less despoiled for building purposes. The most imposing of these monuments is Stonehenge (q. v.). At Stennis, from 70 to 80 stones were grouped in two separate circles of 360 and 100 feet diameter respectively, the largest stones being in the smaller circle. At Avebury, two double concentric circles were surrounded by an outer circle of 100 stones, the whole being approached by two long avenues of stones in double lines. In all these, and other instances, the circles were surrounded by a trench and mound. At Carnac the stones are placed not in circles but in straight lines, with a curved row at one end—an arrangement which has suggested the idea of a burial-place on the site of a great battle-field. All around Carnac, as well as Stonehenge, Barrows and Cromlechs (q. v.) are to be found. While the popular notion of all these monuments is that they were Druid temples, the circular form so frequent among them has also suggested that they may originally have been connected with sun-worship, and it is not impossible that they may have been used in turn for the successive religious worship of different races. They seem also to have served the purpose of courts of justice, or battle-rings for the duel and judicial combat See STONEHENGE.

Standing Stones of Stennis.

A remarkable description of monument, whose purpose is utterly unknown to us, is the *Rocking-stone* or *Logan-stone* (q. v.). For a notice of a class of standing stones of considerable interest, ornamented with a peculiar description of sculpture, and found largely in Scotland, see SCULPTURED STONES.

STANFIELD, CLARKSON, a distinguished painter, was born of Irish parents, in the town of Sunderland, about the year 1793. At an early period of his life, he went to sea, and made frequent long voyages, among which was that to China. In the China seas, he passed some years of his life, and served for a time in the same ship with Douglas Jerrold; S. in the capacity of a common sailor, and Jerrold as a midshipman. While thus engaged, S. exhibited considerable talent both in painting and drawing. The first person of public note, however, to observe S.'s genius as a painter was the celebrated Captain Marryat, who met with him in the Mediterranean, serving in a king's ship as captain's clerk. S. and Marryat afterwards became intimate; and in 1840 the novelist employed the painter, then become famous, to illustrate his *Poor Jack*. S. left the navy, in consequence of an injury to his feet, through a fall from the fore-topgallant mast-head of his ship. He then took to scene-painting as a means of earning his bread. His first efforts in this direction were made in the Old Royalty Theater, Wells Street, Wellclose Square, in the east end of London, about the year 1818. He was afterwards employed at Drury Lane Theater, and here it is said that he produced some of his most extraordinary effects. He carried on this occupation until the year 1827, when he finally abandoned it, except on rare occasions. S., while painting for the theaters, had by no means neglected easel-painting. The first picture by him that attracted any considerable notice was 'Market-boats on the Scheldt,' exhibited at the British Institution in 1826. The picturesque grouping, variety of figures, and gay costumes were much admired. His 'Wreckers off Fort Rouge, Calais,' exhibited in the following year, also at the British Institution was even more successful. In 1828, he obtained from the British Institution a prize of fifty guineas for another of his pictures.

In 1830, S. made his first excursion on the continent, and in the same year exhibited at the Academy his 'Mount St. Michael, Cornwall,' which placed him at once in the foremost rank as a marine painter. In 1823, S., in conjunction with David Roberts and others, founded the Society of British Artists. His election to the Academy as Associate took place in 1832; and in 1835 he was chosen R.A., in conjunction with Sir William Allan. In 1833, S. exhibited at the Academy the first of a series of pictures of Italian scenery, painted for the Marquis of Lansdowne for the banqueting-room at Bowater. In 1834, he commenced a similar series for the Duke of Sutherland. In 1836, he exhibited 'The Battle of Trafalgar,' painted for the Senior United Service Club; and in 1841, his celebrated 'Castello d'Ischia,' engraved by the Art-union in 1844. In 1843, he sent to the Academy 'Mazerbo and Lucello, Gulf of Venice,' said to be one of the finest landscapes he ever painted. 'A Skirmish off Heligoland' (1867) was S.'s last contribution to the exhibitions of the Academy, of which he was so distinguished a member. His great merit lies in the skilful combination of land and sea in the same view. Man and the works of man are not disdained by him in his portraiture of nature, and there is frequently a poetic feeling of the highest order in some of his conceptions, as in his pictures of 'The Abandoned,' and 'The Wreck of a Dutch East Indiaman.' S. died on the 18th of May 1867.

STANHOPE, LADY HESTER LUCY, the eldest daughter of Charles, third Earl Stanhope, and his wife Hester, daughter of the great Lord Chatham, was born on the 12th March 1776. She grew up to be a woman of great personal charm, and of unusual force and originality of character Very early she went to reside

with her uncle, William Pitt, and as mistress of his establishment, and his most trusted confidant during his season of power, and till his death, she had full scope for the exercise of her imperious and queenly instincts. On the death of Pitt, a pension of £1200 a year was assigned her by the king. Mr. Fox proposed to provide for her much more munificently, but she proudly declined his offers, as unwilling to accept benefit at the hands of the political enemy of her dead uncle.

The change from the excitements of a public career, as it might almost be called, to the life of an ordinary woman of her rank with means somewhat insufficient, was naturally irksome to her, and in 1808, she was tried still further by the death, at Coruña, of her favorite brother Major Stanhope, and of Sir John Moore, for whom she is known to have cherished an affection. The precise relations between them have never been made known; but the last words spoken by the dying hero were: 'Stanhope' (a Captain Stanhope of his staff, who stood by him), 'remember me to your sister.' Conceiving a disgust for society, she retired for a time into Wales, and in 1810, she left England never to return to it. In mere restlessness of spirit she wandered for a year or two on the shores of the Mediterranean, and finally settled herself among the semi-savage tribes of Mount Lebanon. Here she led the strangest life, adopting in everything the Eastern manners, and by the force and fearlessness of her character, obtaining a curious ascendency over the rude races around her. She was regarded by them with superstitious reverence as a sort of prophetess, and gradually came so to consider herself. With the garb of a Mohammedan chieftain, she adopted something of the faith of one, and her religion, which seems to have been sincere, and profound, was compounded in about equal proportions out of the Koran and the Bible. Her recklessly profuse liberalities involved her in constant straits for money; and her health also giving way, her last years were passed in wretchedness of various kinds, under which, however, her untamable spirit supported her bravely to the end. She died in June 1839, with no Frank or European near her, and was buried in her own garden. The main sources of information about her are the notes of the frequent travelers who visited her in her strange seclusion, and the *Memoirs* derived from her own lips, and afterwards (3 vols. Lond. 1845—1846) published by a medical gentleman who went abroad with her, and from time to time lived with her in her retirement.

STANHOPE, PHILIP HENRY, EARL, historian and biographer, was representative of a branch of the family of the Stanhopes, Earls of Chesterfield. Its founder, a distinguished diplomatist in the reigns of William III. and Queen Anne, was son of the first Earl of Chesterfield. James, first Earl Stanhope, was an eminent military commander, who effected the reduction of Port Mahon, in the island of Minorca, and was the favorite minister of George I. His grandson, the third earl, distinguished for his scientific researches, and inventor of a printing-press which bears his name, died 1816. The subject of this notice, only son of the fourth earl, was born at Walmar, 1805. His courtesy title was Viscount Mahon. He received a private education, but graduated at Oxford, where he took his B.A. degree, 1827; created D.C.L., 1834. He entered the House of Commons in 1830. He was greatly instrumental in 1842 in securing the passing of the Copyright Act (q. v.); was Under-secretary for Foreign Affairs during the brief Peel administration, 1834—1835; and Secretary to the Indian Board of Control under the same minister, 1845—1846. He was a moderate Conservative in politics, and was warmly attached to Sir R. Peel, who named him one of his literary executors. His contributions to history are numerous and valuable. Macaulay, in a review of one of his earliest works, the *War of the Succession in Spain*, accredits him with some of the most valuable qualities of a historian, viz., perspicuousness, conciseness, 'great diligence in examining authorities, great judgment in weighing testimony, and great impartiality in estimating characters.'

His most considerable work is *A History of England from the Peace of Utrecht to the Peace of Versailles*, 1713—1783, in 7 vols. His other works include a *Life of the Right Hon. W. Pitt;* a *History of Spain under Charles II.;* a *Life of the Great Condé;* a *Life of Belisarius;* a volume of *Historical and Critical Essays;* and a volume of *Miscellanies*. Of the *Life of Condé*, it may be remarked that it was originally written by the author in the French language, and that the English work is really a translation, executed under his superintendence. In conjunction with the Right Hon. E. Cardwell, he edited the *Memoirs of Sir R. Peel;* and he also published an edition of *Lord Chesterfield's Letters*. He was elected President of the Society of Antiquaries, 1846; Lord Rector of the university of Aberdeen, 1858. He was mainly instrumental in procuring the appointment of the Historical Manuscripts Commission. He was elected one of the six foreign members of the Academy of Moral and Political Sciences at Paris in 1872. His death took place at Bournemouth on Dec. 24, 1875.

STANISLA'WOW, or STANISLAU, a town in the Austrian crownland of Galicia, pleasantly situated between two branches of the Bistricza, 75 miles south-east of Lemberg. It is the seat of active trade and manufactures. Pop. (1880) 18,626.

STANLEY, HENRY M., American journalist and explorer of Africa, was born in 1841. The place of his birth has been matter of dispute. He became notable as special correspondent of the *New York Herald*, and in that capacity traveled in various parts of the world, accompanying for example the English expeditions to Abyssinia and Ashantee. But it was as the 'discoverer of Livingstone' that S. suddenly obtained a world-wide reputation. Commissioned by the proprietor of his newspaper, S. started from Zanzibar in April, 1871, and succeeded in meeting Livingstone at Ujiji on Nov. 10—what an expedition equipped by English 'Livingstone Relief Committees' had failed to accomplish. On his arrival in England in July, 1872, S. was received with universal acclamation; but by his subsequent exploration of the lake region of equatorial Africa and of the Lualaba-Congo (see CONGO) in 1874–7 he has placed himself in the front rank of African travelers. Under a joint commission from the *New York Herald* and the London *Daily Telegraph*, S. started from the east coast of Africa in 1874, circumnavigated the Victoria N'yanza, marched across country to the Albert N'yanza, and then coming south again, examined part of Tanganyika and its outlet towards the Lualaba. From Unyanyembe he pushed onwards along the course of the Lualaba, supported by a large party of followers; and arriving at the mouth of the Congo in Aug. 1877, he proved that the Congo (q. v.) and Lualaba were identical. In 1879, he became a leader of the Belgian International Society's expedition for establishing commercial and civilizing stations on the Congo. Of S.'s works, *How I found Livingstone* appeared in 1872; *My Kalulu*, in 1872; *Coomassie and Magdala*, in 1874; *Through the Dark Continent*, in 1878.

STANLEY, THE RIGHT HON. EDWARD HENRY SMITH, now Earl of Derby, an eminent English statesman, eldest son of the fourteenth Earl of Derby (q. v.), was born at the family seat, Knowsley Park, Lancashire, July 21, 1826, was educated at Rugby, and at Trinity College, Cambridge, where he concluded a distinguished university career by taking a first-class in classics in 1848, together with a declamation prize and mathematical honors. He early adopted the profession of statesmanship, and especially applied himself to the study of social and economical questions. During his absence on a tour in Canada, the United States and the West Indies, he was elected (December 1848) M.P. for King's Lynn, on the death of Lord G. Bentinck. He afterwards visited the East, and was still in India when his father received the Queen's commands to form an administration, in which S. was appointed Under-secretary for Foreign Affairs. In 1855, on the death of Sir W. Molesworth, Lord Palmerston paid him the compliment of offering him the seals of the Colonial Office. The offer was declined; but in 1858 he was appointed to the Secretaryship of the Colonies in Lord Derby's administration, and was soon called upon to succeed the Earl of Ellenborough (q. v.) as President of the Board of Control for the affairs of India. The great Indian mutiny had not yet been quelled, and it devolved upon S. to frame resolutions and bring in a bill abolishing the East India Company (q. v.), and transferring their Indian possessions to the direct government of the crown. This duty he performed with consummate ability. The great mutiny was put down during his secretaryship, and in February 1859 he had to meet the legacy of financial disorganization which it bequeathed.

The Derby government resigned before S. could carry out his plans for establishing the finances of India on a sounder basis, but he gave effective support to his successor in office, in reducing the military expenditure, and other measures of administrative improvement. In his father's third administration, formed in July 1866, he was invested with the office of Secretary of State for Foreign Affairs, and the ability and tact he displayed in conducting the negotiations for the settlement of the Luxemburg difficulty, obtained for him a considerable amount of popularity. He continued in this office till the accession of the Gladstone Ministry to power in 1868. In April 1869, he was installed Lord Rector of the university of Glasgow, and in October of the same year, on the death of his father, he took his seat in the House of Lords. He was again made Foreign Secretary by Mr. Disraeli in 1874; but on account of divergence from the views of the Premier on the Eastern Question, he, like his colleague the Earl of Carnarvon, retired from the Ministry early in 1878; and in 1882 he became Secretary of State for the Colonies in Mr. Gladstone's Liberal administration. In 1874, he was elected Lord Rector of Edinburgh University. His speeches are remarkable for admirable good sense.

STANLEY, THE VERY REV. ARTHUR PENRHYN, D.D., an eminent scholar and divine of the Church of England, was the son of the late Edward Stanley, D.D., Bishop of Norwich, and nephew of the late Lord Stanley of Alderley. He was born 13th December 1815, while his father was rector of Alderley, and resided there. Educated at Rugby under the care of Dr. Arnold,

he passed (1834) as an Exhibitioner to Balliol College, Oxford, where he achieved a brilliant reputation, winning the Ireland Scholarship, and taking a first class in classics (1837) the Latin essay prize (1839), and the English essay and theological prizes (1840). In 1838 he was chosen a Fellow of University College, of which he was tutor and examiner for many years. Appointed Canon of Canterbury (1851), Professor of Ecclesiastical History at Oxford, Canon of Christ Church, and Chaplain to the Bishop of London (1858), he succeeded Archbishop Trench in 1864 as Dean of Westminster. He was also chaplain to the Queen. In 1874 he was elected Rector of St. Andrews University. His wife, a daughter of the Earl of Elgin, died in 1876. He died 18th July 1881, and was buried in the Abbey he loved so well. S., one of the most liberal theologians of this age, was for great part of his life leader of the 'Broad Church' party; in virtue of his literary genius, varied accomplishments, and sympathetic and generous piety, he ranks among the most eminent of recent Christian teachers. His principal writings, besides his contributions to reviews and to Smith's classical dictionaries, are the *Life of Dr. Arnold* (1844); *Sermons and Essays on the Apostolical Age* (1846); *Memoir of Bishop Stanley* (1850); *The Epistles to the Corinthians* (1854); *Sinai and Palestine* (1855); *The Unity of Evangelical and Apostolical Teaching* (1859); *Lectures on the Eastern Church* (1861); *Lectures on the Jewish Church* (1863—1865 and 1876); *Sermons preached before the University of Oxford* (1860—1863); *Historical Memorials of Westminster Abbey* (1867); *The Three Irish Churches* (2d ed., 1869); *Essays on Church and State* (1870); *The Athanasian Creed* (1871); *Lectures on the Church of Scotland* (1872); a work on the Utrecht Psalter (1874); *Christian Institutions; Essays on Ecclesiastical Subjects* (1881).

STA'NNARIES (Lat. *stannum*, tin), the mines from which tin is dug. The term is most generally used with reference to the peculiar laws and usages of the tin mines in the counties of Cornwall and Devon. By an early usage peculiar to these counties, the prerogative of the crown, elsewhere reaching only to gold and silver mines, is extended to mines of tin, which are the property of the sovereign, whoever be the owner of the soil. A charter of King John to his tinners in Cornwall and Devonshire, of date 1201, authorized them to dig tin, and turf to melt the tin, anywhere in the moors, and in the fees of bishops, abbots, and earls, as they had been used and accustomed—a privilege afterwards confirmed by successive monarchs. When Edward III. created his son, the Black Prince, Duke of Cornwall, he at the same time conferred on him the Stannaries of Devon and Cornwall, which were incorporated in perpetuity with the duchy. Their administration is committed to an officer called the Lord Warden of the Stannaries, who has two substitutes or vice-wardens, one for Cornwall, and one for Devon. In former times, representative assemblies of the tinners (called parliaments) were summoned by the warden under a writ from the Duke of Cornwall, for the regulation of the stannaries and redress of grievances: the last of them was held in 1752. The Stannary Courts are courts of record held by the warden and vice-warden, of the same limited and exclusive character as the Courts-palatine, in which the tinners have the privilege of suing and being sued. They were remodelled and regulated by acts 6 and 7 Will IV. c. 106, 2 and 3 Vict. c. 58, and 18 and 19 Vict. c. 32. The last-mentioned statute provides, that from all the decrees and orders of the vice-warden on the common law side, there shall be an appeal to the Lord Warden, who is to be assisted by two assessors, members of the Judicial Committee of the Privy Council, or judges of the High Court of Chancery, or Court of Common Law at Westminster; and from the Lord Warden there is a final appeal to the Judicial Committee of the Privy Council.

In the county of Cornwall, the right to dig tin in unenclosed or 'wastrel' lands within specified bounds may be acquired by one who is not the owner of the lands, on going through certain formalities, the party acquiring this right being bound to pay one-fifteenth to the owner of the lands. An ancient privilege, by which the Duke of Cornwall had the right of pre-emption of tin throughout that county, has long fallen into abeyance; and certain duties to which he was entitled on the stamping or coinage of tin were abolished by 1 and 2 Vict. c. 120.

STA'NNIC ACID. See TIN.

STANOVOI', or STANOWOI KHREBET (Framework Mountains), an extensive mountain chain in Siberia, in the extreme north-east of Asia, forms the watershed between the rivers which flow north into the Arctic Ocean, and those which are tributary to the Amur. The chain extends in an east-north-east direction from the Transbaikal territory along the shores of the Sea of Okhotsk, separating into several branches, one of which stretches east to Behring's Strait. Of this great mountain chain, the length of which is estimated at 3000 miles, little is known further than that it is elevated and rugged, and that its peaks are covered with perpetual snow.

STA'NZA. See RHIME.

STAPE'LIA. See CARRION FLOWERS.

STAPHYLE'A AND STAPHYLEA'CEÆ. See BLADDERNUT.

STAPHYLO'MA (from the corresponding Greek word, derived from *staphyle*, a bunch of grapes, or in this case, rather a grape at the end of a stalk) is a term employed by the oculist to signify any protrusion on the anterior surface of the eye. Staphyloma of the iris occurs when there is a protrusion of the iris through a perforation of the cornea, consequent either on ulceration or on a wound. Staphyloma of the cornea occurs when that coat of the eye is more or less completely destroyed, and when the cicatrix with which the iris has become covered is caused to protrude by the pressure of the fluids of the eye, in the form of an opaque white prominence. It is unnecessary to enter into details of the treatment of these affections, which must be left entirely to the hands of the surgeon.

STAPLE (A.-S. *stapel*, a prop, support; a heap, and hence a place where goods are stored up or exposed for sale), a term applied, in the commerce of the middle ages, in the first instance, to the towns in which the chief products of a country were sold, and afterwards to the merchandise that was sold at the staple towns. The staple towns, at first chosen from convenience, came in the course of time to be invested with important privileges. The staple merchandise of England has been enumerated as wool, woolfells (i. e., sheepskins), leather, lead, and tin, to which have sometimes been added butter, cheese, and cloth. *Wool* was, however, in point of fact, a far more important article of export than any of the rest, and was really the subject of those multitudinous regulations which fixed the staple in particular towns, both of England and of the continent. Goods intended for exportation had, in the first instance, to be exposed for sale at the staple town; the principal purpose of this regulation being, probably, to restrict commerce to those places where the officers who collected the king's customs could superintend it. Another object kept in view in the provisions made in the 13th and 14th centuries with respect to the staple, was the encouragement of the resort of foreign merchants; indeed, greater privileges seem to have been accorded to the foreign than to the English merchants who attended the staple.

A tribunal of great antiquity, called the Court of the Staple, had cognizance of all questions which should arise between merchants, native or foreign. It was composed of an officer, called the Mayor of the Staple, re-elected yearly by the native and foreign merchants who attended the staple; two constables, appointed for life, also chosen by the merchants; a German and an Italian merchant; and six mediators between buyers and sellers, of whom two were English, two German, and two Lombard. The law administered was the *lex mercatoria*, and there was a provision that causes in which one party was a foreigner, should be tried by a jury one half of whom were foreigners. The most important legislative enactments regarding the Staple and the Court of Staple were the Statute of Acton Burnel (11 Edward I.), by which merchants were enabled to sell the chattles of their debtor, and attach his person for debt; 13 Edw. I. c. 3; and 27 Edw. III. c. 2, called the Statute of Staple, one object of which was to remove the staple formerly held at Calais to certain towns in England, Wales, and Ireland. With the growth of commerce the staples became more and more neglected, and at last fell altogether into disuse.

STAR, in Heraldry. The star is of frequent occurrence as a heraldic bearing; it sometimes represents the heavenly body so called, and sometimes the rowel of a spur. In the latter case, it

Stars.

is blazoned a *Mullet* (q. v.). Stars of more than five points should have the number of points designated, and the points may be wavy. A star, or *estoile*, with wavy points, is often designated a blazing star; and when the points are more than six in number, it is usual to represent only every second point as waved.

The star is a well-known ensign of knightly rank. A star of some specified form constitutes part of the insignia of every order of knighthood.

STAR, ORDER OF THE, an order of knighthood formerly existing in France, founded by John II. in 1350, in imitation of the then recently instituted order of the Garter in England. The ceremony of installation was originally performed on the festival of the Epiphany, and the name of the order is supposed to have been allusive to the Star of the Magi.

STARAI'A-RU'SSA, a town of Russia, in the government of Novgorod, 184 miles south-south-east of St. Petersburg. The town is remarkable for its salt springs, which attract many visitors in

summer. The means of communication between St. Petersburg and S., by the Moscow Railway and the river Volkhov, are easy and rapid. Resident pop. (1880) 14,750.

STAR ANISE. See ANISE.

STAR APPLE (*Chrysophyllum*), a genus of trees and shrubs of the natural order *Sapotaceæ*. The species are natives of tropical and subtropical countries. The S. A. of the West Indies (*C. Cainito*) is a shrub about eight or ten feet high. The fruit is large, rose-colored, mixed with green and yellow; and has a soft sweet pulp of an agreeable flavor. Other species produce edible fruit.

STA'RBOARD. See LARBOARD.

STARCH, or AMYLACEOUS MATTER ($C_{12}H_{10}O_{10}$), is an organized substance of the class known as carbo-hydrates, which occurs in roundish or oval grains in the cellular tissue of certain parts of plants. It is very widely diffused through the vegetable kingdom, and is especially abundant in the seeds of the cereals, in the seeds of leguminous plants such as peas and beans, in the tuber of the potato, in the roots of arrowroot and tapioca, in the pith of the sago palm, &c. The grains of starch from the same kind of plant are tolerably uniform in size and shape, but vary in different species of plants from $\frac{1}{180}$th to less than $\frac{1}{300}$th of an inch in diameter; and while some are circular or oval, others are angular: moreover, amongst other differences, some (chiefly the larger grains) exhibit a series of concentric rings, while in others no rings are apparent; and while the grains of potato-starch, if illuminated by polarized light, with a Nicol's prism placed between the object and the eye, present a well-marked black cross, in wheat-starch no such cross is perceptible.

Ordinary commercial starch occurs either as a white glistening powder, or in masses which are readily pulverized; and when pressed between the fingers it evolves a slight but peculiar sound. It is heavier than water, and is insoluble in cold water, alcohol, and ether. If, however, it be placed in water at a temperature of 150°, its granules swell from the absorption of fluid, and the mixture assumes a viscid, pasty consistence. Dilute acids rapidly induce a similar change, even without the agency of heat; and if heated with dilute sulphuric acid, the starch is first converted into dextrine, and finally into glycose or grape-sugar; and manufacturing chemists avail themselves of this property to obtain glycose on a large scale from starch. Starch dissolves in cold nitric acid, and on the addition of water to this solution, a white, tasteless, insoluble precipitate falls, which is known as *Xyloidin*, and explodes violently when struck by a hammer, or when heated up to about 350°. The composition of this substance is not positively known, but in all probability one or two equivalents of the hydrogen of the starch (most probably two) are replaced by a corresponding number of equivalents of peroxide of nitrogen (NO_4).

The reactions of starch with iodine and bromine are very remarkable. Iodine communicates to it a very beautiful purple color, and hence starch-paste serves as a delicate test for free iodine. The purple color which the iodine gives to the starch granules appears not to depend on a chemical combination, because on the application of heat the color disappears, and reappears on cooling. Bromine communicates a brilliant orange tint to starch—a reaction by which the presence of free bromine may be readily detected. When heated to a temperature of from 340° to 400°, dry starch is converted into Dextrine (q. v.), or British gum. At a higher temperature, it undergoes decomposition, and yields on dry distillation the same products as sugar. When heated in steam under pressure, it also passes into dextrine, and finally into glycose. The addition of a little sulphuric acid hastens these changes.

During the germination of seed, the starch undergoes a kind of fermentation, and is converted into a mixture of dextrine and glycose. This change is due to the action of a peculiar ferment termed Diastase (q. v.), which exists in all germinating seeds during the process of growth, and is probably a mixture of albumen and gluten in a special stage of decomposition. Various animal matters, as, for example, saliva, pancreatic juice, the serum of the blood, bile, &c., exert the same action on starch as diastase. On treating starch with chlorine, a remarkable, colorless, oily fluid *Chloral* (q. v.), is obtained. On prolonged exposure to the air, starch paste becomes acid, in consequence of the formation of lactic acid.

Starch is usually obtained by a simply mechanical separation of it from the other ingredients with which it is associated; advantage being taken of its insolubility in cold water. The details of the mode of separation vary according to the source from which it is procured. We extract from Miller's *Organic Chemistry* the method of procuring *potato-starch*: 'This variety is prepared on a large scale from potatoes, which contain about 20 per cent. of amylaceous matter. The cellular tissue of the tuber does not exceed 2 per cent. of the mass; whilst of the remainder about 76 per cent. consists of water, and the rest of small quantities of sugar, salts, and azotized matters. In order to extract the starch, the tubers are first freed from adhering earth by a thorough washing, and are then rasped by machinery. The pulp thus obtained is received upon a sieve, and is washed continuously by a gentle stream of water so long as the washings run through milky. This milkiness is due to the granules of starch which are held in suspension. The milky liquid is received into vats, in which the amylaceous matter is allowed to subside; the supernatant water is drawn off, and the deposit is repeatedly washed with fresh water until the washings are no longer colored. The starch is then suspended in a small portion of water, run through a fine sieve to keep back any portions of sand, and after having been again allowed to settle, is drained in baskets lined with ticking; the mass is then placed upon a porous floor of half-baked tiles, and dried in a current of air, which is at first of the natural temperature; the drying is completed by the application of a moderate artificial heat' (pp. 100, 101).

To obtain starch from wheat or rice, a more complicated process is required, as the large quantity of gluten which is associated with the starch in these grains requires to be removed either by fermentation, or, according to Jones's patent, by a weak alkaline solution, which dissolves the gluten, but does not affect the starch granules.

Commercially, there are two classes of starch—those used for food, and those used for manufacturing purposes. The former are treated under ARROW-ROOT (q. v.); the latter are chiefly made from wheat, rice, and potatoes; but in addition, large quantities of sago-starch are prepared in India and sent to Europe, and small quantities are from time to time prepared from other sources, such as the fruit of the horse-chestnut, &c.

The importance of starch becomes at once obvious when we consider that it may be regarded as the starting-point in the preparation of brandy and other forms of spirit, and of beer and porter, and that it enters largely into the great *saccharine* group, constituting one of the leading subdivisions of food. See DIGESTION. It is, moreover, largely employed as an article of domestic use for laundry purposes, and also in the manufacture of dextrine and grape-sugar.

We shall conclude with a few words on starch in its physiological and medical relations. It might have been inferred *a priori* that starch was an essential article of diet, from the fact of its abundant occurrence in edible vegetables, even if the fact had not been established by numerous physiological experiments. Thus various kinds of potatoes yield from 12 to 27 per cent. of starch; peas, 32½ per cent.; beans, 34 to 36 per cent.; wheaten bread, 53½ per cent.; wheaten flour, 56½ to 72 per cent.; oatmeal, 59 per cent.; ryemeal; 61 per cent.; barley-meal, 67 per cent.; maize, 81 per cent.; rice, 83 to 85 per cent.; and it occurs in even larger proportions in arrowroot, sago, and tapioca.

In a state of health, the proper diet consists in the due admixture of the albuminous saccharine (or starchy), oleaginous, and saline groups; but in certain forms of disease, an excess or a diminution of the starchy element is expedient. Thus, in cases of weak gastric digestion, it is not advisable to mix starchy food with the albuminous, as it soaks up the too scanty gastric juice without making any use of it. In such cases, moreover, articles of food like potatoes, new bread, pastry, &c., are apt to turn acid in the stomach, and check digestion. There are, again, some cases of gastric disorder in which a purely starchy diet is expedient. Thus, according to Dr. Chambers, it is the best form of food 'during acute catarrhal bilious attacks at the commencement of treatment, in even chronic gastric cases, and whenever a dusky complexion, hypochondriasis, or general distress show that arrested moulting has caused a collection in the body of effete tissues' (*Dietetics* in *Clinical Lectures*, 4th ed., p. 539). In the early stages of rheumatic fever and other acute diseases, it is usually expedient to limit the diet of the patient for a day or two to a purely starchy diet, such as arrowroot, tapioca, panado, &c. In returning from a purely starchy to a mixed diet, Dr. Chambers suggests that such an arrangement shall be adopted as to prevent starchy and albuminous foods from being together in the stomach. For example, let the morning and evening diet be vegetable, with a mid-day meal of purely animal food. It should be recollected that although starch is converted into sugar by the saliva, pancreatic fluid, and intestinal juice (see DIGESTION), the change principally takes place from the action of the two last-named fluids in the small intestine. Hence, when the duodenum, jejunum, or ileum are morbidly affected, as in typhoid or enteric fever, in enteritis, in diarrhœa, &c., little or no starch should be given in the food.

Wheat-starch is the only variety of starch admitted into the Pharmacopœia. It is employed in medicine chiefly in the form of mucilage (prepared by triturating 120 grains of starch with 10 fluid ounces of distilled water gradually added, and boiling for a few minutes, constantly stirring). This preparation is used either alone or as a vehicle for more active agents, as an enema, in dysentery, diarrhœa, flatulent distention of the bowels, &c.; externally, it is used as an application to excoriations, to prevent bedsores, &c., and as a basis for dusting-powders in various forms of

discharging skin-diseases. Its use in Surgery for the construction of immovable bandages has been noticed in the article SPLINTS.

STAR-CHAMBER, a tribunal of considerable note in English history, which met in the old Council-chamber of the palace of Westminster, and is said to have its name from the circumstance that the roof of that apartment was decorated with gilt stars. It is generally supposed to have originated in early times out of the exercise of jurisdiction by the king's council, acting as the *concilium ordinarium* and not *privatum*. The powers of the council, however, had been abridged by several acts of Edward III., and had altogether greatly declined when act 3 Henry VII. c. 1, either revived and remodelled them, or instituted, according to the view taken by Mr. Hallam, an entirely new tribunal. This statute conferred on the Chancellor, the Treasurer, and the Keeper of the Privy Seal, with the assistance of a bishop and a temporal Lord of the Council, and Chief-justices, or two other justices in their absence, a jurisdiction to punish, without a jury, the misdemeanors of sheriffs and juries, as well as riots and unlawful assemblies. Act 21 Henry VIII, c. 20, added to the other members of the court the President of the Council.

Whether or not the above-cited act of Henry VII. meant to constitute a court distinct from the council, it is certain that, by the time of Elizabeth, the two jurisdictions were merged in one; and the resulting tribunal was, during the Tudor age, of undoubted utility as a means of bringing to justice great and powerful offenders who would otherwise have had it in their power to set the law at defiance. The civil jurisdiction of the Star-chamber, at that period, comprised controversies between English and foreign merchants, testamentary causes, disputes between the heads and commonalty of corporations, lay and ecclesiastical, and claims to deodands. As a criminal court, it could inflict any punishment short of death, and had cognizance of forgery, perjury, riots, maintenance, fraud, libels, conspiracy, misconduct of judges and others connected with the administration of the law, and all offences against the state, in so far as they could be brought under the denomination of contempts of the king's authority. Even treason, murder, and felony could be brought under the jurisdiction of the Star-chamber, where the king chose to remit the capital sentence. The form of proceeding was by written information and interrogatories, except when the accused person confessed, in which case the information and proceedings were oral; and out of this exception grew one of the most flagrant abuses of this tribunal in the later period of its history. Régardless of the existing rule, that the confession must be free and unconstrained, pressure of every kind, including torture, was used to procure acknowledgments of guilt; admissions of the most immaterial facts were construed into confessions; and fine, imprisonment and mutilation inflicted on a mere oral proceeding, without hearing the accused, by a court consisting of the immediate representatives of prerogative. The proceedings of the Star-chamber had always been viewed with distrust by the commons; but during the reign of Charles I., its excesses reached a height that made it absolutely odious to the country at large; and in the last parliament of that sovereign, a bill was carried in both Houses (16 Car. I. c. 10), which decreed its abolition.

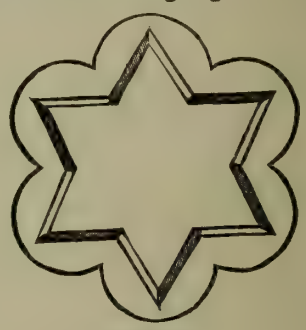
STAR-FISH (*Asteriadæ*), a family of *Echinodermata* (q. v.), having in the center of the body a stomach with only one aperture, but extending by two much-branched cæca, into each of the rays into which the body is divided. In some, the central disc extends so as to include the rays, so that the general form is angular or lobed; in others, the disc is very small in comparison with the length of the rays. Locomotion is effected by very numerous Ambulacra (q. v.) placed in rows on the under side of the rays. A bony framework, of a vast number of pieces, extends to the extremity of each ray. The nervous system has its center around the mouth, and sends a filament to each ray. Star-fishes are hermaphrodite, and produce vast numbers of eggs, which are retained for a time under the body of the parent, resting on the points of its rays at the bottom of the sea, and raising up the center of the body, in order as it were to hatch them. The young are destitute of rays, and very unlike the mature form, so that their real nature was long mistaken. The mouth of star-fishes being on the under side, they seek their food—as indeed they perform all their motions—by crawling at the bottom of the sea, or on rocks, &c. They are very voracious, and are troublesome to fishermen by devouring their bait. They possess, in a very high degree, the power of reproducing lost members; a disc with a single ray left will reproduce the other rays, and become a perfect star-fish. More extraordinary is the readiness which many of them display, particularly those with long and slender rays, in breaking off these members.

Some species—BRITTLE STARS—can scarcely be procured for a museum in a tolerably perfect state, because they throw off ray after ray, and, in fact, break themselves to pieces upon any alarm. Star-fishes abound in the seas of all parts of the world. Almost no object is more familiar on the sea-coast of Britain than the COMMON S., CROSS-FISH, or FIVE FINGERS (*Asterias* or *Uraster rubens*), thrown up on the beach by the tide, or thrown out of fishing-boats in harbors. Some of the species are much

Star-fishes:
1, Common Cross-fish (*Uraster rubens*); 2, Gibbous Starlet (*Asterina gibbosa*); 3, Common Cross-fish, reproducing rays; 4, Eyed Cribella (*Cribella oculata*); 5, Lesser Sand-star (*Ophiura albida*).—From Forbes's *British Star-fishes*.

larger; and some exhibit very beautiful colors; whilst others are interesting from their structure—the long serpent-like form of their rays, or the division of the rays by successive forkings, so that the whole creature is a globular mass, the surface of which is formed of a countless multitude of living tendrils.

STAR-FORT, in Field Fortification, is a strong work consisting of alternate salient and re-entering angles, arranged on a regular



Star-fort.

or irregular polygon. It is a common work for defending an eminence on a battle-field, or at the wing of a line, or as protection for the reserve-stores of an army.

STA'RGARD (Slav. *Starograd* or *Starigrod*, i. e., Old Town), a town of Germany, province of Pomerania, is situated on the navigable river Ihna, 23 miles east-south-east of Stettin, with which, as with Posen, and the whole east of Prussia, it is connected by railway. S. was formerly the capital of Lower Pomerania. It has various but not very important manufactures. Pop. (1880) 21,816. S. was raised to the rank of a town in 1129.

STAR JELLY. See NOSTOC.

STA'RLING (*Sturnus*), a Linnæan genus of birds, of the order *Insessores;* now the family *Sturnidæ;* nearly allied to *Corvidæ*, but in general of smaller size; the bill more slender and compressed, its point nail-like; the wings long and pointed. They are natives of almost all parts of the world, very generally gregarious, and some of them migratory. They feed on worms, insects, larvæ and fruits. Some of them follow herds of quadrupeds on account of the insects which attend them. The COMMON S. (*Sturnus vulgaris*) is a beautiful bird, rather smaller than the song-thrush or mavis, brown, finely glossed with black, with a pale tip to each feather, giving the bird a fine speckled appearance, particularly on the breast and shoulders; in advanced age it is more uniform in color. The plumage of the female is less beautiful than that of the male. Both sexes are more speckled in winter than in summer. The S. is abundant in most parts of Britain, and nowhere more so than in the Hebrides and Orkneys. It is very abundant in the fenny districts of England. It is found in all parts of Europe, and throughout great part of Africa; and is also common in the north of Asia. Starlings make artless nests of slender twigs, roots, and dry grass, in hollow trees, in holes of

cliffs, under eaves of houses, or, readily enough, in boxes, which are often placed for them in trees or elsewhere near houses. They frequently breed twice in a season, and in autumn they unite in large flocks. The S. becomes very pert and familiar in confinement, displays great imitative powers, and learns to whistle tunes, and even to articulate words with great distinctness. Its natural

Starling (*Sturnus vulgaris*).

song is soft and sweet.—The AMERICAN S., or MEADOW LARK (*S. Ludovicianus*), is larger than the Common Starling. It is common in the United States, migrating northwards in spring, and southwards in autumn, and congregating in great flocks in autumn and winter.

STARLINGS, in Architecture, are large piles driven in outside the foundations of the piers of bridges to break the force of the water and save the piers.

STAR-NOSE (*Condylura*, or *Astromyctes*), a genus of the Mole (q. v.) family, *Talpidæ* having much general resemblance to moles, but with a longer tail, and an elongated slender muzzle, which bears at its extremity a remarkable structure of fleshy and somewhat cartilaginous rays disposed in a star-like form. The habits are very similar to those of moles. All the species of this genus are natives of North America. The best known is *Condylura cristata*, which inhabits Canada and the eastern parts of the United States.

STARODOU'B, a town of European Russia, in the government of Tchernigov, and 100 miles north-east of the town of that name. It stands in the middle of a fertile district, but at a distance from any commercial highway. Pop. (1880) 16,820.

STAR OF BETHLEHEM (*Ornithogalum*), a genus of bulbous-rooted plants of the natural order *Liliaceæ*, nearly allied to Squills and Hyacinths. These species are pretty numerous, natives almost exclusively of the eastern hemisphere, many of them of the Cape of Good Hope, and some of the south of Europe. The Com-

Star of Bethlehem (*Ornithogalum umbellatum*).

mon Star of Bethlehem (*O. umbellatum*), a native of France, Switzerland, Germany, the Levant, &c., is very common in flower-gardens. Its flowers are large, six to nine, in a corymbose raceme, white and somewhat fragrant. *Gagea lutea*, formerly, *O. luteum*, with yellow flowers, is found in some parts of Britain in woods and pastures.

STAR OF INDIA, THE MOST EXALTED THE ORDER OF THE, an order of knighthood instituted by Queen Victoria in June 1861, with the view of affording the princes, chiefs, and people of the Indian Empire, a testimony of her Majesty's regard, commemorating her Majesty's resolution to take on herself the government of India, and rendering honor to merit and loyalty. The order consists of the Sovereign, a Grand-master, who is to be the Governor-general of India for the time being, and 25 knights, together with such extra and honorary knights as the crown may appoint. The members of the order are to be military, naval, and civil officers who have rendered important service to the Indian Empire, and such native chiefs and princes of India as have entitled themselves to her Majesty's favor. The insignia consists of a collar, badge, and star. The *collar* of the order is composed of the heraldic rose of England, two palm branches in saltire tied with a ribbon, and a lotus-flower alternating with each other, all of gold enamelled, and connected by a double golden chain. From an imperial crown, intervening between two lotus-leaves, depends the *badge*, consisting of a brilliant star of five points, and hanging from it an oval medallion, with an onyx cameo profile bust of Queen Victoria, encircled by the motto: 'Heaven's light our Guide,' in gold letters, on an enriched border of light-blue enamel. The *investment badge* is similar to the collar-badge, but

Star of India.

with the star, the setting of the cameo, and the motto all of diamonds: it is worn pendent from a ribbon of pale blue with white borders. The *star* of the order is a five-pointed star or mullet of diamonds on an irradiated field of gold. Around it, on an azure fillet bordered with gold, is the same motto in diamonds, the whole encircled by wavy rays of gold.

STARS are distinguished from planets by remaining apparently immovable with respect to one another, and hence they were early called fixed stars, a name which they still retain, although their perfect fixity has been completely disproved in numerous cases, and is no longer believed in regard to any. Twinkling, or Scintillation (q. v.), is another mark which distinguishes stars from planets.

The first thing that strikes the observer is the apparent daily motions of the stars. The greater part appear to rise in the east, describe smaller or greater arcs in the heavens, and set in the west; while others describe complete circles round a point north of the zenith, that described by the so-called polar star being the smallest visible to the naked eye. These apparent motions arise from the rotation of the earth on its axis. Had the earth only this rotatory motion, the aspect of the starry heavens at any spot on the earth's surface would be the same at the same hour of the night all the year round; which is known not to be the case. In consequence of the earth's motion round the sun, or the apparent advance of the sun among the stars, the aspect of the heavens at a particular hour is always changing. The same position of the stars recurs four minutes earlier each night, and only at the same time after the lapse of a year.

With few exceptions, the *distance* of the fixed stars is still unknown, and must in all be enormously great. Since the time of Bradley, many attempts have been made to measure what is called the *yearly parallax* of the stars, and thus determine their distances. When we consider that the motion of the earth round the sun brings us at one time a whole diameter of its orbit (184 millions of miles) nearer to a particular region of the heavens than we were six months before, we should expect a change in the relative distances of the stars as seen from the two points—that as we approach them they should seem to separate. But no such change is seen to take place; and this was one of the early objections to the theory of Copernicus. The only answer that the Copernicans could give was, that the distance of the stars from us is so great that the diameter of the earth's orbit is as a point compared with it. The detection of the parallax of the fixed stars depended upon the perfection of instruments.

The parallax of a star is the minute angle contained by two lines drawn from it, the one to the sun, the other to the earth. If that angle amounted to a second, the distance of the star would be 206,000 times that of the sun; and when the measurement of angles came to be reliable to a second, and still no parallax was discernible, astronomers could say that the distance of the nearest stars must be more than 206,000 times that of the sun—i. e., 206,000 times 92 millions of miles, or about 20 billions of miles. It is only since between 1832 and 1838 that anything like positive determinations of parallax have been made, chiefly by Henderson, Bessel, and Peters. The first published (Dec. 1838) was that of the double star 61 in the constellation of the Swan, by Bessel, who made the parallax 0″·37, giving a distance over 550,000 times that of the sun, or 52 billions of miles, so that the light of this star is about 8½ years in reaching the earth. The nearest of all the stars yet measured is *α Centauri*, the finest double star in the southern heavens, whose parallax was determined by Henderson and Maclear at the Cape of Good Hope to be 0″·9128 (the observations were made in 1832—1833; the result read before the Astronomical Society, Jan. 1839), or as subsequently corrected, 0″·976, corresponding to a distance of about 20 billions of miles, and requiring 3¼ years for its light to reach us. To Sirius, the brightest of the stars, a parallax of 0″·15, has been assigned, implying a distance six times that of α Centauri. 'It has been considered probable, from recondite investigations, that the average distance of a star of the *first* magnitude from the earth is 986,000 radii of our annual orbit, a distance which light would require 15½ years to traverse; and further, that the average distance of a star of the *sixth* magnitude (the smallest distinctly seen without a telescope) is 7,600,000 times the same unit—to traverse which, light, with its prodigious velocity, would occupy more than 120 years. If, then, the distances of the majority of stars visible to the naked eye are so enormously great, how are we to estimate our distance from those minute points of light discernible only in powerful telescopes? The conclusion is forced upon us that we do not see them as they appeared within a few years, or even during the lifetime of man, but with the rays which proceeded from them several thousands of years ago!'—Hind's *Astronomy*.

The stars have been divided into groups called Constellations (q. v.) from the earliest times. The several stars belonging to the same constellation are distinguished from one another by Greek letters, beginning the alphabet with the brightest; and when these are not sufficient, by Roman letters and by numbers. Many of the most brilliant stars have special names. They are also divided according to their brightness into stars of the first, second, third, &c., magnitudes—a division which is necessarily somewhat arbitrary. The smallest stars discernible by a naked eye of ordinary power are usually called stars of the fifth magnitude; but an unusually sharp eye can discern those of the sixth and even seventh magnitude. All below are *telescopic* stars, which are divided in a very undetermined way down to the twentieth magnitude. Sir J. Herschel has determined that the light of Sirius, the brightest of all the stars, is 324 times that of a mean star of the sixth magnitude. By processes of photometric observation and reasoning, it is concluded that the intrinsic splendor of α Centauri is more than twice that of our sun, and that of Sirius 394 times. Among stars of the first magnitude in the northern hemisphere are usually reckoned Aldebaran (in Taurus), Arcturus (in Bootes), Atair (in Aquila), Betelgeux (in Orion), Capella (in Auriga), Procyon (in Canis Minor), Regulus (in Leo), Vega (in Lyra). In the southern hemisphere are Achernes (in Eridanus), Antares (in Scorpio), Canopus (in Argo), Rigel (in Orion), Sirius (in Canis Major), Spica (in Virgo), and α Centauri and α Crucis that have no special names.

No apparent magnitude, in the proper sense of the word, has yet been observed in any star. In the best and most powerfully magnifying telescopes, even the brightest stars of the first magnitude, appear, not with small discs as all the planets do, but as luminous points without any visible diameter, and always the smaller the better the telescope. We are therefore totally ignorant of the real size of the fixed stars; nor could it be determined though we were sure of their distances, for the apparent diameter is an essential element in the calculation. We cannot, then, say whether the greater brilliancy of one star, when compared with another, arises from its greater nearness, its greater size, or the greater intensity of its light. It is certain that all the fixed stars are self-luminous. By the spectroscope several facts regarding their physical constitution have been made out; there are great differences in their spectra; the existence of several known elements is considered demonstrated. Sirius, e. g., contains hydrogen, sodium, and magnesium.

The *number* of the stars is beyond determination. Those visible by the naked eye amount only to a few thousands. Stars of the first magnitude are usually reckoned at 15—20, of the second at 50—60, of the third about 200, of the fourth at 400—500, of the fifth at 1100—1200. But in the following classes, the numbers increase rapidly, so that stars of the sixth and seventh class amount to above 12,000. Stars are most dense in that region of the heavens called the Milky Way, which is mostly composed of stars of the eleventh and twelfth magnitudes. W. Herschel observed 116,000 stars pass the field of his telescope in a quarter of an hour, while directed to the densest part of the Milky Way.

That the fixed stars are not really immovable, as their name would imply, is seen in the phenomenon of *Double* or *Multiple Stars* which are systems of two or more stars that revolve about one another, or rather about their common center of gravity. As they can be seen separate only by means of a telescope, and in most cases require a very powerful one, their discovery was possible only after the telescope was invented. Galileo himself discovered their existence, and proposed to make use of them in determining the yearly parallax of the fixed stars. After a long lapse of time, Bradley, Maskelyne, and Mayer again directed attention to the phenomena of double stars; but nothing important was made out respecting them till the elder Herschel made them the subject of a protracted series of observations, which led to the most remarkable conclusions as to their nature. The united observations of Struve, Savary, Encke, South, and especially those of Herschel the younger, continued for four years in the southern hemisphere at the Cape of Good Hope, have raised the number of observed double, or rather multiple, stars to more than 6000, of which the greater part are binary, or composed of two, but many are triple, some quadruple, and a few even quintuple, or consisting of five stars. The distance between the stars composing these systems is always apparently small (varying from less than 1″ up to 32″); but apparent nearness does not always constitute a double star, for two really distant stars are not unfrequently so nearly in the same line, as seen from the earth, that they appear to be close together. In real multiple stars, the individuals are not only comparatively near to one another, but they revolve around one another. Among stars of the first three magnitudes, every sixth is a multiple star; among the smaller stars, the proportion is much less. In some cases, one of the stars is much larger than the other, as in the star Rigel in Orion, and in the polar star; but oftener the connected stars are nearly equal in luminous power. The two members of double stars are mostly of one color, but a difference of color is observed in about one-fifth of the whole number. In many of these cases, the one color is the complement of the other, and it is possible that the color of the smaller star may be subjective, arising from the action of the other upon the eye.

It was in 1803, after 20 years' observation, that Sir W. Herschel advanced the view, which has been more and more confirmed since, that double stars are connected systems of two or more stellar bodies, revolving in regular orbits around one another, or rather round their common center of gravity. Their motions are found to follow the same laws as prevail in the solar system, and the orbits are elliptical. These distant bodies are therefore subject to the Newtonian law of gravitation. The period of revolution has, in several cases, been roughly approximated: among the shortest is that of ζ Herculis, estimated at 30 years; others are set down at hundreds. In cases where the parallax is known, the size of the orbits can be determined; and thus the astronomer is able to assert in regard to the double star 61 Cygni that the orbit described by these two stars about each other undoubtedly greatly exceeds in dimensions that described by Neptune about the sun. Even the masses of these stars have been calculated as being together 0·353, that of our sun being 1. It is a consequence of these revolutions that many stars are now seen double that formerly seemed single, and *vice versâ*. If the plane of revolution have its edge presented to the earth, the stars will seem to move in a straight line, and at times to cover one another. The star ζ Herculis, seen by Herschel double in 1781, appeared single in 1802, and was first seen double again by Struve in 1826. The

Fig. 1.

figure represents the relative positions of the two stars composing γ in Virgo, at different times since the earliest observations. The period of revolution is presumed to be 182 years.

The *proper motion* of stars, discovered by Halley, is of another kind. It consists in a displacement in various directions of the

individual stars, so that the configuration of constellations is slowly changing. 'The Southern Cross,' says Humboldt, 'will not always shine in the heavens exactly in its present form; for the four stars of which it consists move with unequal velocity in different paths. How many thousand years will elapse before its total dissolution cannot be calculated.' The proper motions yet observed vary from $\frac{1}{10}$th of a second to 7″·7. According to Bessel, the proper motion of the binary star 61 Cygni amounts to 5″·123, so that in 360 years it would pass over a space equal to the moon's diameter. It must thus take thousands of years to alter sensibly the aspect of the heavens; although, taking into account the enormous distances, the actual velocities must be great. Of 3000 stars observed by Bessel, 425 had a perceptible motion. Argelander has recently published a list of 560 stars having a proper motion.

It was first observed by Sir W. Herschel that there is a perceptible tendency in the stars generally to diverge or open up in one quarter of the heavens, and to draw together in the opposite quarter; and this he attributed to a proper motion of our sun with his planets in the direction of the former point. The apparent motion thus caused is complicated with the real independent motions of individual stars. The point towards which this motion is directed, which is called the 'solar apex,' was fixed by Herschel in the constellation Hercules; and the result of subsequent and independent researches gives a nearly coincident point. The velocity has been calculated at upwards of 150 millions of miles a year, or 17,600 miles an hour—i. e., rather more than one-fourth of the earth's velocity in its orbit.

The spectroscope has been applied to investigate the physical constitution of the stars, with the result of identifying many of the elements composing our sun and earth. The spectra of the stars differ greatly among one another; some consisting mainly of simple lines, others having complex bands. The simple spectra are believed to indicate great intensity of heat, keeping the molecules of matter in a state of extreme dissociation; while the complex spectra show the molecules to be more associated in groups or compounds, owing to the repulsive force being less. The bluish stars are the hottest; a red tinge indicates a comparative coolness. Our sun would seem to be a decaying star.

Several stars exhibit well-marked periodic alterations of a striking nature, and are hence called *variable stars*. A considerable number have been observed, of which the most remarkable are Mira (the 'wonderful') in Cetus, and Algol in Perseus. The first attains its greatest lustre every 334 days, and appears for 14 days as a star of the second, and even at times of the first magnitude; it then decreases for two or three months, till it becomes of the

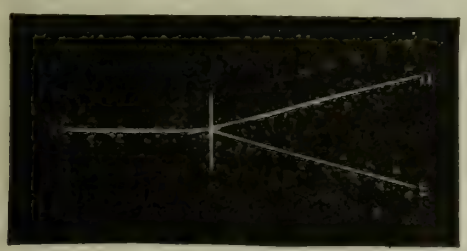


Fig. 2.

sixth and even tenth magnitude, so as to be for half a year invisible to the naked eye and usually to telescopes. After this it begins again to increase, but more rapidly than it decreased. It is visible to the naked eye for three or four months of its period. Of all the variable stars yet observed in Perseus, Algol has the shortest period, being 68 hours 49 minutes. It appears for about 60 hours a star of the second magnitude, then decreases for four hours, and appears for a quarter of an hour of the fourth magnitude, after which it increases again for four hours. Various explanations have been offered of these mysterious appearances; the stars are supposed to turn on their axes, and to have their surfaces unequally luminous in different places; or a large dark body is assumed to be revolving about the luminous one, so as to intercept more or less of its light in different positions; or the stars are lens-shaped, &c. There is nothing, however, inadmissible in the supposition that the intensity of the light itself may vary; and if in other suns, why not in our own?

Fig. 3.

Allied to the variable stars are the *new* or temporary stars that appear suddenly in great splendor, and then disappear without leaving a trace. A number of instances are on record. It is not impossible that these also may be periodic.

Star Systems.—From the appearances connected with the Milky Way or Galaxy (q. v.), Sir W. Herschel came to the conclusion that the stars forming our firmament do not extend indefinitely into space, but are limited in all directions, the mass having a definite shape. He conceived the shape to be something like that of a huge millstone, having one side cleft, and the two laminæ set apart at a small angle. Let the diagram (fig. 2) represent a vertical section of such a broad flat stratum, and suppose the solar system situated as at S, to a spectator looking on either side, in the direction of the thickness, as SB, the stars would appear comparatively sparse, but all round in the direction of the breadth (as SA) there would appear a dense ring, which would separate into two branches (SE, SD) in the direction of the cleft side. This supposition accounts for the appearance of the Milky Way, and all subsequent observations have tended to confirm the conjecture. Situated as we are within the system, we cannot hope ever to attain more than a rude notion regarding it; to get a definite outline, we must be placed without it.

But this star system, which we may call our own, as our sun belongs to it, is but an item in the stellar universe. The appearances known as nebulæ, in many cases at least, are believed to be similar agglomerations of suns, separated from our system and from one another by unfathomable starless intervals (see NEBULÆ). Their forms are very various, but in general pretty well defined, and not without symmetry. The aspect of some of them is even startling. A few specimens are given in the woodcut (fig. 3).

STAR-THISTLE. See CENTAUREA.

START POINT (A.-S. *steort*, a tail or promontory), a rocky headland in the south of Devonshire, with a lighthouse 204 feet above the sea, in lat. 50° 13′ 4″ N., and long. 3° 38′ W.

STARVA'TION, or INANI'TION, are terms applied to the phenomena resulting from an entire deficiency, or an insufficient supply of food. From M. Chossat's well-known experimental investigations of this subject (*Recherches Expérimentales sur l'Inanition*, Paris, 1843), it appears that the average loss of weight in mammals and birds, between the commencement of fasting and the death of the animal, was 40 per cent., the loss varying above and below 40 per cent. in the different organs and tissues, as shown in the following table:

PARTS WHICH LOSE MORE THAN FORTY PER CENT.		PARTS WHICH LOSE LESS THAN FORTY PER CENT.	
Fat	93·3	Muscular coat of Stomach	39·7
Blood	75·0	Pharynx and Œsophagus	34·2
Spleen	71·4	Skin	33·3
Pancreas	64·1	Kidneys	31·9
Liver	52·0	Lungs	22·2
Head	44·8	Bones	16·7
Intestines	42·4	Eyes	10·0
Muscles of Locomotion	42·3	Nervous System	1·9

Hence it appears that there is an almost complete removal of the fat, and a great reduction of the blood, while the nervous system is scarcely affected; and hence it would seem as if the supervention of death was coincident with the consumption of all the combustible materials of the body, and that previously the remaining nutritive force was concentrated on the nervous system.

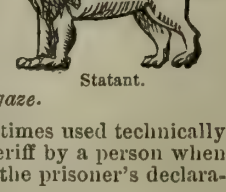
The following are amongst the most prominent phenomena which Chossat observed either during the experiments or after the death of the animals: 1. Dropsical effusions. 2. Softening and destruction of the mucous membrane. Blackening of the viscera, especially of the liver. 4. Bluish, livid, yellow, and reddish stains during life in the transparent parts of the skin. 5. Hectic fever, and a continuous decrease in the power of the body to resist cold. 6. At first a scanty excretion of dry, bilious, grass-green fæces, and afterwards diarrhœa of liquid saline matter. 7. Convulsions similar to those in death by hæmorrhage. 8. Death

by starvation seems to be in reality death by cold; since the temperature of the body is not much diminished until the fat is nearly consumed, when it rapidly falls, unless it be kept up by heat applied externally. 9. Young animals succumbed far sooner than adults. 10. The results of insufficient food were in the end the same as those of total deprivation; the total amount of loss being almost the same, but the rate being less, so that a longer time was required to produce it.

Chossat did not find that much influence was exerted on the duration of life by permitting or withdrawing the supply of water; but there is no doubt that in man, and probably in mammals generally, death supervenes much earlier when liquids as well as solid food are withheld. For a full account of the symptoms of starvation as they occur in the human subject, we must refer the reader to the writings on hygiene and forensic medicine of Orfila, Rostan, Caspar, Taylor, &c.; and especially to Dr. Donovan's account of the Irish famine of 1847, in the *Dublin Medical Press*, Feb. 1848, p. 67. The following are the most striking symptoms: In the first place, pain is felt in the stomach, which is relieved on pressure. The countenance becomes pale and cadaverous; the eyes are wild and glistening; the breath hot, the mouth parched, and the saliva thick and scanty. An intolerable thirst surpervenes, which, if there be no access to water, becomes the most distressing symptom. The body becomes gradually emaciated, and begins to exhale a peculiar fœtor, while the skin becomes covered with a brownish dirty-looking, and offensive secretion almost as indelible as varnish, which Donovan at first mistook for encrusted filth. The bodily strength rapidly declines; the sufferer totters in walking, like a drunken man; his voice becomes weak and whining, and he is ready to burst into tears on the slightest occasion. In the cases recorded by Donovan, imbecility, and sometimes almost complete idiocy, ensued, but in no instance was there delirium or mania, which has been described as a symptom of starvation in cases of shipwreck. On examination after death, the condition of the body is such as might be expected from Chossat's experiments, viz., extreme general emaciation; loss of size and weight of the principal viscera; almost complete bloodlessness, except in the brain; and the gall-bladder distended with bile, which tinges the neighboring parts. Moreover, decomposition rapidly ensues.

It is impossible to fix the exact time during which life can be supported under entire abstinence from food or drink. Dr. Sloan has given an account of a healthy man, aged 65, who was found alive after having been shut up in a coal mine for 23 days, during the first ten of which he was able to procure a small quantity of foul water. He was in a state of extreme exhaustion, and notwithstanding that he was carefully nursed, he died three days after his rescue. Dr. Willan records the case of a young gentleman who, under the influence of religious delusion, starved himself to death. He survived for sixty days, during which time he took nothing but a little orange juice. In this case life was probably abnormally prolonged in consequence of the peculiar emotional excitement of the patient. Judging from the cases of abstinence owing to disease of the throat and impossibility of swallowing, Dr. Taylor infers 'that in a healthy person under perfect abstinence, death would not commonly take place in a shorter period than a week or ten days.'

It is worthy of notice that a deficient supply of food seems to check the elmination and removal of the effete materials of the of the body. This fact accounts not only for the tendency to putrescence, which is exhibited during the process of starvation, and for the rapidity with which putrefaction ensues after death, but for the pestilential diseases which almost always follow a severe famine; the excess of disintegrated matter in the blood rendering the system especially prone to the reception and multiplication of the diseases characterized as zymotic, such as fever, cholera, &c.



Statant.

STA'TANT, in Heraldry, a term applied to an animal standing still, with all the feet touching the ground. If the face be turned to the spectator, it is said to be *statant gardant*, or in the case of a stag, *at gaze*.

STA'TEMENT, in Scotch Law, is sometimes used technically to denote the account given before the sheriff by a person when arrested on a criminal charge. It is called the prisoner's declaration in England.

STA'TEN ISLAND, a beautiful and picturesque island, which forms the W. shore of the bay and narrows, and the S. shore of the harbor of New York. It contains 58¼ sq. m., forming the county of Richmond, divided into 5 townships. Its shores are dotted with villages, and its heights crowned with villas. A narrow sound, the Kill van Kull, separates it from New Jersey. Four strong forts guard, with those on the opposite shores of Long Island, the entrance to the harbor, and the Hudson and East Rivers. There are asylums for sick or disabled seamen and families of seamen. Pop. (1880) 38,991.

STA'TEN ISLAND, an island off the south-east point of Tierra del Fuego, from which it is separated by the Strait of Le Maire. It is about 45 miles in length from east to west, and about 10 miles at its greatest breadth, its shores much indented. Its eastern extremity is Cape St. John, in lat. 54° 42′ S., and long. 63° 43′ W. The surface is mountainous, descending to the sea in steep slopes and precipices; its general character similar to that of Tierra del Fuego.

STATES, or ESTATES, in Politics, the name given to the classes of the population who either directly or by their representatives take part in the government of a country. In all European countries where the northern conquerors established themselves, the rudiments of representative government appeared in the form of assemblies brought together to deliberate with the sovereign on the common weal. These assemblies at first consisted of the two estates of the clergy and the nobility or baronage, who together constituted the whole free population of the realm; the nobility including not merely the greater barons, but the whole freeholders. As the burgesses gradually emancipated themselves, and rose into importance, they formed a third estate.

In France, we find the *tiers état*, or citizens, recognized in the States-general (q. v) in 1302. In Scotland, the earliest occasion on which the burghs are mentioned as attending and concurring in a grant of taxation, is in the Parliament held at Cambuskenneth in 1326, in which Robert Bruce set forth to the assembled estates the diminished condition of the royal income in consequence of the protracted struggle through which the country had come. The burgesses, represented by the commissioners for the burghs, continued in Scotland to be a separate estate, and were not, as in England, amalgamated with the knights and lesser barons, who, in the Scots parliament, were always classed with the baronage. The lesser barons were, however, first allowed, and latterly enjoined, to appear by representatives; and the three estates of clergy, barons, and burgesses all sat and deliberated in one house. In England, on the other hand, the knights and lesser barons were at an early period separated from the greater barons, and conjoined with the burgesses into the third estate, which occupied a separate chamber from the Lords Spiritual and Temporal. This peculiarity in the original constitution of the *tiers état* of England necessarily gave it a weight which it did not possess elsewhere, and exercised an important influence on the constitutional history of the country. As the peasants became emancipated, we also find them in some countries taking a share in the legislative power, either as a part of the *tiers état*, or, as in Sweden, forming a fourth estate. The four estates of nobles, clergy, citizens, and peasants were recognized in Sweden till 1866; and in the Swedish legislature, as constituted, each had its separate chamber.

Throughout Europe, except in Russia (though in some small German States, such as Mecklenburg, the diet, representing only the landed gentry and the towns, has very little authority), the co-operation of the estates with the sovereign in the legislative power is more or less recognized. Some assemblies have but one chamber, but more of them have two. The lower chamber is always wholly, or partly, elective, but sometimes consists of separate delegates from the different orders of the community, and has representatives of landed proprietors, of towns, of peasants, and of traders and manufacturers. The upper house or senate is in some constitutions hereditary; in some, it consists of members named by the sovereign or by the nobility, or some other class of the community, and often it combines these elements. In a few instances, as in Brazil, it is elected by the same constituency as the lower house, and differs only in the higher property qualification required of its members.

STATES-GENERAL (Fr. *états généraux*), the name which was given to the convocation of the representative body of the three orders of the French kingdom; so named in contradistinction from the *états provinciaux*, or assemblies of the provinces. As far back as the time of Charlemagne, there were assemblies of clergy and nobles held twice a year to deliberate on matters of public importance; and in these assemblies the extensive body of laws bearing the name of the Capitularies of Charlemagne was enacted. The succeeding centuries, however, were adverse to free institutions; and these national convocations, becoming gradually less important, seem to have ceased to be held about 70 years after Charlemagne's death. From that time forward there is no trace of any national assembly in France till 1302, when the *états généraux*, including the three orders of clergy, nobles, and citizens, were convened by Philippe le Bel, with the view of giving greater weight to the course adopted by the king in his quarrel with Pope Boniface VIII.

In 1314, we find the States-general granting a subsidy: during the reigns of Philippe IV. and his successor, the imposition of taxes by arbitrary authority was the subject of general discontent;

and in 1355, the states were strong enough to compel the government to revoke the taxes so imposed. The States-general, however, though their consent seems in strictness to have been considered requisite for any measure imposing a general taxation, had, unlike the assemblies under the Carlovingian kings, no right of redressing abuses except by petition, and no legislative power. Under Charles VI. and Charles VII. the States-general were rarely convened, and it was often found more convenient to ask supplies from the provincial states. But as the royal authority increased, the formality of any convention of states general or provincial gradually ceased to be regarded as indispensable, and a final and unsuccessful struggle for immunity from taxation took place at the States-general of Tours in 1484. Louis XIII. convoked the States-general, after a long interval, in 1614, but dismissed them for looking too closely into the finances; and from that time down to the Revolution, the crown, with the tacit acquiescence of the people, exercised the exclusive powers of taxation and government. In 1789, the memorable convention of the States-general took place, which ushered in the Revolution. As soon as they had assembled, a dispute arose between the two privileged orders and the third estate as to whether they should sit and vote in one chamber or separately. The *tiers état*, of its own authority, with such deputies of the clergy as chose to join them—none of the nobles accepting their invitation—assumed the title of the *Assemblée Nationale*, a name by which the States-general had previously been sometimes designated. See ASSEMBLY, NATIONAL.

The name States-general is also applied to the now existing legislative body of the kingdom of the Netherlands (q. v.). It is so called in contradistinction from the provincial states, which are legislative and administrative assemblies for the several provinces.

STA'TICÉ, a genus of plants of the natural order *Plumbagineæ*, having a funnel-shaped, membranaceous, and plaited corolla; the flowers in spikes on one side of a panicled, leafless, flowering stem (*scape*). Several species are natives of Britain, growing near the sea, most of them on muddy shores and in salt marshes. The root of *S. Caroliniana*, called Marsh Rosemary, is used in North America for all the purposes of kino and catechu, and is a very powerful astringent.

Staticé Simonum.

STA'TICS (Gr. root *sta*, to stand), the science of the equilibrium or balancing of forces on a body or system of bodies, has gradually advanced from the days of Archimedes to the vast developments it has now acquired. Singularly enough, though most of its simpler theorems are very generally known, are almost popular, in fact, there is no science in which elementary teaching is so defective. The ordinary proofs of its fundamental principles, such as the *Parallelogram of Forces*, the *Principle of the Lever*, &c., are usually founded on the supposition that a body in equilibrium is *absolutely at rest*. Now, any one who knows that the earth rotates about its axis, that it revolves about the sun, that the sun is in motion relatively to the so-called fixed stars; that *they* are, in all probability, in motion about something else which is itself in motion, &c., will at once see that there is no such thing as absolute rest, and that *relative rest* or motion, unchanged with reference to surrounding bodies, is all that we mean by equilibrium. He will then, at once, see that the foundations of statics are to be sought in the LAWS OF MOTION (q. v.). And, in fact, Newton's Second Law of Motion gives us the necessary and sufficient conditions of equilibrium of a single particle under the action of any forces; while his Third Law, with the annexed Scholium, gives these conditions for any body or system of bodies whatever.

The simplest statement of the conditions of equilibrium of a rigid body which can be given, is that furnished by this Scholium of Newton's, which is now known by the name of the Principle of Energy (see FORCE) or Work (q. v.). It is as follows: A rigid body is in equilibrium if, and is not in equilibrium unless, in *any* small displacement whatever, no work is done on the whole by the forces to which it is subject. In the case of what are called the *Mechanical Powers* (q. v.). this is equivalent to the statement, that work expended on a machine is wholly given back by the machine—or that the work done by the *power* is equal to the work spent in overcoming the *resistance*.

It is shown in the geometrical science of Kinematics that any motion whatever of a rigid body can be reduced to *three* displacements in any three rectangular directions, together with *three* rotations about any three rectangular axes—so that the equilibrium of a rigid body is secured if no work be done on the whole in any of these *six* displacements. There are thus six conditions of equilibrium for a rigid body under the action of any forces—and these are reduced to *three* (two displacements and one rotation), if the forces are confined to one plane; and to *one* (a displacement), if the forces act all in one line.

Equilibrium may be *stable*, *unstable*, or *neutral*. It is said to be stable, if the body, when slightly displaced in any way from its position of equilibrium, and left free, tends to *return* to that position. It is unstable, if there is any displacement possible, which will leave the body in a position in which it tends to *fall further away* from its position of equilibrium. It is neutral, if the body, when displaced, is still in equilibrium. It is easily shown, but we cannot spare space for the proof, that a position of stable equilibrium is, in general, that in which the Potential Energy (see FORCE) of the body is a minimum—of unstable equilibrium, where it is a maximum (for some one direction of displacement at least) —of neutral equilibrium, where the potential energy remains unchanged by any small displacement. Thus, a perfect sphere, of uniform material, is in neutral equilibrium on a horizontal plane—while an oblate spheroid, with its axis of rotation vertical, is in stable equilibrium; and a prolate spheroid, with its axis vertical, is in unstable equilibrium on the plane. Similar statements hold for other than rigid bodies. Thus, a chain, or a mass of fluid, is in stable equilibrium when its potential energy is least, i. e., when its center of gravity is as low as possible. This simple statement is sufficient for the mathematical solution of either question.

STA'TIONERY, a very general term applied to the materials connected with writing, such as paper, books for accounts, drawing, &c., envelopes, sealing materials; and even writing-desks, blotting-books, albums, porte-feuilles, pocket-books, red tape, and many other necessaries of the writing-desk, are included.

STATIONERY OFFICE, an office in London established by the Lords of the Treasury in 1786, for the purpose of purchasing, wholesale, writing materials for the supply of the government offices at home and abroad. It also contracts for the printing of all Reports and other matters laid before the House of Commons. The duties are performed by a comptroller, a storekeeper, and about thirty clerks or other subordinate officers. There is a branch establishment in Dublin. The appointments are made by the Lords of the Treasury.

STATIONS (Lat. *statio*), a name applied in a Roman Catholic Church to certain places reputed of special sanctity, which are appointed to be visited as places of prayer. The name is particularly applied in this sense to certain churches in the city of Rome, which, from an early period, have been appointed as churches which the faithful are particularly invited to visit on stated days. The names of these churches are found on the several days in the Roman missal prefixed to the liturgy peculiar to the day. The word, however, is employed in a still more remarkable manner in reference to a very popular and widely-received devotional practice of the Roman Catholic Church, known as that of 'The Stations of the Cross.' This devotion prevails in all Catholic countries; and the traveler often recognizes it even at a distance by the emblems which are employed in directing its observance—the lofty 'Calvary' crowning some distant eminence, with a series of fresco-pictures or bas-reliefs arranged at intervals along the line of approach. These representations, the subjects of which are supplied by scenes from the several stages of the Passion of our Lord, are called Stations of the Cross, and the whole series is popularly known as the *Via Calvaria*, or Way of Calvary. The origin of this devotional exercise, like that of local pilgrimages, is traceable to the difficulty of access to the Holy Places of Palestine, consequent on the Turkish occupation of Jerusalem and the Holy Land; these representations being designed to serve as some analogous incentive to the piety and faith of the Christian worshiper of our Lord in his Passion. The number of the so-called 'stations' is commonly 14, although in some places 15, and in others, as Vienna, only 11; but whatever may be their number, the subject of all is a sort of pictorial narrative of the Passion. The devotional exercise itself is performed by kneeling at the several stations in succession, and reciting certain prayers at each. Forms of prayer are prescribed to those who can read. The poor and ignorant recite the Lord's Prayer and Hail, Mary! all being directed to fix their thoughts in grateful memory upon 'the sufferings which each representation describes our Lord as having undergone, in atonement for the sins of mankind.' Many 'indulgences' are granted to those who having duly repented of their sins, shall piously perform this exercise. Many of these stations are celebrated as works of art, especially one near Bologna. Some of those in the Alps and along the precipitous banks of the Rhine, Danube, and other German rivers, are exceedingly striking and picturesque.

STATI'STICS, that branch of Political Science which has for its object the collecting and arranging of facts bearing on the condition, social, moral, and material of a people. The word statistics was first employed in the middle of last century by Professor Achenwall of Göttingen, who may be considered the founder of the science. The principle lying at its foundation is, that the laws which govern nature, and more especially those which govern the moral and physical condition of mankind, are constant, and are to be discovered by the investigation and comparison of phenomena extending over a very large number of instances. Accidental diversities tend to neutralize each other, their influence diminishing as the area of investigation increases; and if that area be sufficiently extended, they so nearly disappear, that we are entitled to disregard them altogether. While the length of a single life cannot be counted on, an average of 1000 or 10,000 lives gives us a constant quantity, sufficiently near the truth to answer the purposes of insurance companies. Even the acts which are the most purely voluntary as regards individual men, have been found to be subject to laws which, in respect of the masses which make up society, are invariable in like circumstances, and discoverable.

The science of statistics has a twofold relation to political and social economy. The facts collected by the statist are the bases on which political economy rests; their application to social and economical problems is an appeal from imagination to fact. But the statist must be guided by the political economist in what direction to extend his investigations: without political economy, we should have had no statistics.

It would be difficult to give any exhaustive enumeration of the multifarious topics which may be the subject of statistical inquiries. The results of statistics have been classified as—1. Problems regarding the nature of wealth and its production and growth in a community; 2. Problems relating to inland and foreign trade; 3. Problems relating to taxation and finance; 4. Problems regarding currency, banks, and prices; 5. Problems relating to the wages and hire of labor, and the division of employments; and 6. Problems relating to the functions of the state as regards interference with the economic relations of its subjects.

The Statistical section added to the British Association for the Advancement of Science in 1833, and the London Statistical Society founded in 1834, have made some valuable contributions to this science, and helped to diffuse a knowledge of its principles and its importance. But while in some branches there is undoubtedly room for the labors of individuals or associations, statistics are, generally speaking, more appropriately the province of the state. The most important of the subjects with which this science is cognizant, cannot be investigated without unrestricted access to government offices, and authority to demand information; and the ordinary administration of government is continually affording opportunities for the collection of the most valuable statistical facts. For some time past, statistics have largely occupied the attention of the more enlightened governments of Europe. The statistical reports issued by the various departments of the French government deserve especial praise for the comprehensiveness of their basis, and the clearness of their arrangement. The government of Belgium has, since 1841, engaged with much diligence in statistics, and Austria and Prussia have also their Statistical departments. In the United Kingdom, a department of the Board of Trade has, since 1832, been charged with collecting and publishing detailed and classified information obtained from various departments of government regarding the revenues, population, commerce, wealth, and moral and economical condition of the country and colonies, as well as a selection from the statistics of foreign countries. Every session of parliament, there are also numerous statistical returns called for, which no doubt sometimes contain valuable material, but being drawn up to suit the particular purpose of those who move for them, they have too often a desultory, fragmentary character, and from the absence of any general plan, are of little use but for the moment. It has been suggested that, by establishing a separate Statistical department of government, we might, at a hardly greater cost, obtain a yearly *résumé* of administrative statistics complete enough to supersede to a large extent the present system of moving for returns whenever they are wanted.

The frequent connection of statistics with political theories renders it important to guard against premature statistical conclusions, of which two very fertile sources are calculations from an insufficient number of data, and neglect to make allowance for disturbing causes.

STA'TUARY AND STATUE. See SCULPTURE.

STA'TUTE OF FRAUDS, in English Law, is a statute which required certain contracts and agreements to be in writing, in order to be binding in such cases. The object of the statute, 29 Char. II. c. 3, was to prevent the perjury which so frequntly takes place where the proof of the contract is left to the memory of the parties. All leases for more than three years, and their assignments, must be in writing; and no freehold estate in lands can be created except by writing. So promises and agreements to bind an executor or administrator personally must be in writing; as well as to bind one party for the debt of another. So as to contracts made for the sale of land, or of interests in land; and for the sale of goods above £10 in price, unless part of the goods have been accepted and received, or partly paid for.

STATUTE OF LIMITATIONS. See LIMITATION.

STATUTES OF DISTRIBUTIONS. See DISTRIBUTIONS.

STATUTES, or ACTS OF PARLIAMENT, are those laws made from time to time by the legislature, which qualify and alter the common law or previous statutes. All laws may be divided into common law and statutory law, the former being unwritten, the latter being written. The theory as to the common law is, that it consists merely of ancient usages, accepted by all, of which the written exposition has perished, but which tradition has kept alive; and much of the common law necessarily consists of what has sometimes been called judge-made law—a department of law which has often been ignorantly denounced as illegal or unconstitutional, but which is a necessary part of every code, under whatever name it is disguised.

The legislature of England consists of the Queen, Lords, and Commons in parliament assembled, and the statutes which they pass have been likened by Sir Matthew Hale to written contracts or indentures, the general public being bound, by their respective agents, as if by solemn deed. There is no legal mode of altering the previously existing law, except by a statute passed with the consent of parliament; but there are other ways of modifying the law, so far as mere details of administration are concerned—as, for example, by orders in council, by ordinances, by charters, and by by-laws issued under some inherent or statutory power belonging to corporations. The mode in which a statute is made belongs properly to the head of Procedure in Parliament. Statutes or acts of parliament are all founded on the theory that the legislature has an inherent right to alter all previous laws or statutes; and though sometimes great and leading statutes have been declared to be unalterable by any future parliament, this restriction is obviously utterly futile, and inconsistent with the idea of a legislature. Statutes are usually divided, according to the number of persons affected by them, into public and private—the former applying to the whole public, the latter only to the persons named or described. There is also a subdivision of both into local and personal statutes. Statutes are also divided into declaratory, penal, or remedial, according to the nature of their object. There are certain important rules as to the interpretation of statutes, the chief business of the various courts of law and equity being to construe or interpret the statutes. A statute begins to operate from the time when it receives the royal assent, unless it state some other time for its commencement; but formerly each statute was presumed to take effect from the beginning of the session of parliament in which it passed, until the rule was changed, in 1793, by the act 33 Geo. III. c. 13.

The leading rule in construing statutes is, that the words are to be taken in their ordinary grammatical sense, unless the context shows that they are used in some other sense. All other rules resolve more or less into this. There is also a well-known rule that penal statutes are to be construed less strictly than other statutes of a remedial kind. Another rule is, that a subsequent statute repeals one that is prior, either expressly or by necessary implication, if the prior one is inconsistent in substance. Though it might seem an easy task to construe or interpret what is meant by a statute, it is in practice so far from being easy, that it requires a special training and long experience to arrive at an accurate mode of construction, the chief business of lawyers being to acquire this art; and one excels another solely or chiefly by virtue of the tact, skill, and accuracy of thinking which are required to do such work in perfection. All the main disputes in litigation turn chiefly on the different interpretations put by parties on statutes or contracts, both of which are construed according to precisely the same rules. Another rule applicable to statutes is, that each remains in force until it is repealed, either expressly or impliedly. So much confusion, however, has arisen out of the multiplicity of statutes, and it is so difficult for lawyers to discover what statutes have been so impliedly repealed, that, of late years, a process of revision and examination has been instituted by the government with a view to repeal expressly all that is obsolete and that is already only impliedly repealed, so as to reduce the bulk of the statutes, which have now grown to an inconvenient size. This task is preliminary to a codification of those statutes which remain after such revision and expurgation.

STAUBBACH, FALL OF, a celebrated waterfall in the southern part of the canton of Bern, Switzerland, a mile from the village of Lauterbrunnen, and 8 miles south of Interlaken. It is one of the loftiest in Europe, having a descent between 800 and 900 feet, but it often disappoints visitors, who expect a swift loud-roaring cataract, and find instead a slender stream of water, concealing

the face of the precipice like a 'beautiful lace veil, and imitating in its center the folds of the drapery.' Long before it reaches the bottom, it is blown into a dust of silver spray, whence its name *Staubbach* (Dust-stream). Both Byron and Wordsworth have praised it in verse.

STAUNTON, a rapidly increasing town of Virginia, U. S., on a branch of the Shenandoah River, 100 miles west-north-west of Richmond. It was incorporated in 1749, and is the site of the Western State Lunatic Asylum, and the Deaf and Dumb and Blind Asylums. It contains 9 churches, 3 newspapers, several academies and seminaries, mills, foundries, and manufactories. Pop. (1880) 6664.

STAVANGER, a seaport town of the west coast of Norway, in the stift of Christiansand, 35 miles north-west from the Naze, and 100 miles south from Bergen, on the west side of a wide and sheltered bay of the Bukne-fiord. It is a very ancient town, with a very fine old Gothic cathedral, built in 1013. S. has cloth-manufactories and distilleries. Ship-building is carried on. There is a considerable export trade in timber, oak-bark, lobsters, herring, and stock-fish. Pop. (1876) 20,288.

STAVESACRE. See LARKSPUR.

STAVESACRE (*Delphinium staphisagria*), a species of Larkspur (q. v.), a native of the south of Europe. The seeds have been used in medicine from ancient times. They are too violently emetic and cathartic to be safely employed; but in powder they are pplied to cutaneous eruptions, and are used for killing lice. Their properties depend upon an alkaloid *Delphinia* ($C_{27}H_{19}NO_7$), which is now used in medicine instead of the seeds, chiefly in rheumatism and neuralgia.

STAVROPOL, a government in Russian Caucasia, bounded by the Caspian Sea, on the E., and by the Caucasus on the S. Area, 27,000 sq. m.; pop. (1880) 475,000. The chief rivers are the Kuban and Terek, and the Kuma. In the southwest, where the soil is fertile, and produces millet and wheat, agriculture is the chief employment; in the north-east, the inhabitants lead a nomad life. Vineyards line the banks of the Terek and Kuma, and mulberry trees are cultivated for the rearing of silk-worms.

STAVROPOL, capital of the government, stands on the chief highway from Europe to the Caucasus, 200 miles south-east of Rostov. Pop. (1880) 34,350.

STAY, STAYSAIL. See RIGGING, SAIL.

STEALING. See LARCENY.

STEAM. Steam is water in the gaseous form (see HEAT). When dry, it is invisible and transparent, like air, and is not to be confounded with *vapor*, which is steam returned to the state of water, and thus become visible—water-dust, as it were. As steam has become the most important of all motive powers, the properties on which its action depends deserve careful consideration. The development of steam is, naturally enough, connected popularly with a high temperature, but the two things do not necessarily go together. Water (or snow, or ice) gives off vapor or steam at *every* temperature—a low temperature not preventing the formation of steam, but only decreasing its density. The only limit to this evaporation is when the air surrounding the water (or snow, &c.) is already saturated with vapor of the maximum density which the water can give off at the existing temperature. Thus water at 32° F. will give off vapor of a pressure equal to 0·085 pound per square inch; but if the air above it is already saturated with vapor of that density, the tendency of the particles of water to fly apart is exactly balanced by the pressure of the vapor on its surface, and no more evaporation takes place.

It is a remarkable fact, that while no atmospheric pressure can prevent the water or ice passing into vapor, the previous presence in the air of vapor of the required density (even when so small as in the instance just given) entirely stops it.

We may make this more clear by an illustration. Suppose *a* to be a cylinder, and *pp* a piston moving steam-tight within it; and suppose also that the end of the cylinder above *p* is open to the atmosphere, and that below *p* there is in the cylinder a perfect vacuum. There is then a downward pressure upon the piston equal to the whole force of the atmosphere, or about 14·7 pounds per square inch. If, now, a little water could be introduced into the bottom of the cylinder, without admitting any air, a quantity of vapor would rise from it, and press with more or less force on the lower side of the piston, so as to sustain a portion of the weight of the atmosphere. How much vapor would rise, and how much elastic force or pressure it would exert, would depend upon the temperature of the water and cylinder.

At 32° F., as we have already said, the vapor in the space *a* would exert a pressure equal only to 0·085 pound per square inch. If the temperature were raised to 80°, more vapor would rise until its pressure became about 0·5 pound per square inch; at 102°, the pressure would be 1 pound; at 162°, 5 pounds; at 193°, 10 pounds; and so on, until at 212° F. the pressure would be 14·7 pounds, or exactly equal to that of the atmosphere. When this point has been reached, it is evident that the piston will be *in equilibrio*, the pressure beneath it being exactly equal to that above. At each intermediate point, the downward pressure on *pp* is equal to the pressure of the atmosphere, *minus* the pressure of the steam below the piston. So far as the piston is concerned, the conditions are therefore the same as if the vacuum had been impaired by the introduction of a certain quantity of *air* below *pp*; but there is this difference between the two cases: if the space *a* had been occupied by rarefied air, then, by forcing the piston down, and compressing it into less space, its density would increase until its pressure became equal to, or greater than that of the external air. With steam, however, if the piston were depressed, *and if the temperature of the steam were preserved the same*, instead of its pressure being increased, a portion of it would be liquefied, and the remainder would have the same pressure as before.

It is at 212° that water in an open vessel begins to boil; that is, the vapor rises rapidly and in volumes, being able to displace the atmosphere (see BOILING). In this state, it is usually called *steam;* but there is no essential difference between steam at 212° and steam at 60°. The steam rising from boiling water in an open vessel is of the same temperature as the water—viz., 212°; but notwithstanding this, it contains a great deal more *heat*. This heat is employed in (to use popular language) forcing asunder the molecules of the steam, and thus causing it to occupy so much greater a bulk as steam than as water. It does not make itself known by the thermometer (for which reason it is called *latent* heat), but its existence and amount are known by other means, for which see the article HEAT.

It is important to note, before going further, that, in speaking of the pressure of steam, we have given it in pounds per square inch above a perfect vacuum, or in what are called *absolute* pressures. These must be carefully distinguished from pressures (as often given) in pounds *above atmospheric pressure*. According to the method we adopt, which is the more scientific one, steam of 14·7 pounds, or one atmosphere, exactly balances the pressure of the air, and can therefore do no work against it; while, if the other nomenclature had been adopted, steam of 14·7 pounds *above* atmospheric pressure would have been really steam of *two* atmospheres pressure. In reading on this subject, the student should always make sure whether the pressures spoken of are measured above an absolute zero, or only above the atmospheric pressure, as much confusion is sure to result from any mistake on this point.

When a cubic inch of water is converted into steam at the ordinary pressure of the atmosphere, its volume is increased to 1645 cubic inches—i. e., a cubic inch of water becomes nearly a cubic foot of steam of one atmosphere. If the steam is produced at any greater pressure, its volume will be very nearly inversely as that pressure; at two atmospheres, it would occupy about 855 cubic inches; at four atmospheres, about 457 cubic inches.

When water is boiled in an open vessel, neither the temperature of the water, nor that of the steam rising from it, ever rises higher than 212°, however hot the fire; the heat as it enters is carried off in a latent state in the steam. But under pressure, the temperature of both can be raised to any degree. If, when the water and steam in *a*, fig. 1, came to 212°, the application of heat were still continued, more steam would continue to rise, and the pressure on the under side of the piston being now greater than that of the air above it, the piston would begin to ascend; but, suppose it held in the same position by force, the upward pressure of the steam would be found rapidly to increase, until it would soon require a weight of 14·7 pounds per square inch to keep it down, showing that the pressure of the steam was now equal to twice that of the atmosphere, or to 29·4 pounds per square inch. If at this point the temperature of the water and steam were examined, it would be found to be very nearly 250° F. When the absolute pressure of the steam reached 50 pounds, its temperature would be 281°; at 100 pounds, 328°; at 150 pounds, 360°, and so on.

From the numerous experiments made on this subject, some very important general conclusions may be drawn. Of these, one—which will be evident from the figures just given—is, that the pressure of steam increases at a far higher rate than the temperature (doubling the temperature increases the pressure *nearly* 23 *times*), which shows the extreme danger of continuing to apply heat to a vessel from which the steam is not allowed to escape. The bursting force would soon become such as no vessel could resist.

Another general conclusion of great importance is, that for every temperature there is a corresponding density of steam produced. This steam contains a fixed amount of latent heat, and exerts a certain uniform pressure on every side of any vessel in which it may be contained. The following table shows the rela-

tion between these values for steam of several different temperatures:

T.	*p.*	H.	V.	*v.*
32°	0·085	1091·8	3390·0	211.536
104°	1·06	1113·7	312·8	19.519
158°	4·51	1130·1	80 02	4,993
212°	14·7	1146 6	26·36	1,645
248°	28·83	1157·5	14·0	874
293°	60·4	1171·2	6·992	436
356°	145·8	1190·4	3·057	191
401°	250·3	1204 1	1·838	115

T, Temperature in degrees Fahrenheit. This corresponds to the *sensible heat* of the steam.
p, Pressure in pounds per square inch of the steam at that temperature.
H. Total heat of the vapor above 32° F. at that temperature (according to Regnault's hypothesis) in *thermal units*. A thermal unit (772 foot-pounds) is the quantity of heat which will raise 1 pound of water 1° F. at or near its temperature of greatest density, 39·1° F. The specific heat of water increases slowly as the temperature rises, so that 1 thermal unit will not raise 1 pound of water quite so much as 1° at high temperatures; but for the purposes of this article we need not take this into account.
V, Volume in cubic feet occupied by 1 pound of steam.
v, Number of times which volume of steam exceeds that of same weight of water.

The relations between temperature and pressure in the foregoing table apply only so long as the steam is in contact with the water from which it is generated. Once away from the water, its temperature may be raised without altering its pressure. Steam which has received additional heat in this way is called *superheated* steam. It approximates to the condition of a perfect gas, and therefore follows nearly what is known as Boyle's or Mariotte's Law (q. v.); its volume varying always inversely as its pressure. By this law, steam which occupied 1 cubic foot at 20 pounds absolute pressure, would occupy 4 cubic feet at 5 pounds, and half a cubic foot at 40 pounds absolute pressure.

Steam, however, as commonly used in the steam-engine, is not superheated, but used under the conditions given in the table. It is then called *saturated* steam, and differs sensibly from the condition of a perfect gas. If the pressure (p) be given in pounds per square inch, and the product (pv) of pressure and volume in foot-pounds, then the formula,

$$\log. (pv) = 4·675 + ·061 \log. p,*$$

gives results accurate enough at all ordinary pressures, and can be very easily applied. The volume, instead of increasing inversely as the pressure, increases less rapidly; the difference, though not very great, is large enough to be taken into account in all calculations as to the efficiency and behavior of steam in a steam-engine.

Another fact regarding the constitution of steam, requires attention, from its importance in point of economy. It would naturally be expected that it would take much more heat or fuel to convert a pound of water into steam at a higher than at a lower temperature and pressure. In reality, however, the difference is very slight. Referring back to the table, it will be seen that it requires 1146·6 units of heat to raise a pound of water from 32° to 212°, and evaporate it at that temperature; of these, 180 are expended in raising the temperature, while 1146·6 — 180, or 966·6 units, become latent in the steam. It only requires 1171·2 units however (261 sensible, and 910·2 latent), to raise the water to 293°, and evaporate it at that temperature; for the latent heat falls nearly as fast as the sensible heat rises. The additional heat required is thus only a little over 2 per cent., while the pressure—which is, *cæteris paribus*, a measure of the work the steam will do—is more than quadrupled. In this way, a large increase of power in any engine may be obtained by a small additional expenditure of fuel, and consequently steam of a high pressure is now being used for all purposes, its economy and advantages being fully recognized by engineers. It was thought for a long time that the *total* heat of steam—that is, the sum of the sensible and latent heats—was constant at all temperatures; but this is not strictly the case, although the table shows that the difference, for ordinary ranges of pressure, is but trifling. See HEAT and STEAM-ENGINE.

STEAM-CARRIAGE. Very early in the history of steam locomotion, projects were formed for running steam-carriages on common roads—not to draw a train of vehicles after them, but each carriage to have passenger-accommodation as well as steam-power. Robison suggested such a thing to Watt so far back as 1759. A French inventor, Cugnot, tried a steam-carriage at Paris in 1770, which went with so much force as to dash down a brick wall, and thereby deter other inventors. In 1782, Murdoch, exhibited a model of a steam-carriage; in 1784, Watt described his plans for another; and in 1786, Symington produced a model of a third. In the last-named year, too, Oliver Evans announced certain projects of the kind in the United States. In 1802, Messrs. Trevethick and Vivian patented a steam-carriage, planned on a much better principle than any that had preceded it; they adopted high-pressure steam, of which previous inventors had been afraid. The carriage was tried, but the ingenious patentees received very little encouragement, and soon turned their attention to railway matters. A long interval then passed without any new inventions in this kind of road-locomotion. When Telford and other engineers had improved the roads and highways, inventors were again induced to apply steam-power as a substitute for horse-power to road-vehicles. Bramah made a steam-carriage in 1821, on a plan patented by Julius Griffiths. Gordon invented one in 1822, which worked something like a squirrel in a cage, the engine being within a cylinder, which rolled along the ground; and another in 1824, which appeared to walk upon six iron legs.

Goldsworthy Gurney, Burstall, Hill, James, Hancock, Summers, Ogle, Heaton, Church, Dance, Field, Squire, Maceroni, Scott Russell, Hills, Sir James Anderson—all invented new forms of steam-carriage between 1824 and 1841. Some of these displayed great ingenuity, and attained a speed of 10 or 12 miles an hour on common turnpike roads. Sir Charles Dance ran such a carriage between Gloucester and Cheltenham in 1831, doing the 9 miles in 55 minutes; but the opposition of local interests put him down, after he had made 400 such trips without an accident, and carried a very large number of passengers. In the same year, Mr. Hancock began running his steam-carriage, called *The Infant*, regularly between London and Stratford; and some time afterwards, Mr. Scott Russell ran *his* invention between Glasgow and Paisley. All these three were passenger-vehicles which plied for traffic on the road. In the very numerous inventions from time to time brought forward, the passengers were in some cases seated in front of the engine and boiler; in others, they were seated behind; in others, the tank for water was placed beneath the passengers' feet; while in a fourth kind, there was a passenger-carriage, distinct from, but linked to, the steam-locomotive. None of the inventions, however, attained to commercial success, so many were the difficulties which beset them.

The last quarter of a century has exhibited inventions rather for heavy traction than for passenger steam-carriages. One of the most remarkable of the latter kind is that which the Earl of Caithness drove, in 1864, from Inverness to his seat near Thurso. It carried three or four persons, and ascended and descended very steep inclines without much variation of speed. As a question of profit or commercial advantage, the inventors of such engines now look to their employment on common roads, for dragging heavy loads. Numerous patents have been taken out, with this view, by Boydell, Bray, Clayton, Burrell, Fowler, Aveling, R. W. Thomson, and others. In Mr. Thomson's engines, or 'road steamers,' the wheels are encircled by a complete ring, or tire, of India-rubber, protected on the outside by a flexible sheath of steel plates. As engines for drawing very heavy weights, these have proved the most powerful yet invented, and several of them by 1874 were constantly at work in Glasgow, dragging enormously heavy castings and boilers from the workshops of the engineers to the railways or wharves. In ordinary work, however, the road steamers can hardly be said to have been a success. The expense connected with the renewal of the india-rubber tires, and the other parts worn by the constant jolting on common roads, has told very much against their adoption. Of traction engines with iron wheels, Fowler's and Aveling's are those most used. They are very simple in construction, and cheap in comparison to Thomson's, although not capable of doing the exceptionally heavy work we have just mentioned. Great endeavors are now being made to design an engine suitable for use upon tramway lines laid down on common roads, but as yet without complete success. Several acts of parliament have been passed to regulate the use of locomotives upon common roads. Their regulations at first were severely restrictive, framed apparently rather to discourage than to encourage enterprise. Now, however, that the engines are improved, and their use more understood by the public, the popular feeling against the engines, which caused this legislation, is rapidly disappearing.

It has been a favorite idea for many years with amateur and professional mechanicians to make a light carriage which could be used upon ordinary roads, and which should contain a steam-engine and boiler to propel itself. No doubt a self-propelling steam-carriage to carry only the weight of a passenger or two *can* be easily made, but its cost will be great in proportion to any service it can render.

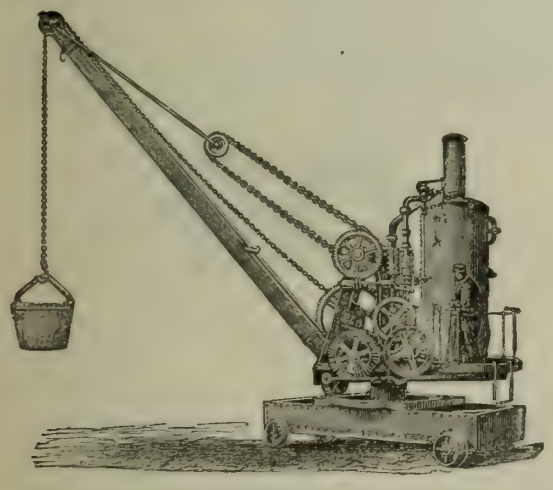
The true application of steam upon common roads is in the drawing of heavy loads which would otherwise require an inconveniently large number of horses. Engines for this purpose are called *traction engines*, and their use, notwithstanding determined, and too often ignorant, opposition, seems to be yearly on the increase. Traction-engines or road-locomotives are now made by all the chief makers of agricultural implements in England as well as in other countries. These are of different types, some being for drawing very heavy loads; some again for lighter work such as the drawing of a thrashing-machine from place to place over moderate gradients; these latter being also adapted for a variety of purposes for which a self-moving has been found to

* Cotterill, *Notes on the Theory of the Steam-engine*, page 9.

possess great advantages over an ordinary portable engine. Some recent forms of traction-engines have driving-wheels as large as 7 or 8 feet in diameter. An ingenious form of traction-engine, called by the inventor a *road-steamer*, was patented by the late Mr. R. W. Thomson, of Edinburgh, its most distinguishing feature being the use of thick india-rubber tires. These tires are simply rings of india-rubber, four or five inches thick, stretched over the rim of the wheel, and protected by a flexible circle of steel shoes from being damaged by stones, &c. The advantage of flexible tires is the greater adhesion (in proportion to weight) which they give to the engine, and the saving the machinery from shocks and jars. The great cost of these rubber tires is, however, a great hindrance to their being adopted.

Traction engines which are employed for such purposes as drawing heavy loads from quarries are found to entail great expense for the maintenance of the roads they traverse. But notwithstanding any drawbacks, road-engines are now used to a very considerable extent in Great Britain, chiefly for agricultural purposes. On the Continent and in America, however, the demand for them appears to be more limited.

STEAM-CRANE. Cranes worked either by steam or hydraulic power are now universal wherever much hoisting has to be done. It is often very convenient that a steam-crane should be movable, so that it may go to its work in cases where that arrangement is more convenient than the converse. For this purpose it is mounted on a plain railway truck, either of wood or iron, the truck being generally provided with clamps at the ends, by which it can be firmly secured to the rails when lifting weights. The balance construction, now universally adopted for portable cranes, was invented or suggested by the late Mr. R. W. Thomson, C.E., in 1856—its essential feature being the use of the boiler as a counterpoise to the weight to be lifted, as shown in the figure. The principal parts of a steam-crane are: 1. The boiler, which must be of some very simple construction, as it has so frequently to be worked with excessively dirty water; 2. The framing, which is generally made of cast-iron, and supports the boiler, the engine and gear, and the jib; 3. The engine (which has almost always two small cylinders, and is fitted with reversing gear), and the pinions, wheels, drums, &c., for the hoisting and other motions; 4. The 'jib' (either of wood or iron) over a pulley



in the top of which the chain passes, and the purpose of which is to enable the different objects to be lifted quite clear of the ground, and deposited, when necessary, on trucks, &c.; 5. The pillar, which is firmly attached to the truck, and which, passing upwards through the center of the frame, forms the pivot on which it turns round; 6. The truck itself, which supports the whole machine.

If the crane is stationary, the truck, of course, is not required, the bottom of the pillar being imbedded in masonry; and for large cranes the boiler is generally made separate from the machine itself, and sometimes the engines also. A portable balance steam-crane, like that in the engraving, is, when complete, fitted with the following motions: 1. Gear for hoisting, generally with two or more speeds, to be used according to the weight to be lifted; 2. Gear for raising or lowering the outer end of the jib; 3. Gear for slewing the jib (with boiler and frame attached to it); 4. Gear for propelling the truck along the rails. Our illustration shows a crane of this kind, made by Messrs. Chaplin and Co., of Glasgow. It will lift from 5 to 7 tons, according to the position of the jib. A number of very large steam-cranes with forked maleable-iron jibs have been erected in recent years by Messrs. J. Taylor and Co., of Birkenhead, at several of the great docks in England and Scotland. These will lift a weight of 50 or 60 tons, and are built on a strong and massive stone or brick foundation. They are constructed so as to sweep round an entire circle, but otherwise the jib is fixed.

STEAM-ENGINE. Steam-engines, in their infancy, were known as 'fire' (that is, *heat*) engines; and in point of fact the older term is the more correct, because the water or steam is only used as a convenient medium through which the form of energy which we call heat is made to perform the required mechanical operations. In modern engines, sufficient heat is added to the steam to raise it to a very high pressure and the excess of this pressure over the pressure opposed to it (either atmospheric pressure or the still lower pressure in a condenser) is both the cause and measure of the work done by the engine. In earlier machines, however, the steam was raised only to atmospheric pressure, and admitted into the engine only to be at once condensed by a jet of cold water. The excess of the atmospheric pressure above the pressure in the partial vacuum caused by the condensation was then the direct cause of work. Engines of this kind are not now used; they were called *atmospheric* engines. As a source of power, steam has many advantages over wind and water. It is independent of the weather, may be applied anywhere, affords a constant equable motion, and is capable of indefinite increase. Its invention, therefore, has caused a new era in the arts; and the revolution which it has brought about in industry of all kinds, as well as the influence it has had on civilization in general, and must yet have in a higher degree, are altogether incalculable.

The invention of steam as a moving power is claimed by various nations; but the first extensive employment of it, and most of the improvements made upon the steam-engine, the world indisputably owes to the English and the Americans. It would appear that as early as 1543, a Spanish captain named Blasco de Garay, showed in the harbor of Barcelona a steamboat of his own invention. It is most likely that Blasco's engine was on the principle of the Æolipile of Hero, invented 130 B.C., in which steam produces rotatory motion by issuing from orifices, as water does in Barker's Mill (q. v.). The preacher Mathesius, in his sermon to miners (Nurenberg, 1562), prays for a man who 'raises water by fire and air,' showing the early application of steam-power in Germany; and the German engineer, Sol. de Caus, in the service of the Elector Palatine in Heidelberg, describes, in his work, *Les Raisons des Forces Mouvantes avec Diverses Machines* (Frankf. 1615), a steam-machine, which was merely a contrivance for forcing the water contained in a copper ball through a tube by applying heat. An Italian engineer, G. Branca, invented, in 1629, a sort of steam windmill; the steam being generated in a boiler, was directed by a spout against the flat vanes of a wheel, which was thus set in motion.

In England, among the first notices we have of the idea of employing steam as a propelling force, is that contained in a small volume,* published in 1647, entitled *The Art of Gunnery*, by Nat. Nye, mathematician; in which he proposes to 'charge a piece of ordnance without gunpowder,' by putting water instead of powder, ramming down an air-tight plug of wood, and then the shot, and applying a fire to the breech 'till it burst out suddenly.' But the first successful effort was that of the Marquis of Worcester. In his *Century of Inventions*, the manuscript of which dates from 1655, he describes a steam-apparatus by which he raised a column of water to the height of 40 feet. This, under the name of 'Fire-waterwork,' appears actually to have been at work at Vauxhall in 1656.

Sir Samuel Morland, in 1683, submitted to Louis XIV. a project for raising water by means of steam, accompanying it with ingenious calculations and tables. The first patent for the application of steam-power to various kinds of machines was taken out in 1698 by Captain Savery. In 1699, he exhibited before the Royal Society a working model of his invention. His engines were the first used to any extent in industrial operations; they seem to have been employed for some years in the drainage of mines in Cornwall and Devonshire. The essential improvement in them over the older ones was the use of a boiler separate from the vessel in which the steam did its work. One vessel, in all former engines, had served both purposes. He made use of the condensation of steam in a close vessel to produce a vacuum, and thus raise the water to a certain height, after which the elasticity of steam pressing upon its surface was made to raise it still further in a second vessel.

In all the attempts at pumping-engines hitherto made, including Savery's, the steam acted directly upon the water to be moved without any intervening part. To Dr. Papin, a celebrated Frenchman, is due the idea of the *piston*. It was first used by him in a model constructed in 1690, where the cylinder was still made to do duty also as a boiler; but in an improved steam-pump invented

* The volume is in the possession of Mr. S. Holliday, to whom we are indebted for this fact.

about 1700 he used it as a diaphragm floating on the top of the water in a separate vessel, or cylinder, and the steam, by pressing on the top of it, forced the water out of the cylinder at the other end.

The next great step in advance was made about 1705 in the 'atmospheric' engine, conjointly invented by Newcomen, Cawley, and Savery. This machine held its own for nearly seventy years, and was very largely applied to mines, so that it will be worth while to give a somewhat more detailed description of it than of the others.

In this engine, which is shown in fig. 1, the previous inventions

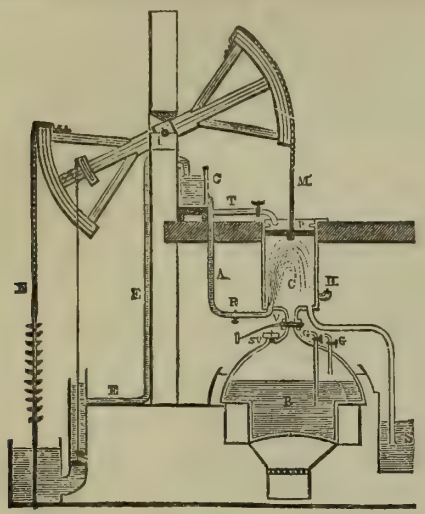


Fig. 1.

of the separate boiler, and of the cylinder with its movable steam-tight piston, are utilized, although in a new form. The 'beam,' which has ever since been used in pumping-engines, was used for the first time, and for the first time also the condensation of the steam was made an instantaneous process, instead of a slow and gradual one. Newcomen's engine was chiefly used, like all former sterm-engines, in raising water. To one end of a beam moving on an axis I, was attached the rod, N, of the pump to be worked; to the other, the rod, M, of a piston P, moving in a cylinder C, below. The cylinder was placed over a boiler B, and was connected with it by a pipe provided with a stop-cock V, to cut off or admit the steam. Suppose the pump-rod depressed, and the piston raised to the top of the cylinder—which was effected by weights suspended at the pump-end of the beam—the steam-cock was then turned to cut off the steam, and a dash of cold water was thrown into the cylinder by turning a cock R, on a water-pipe A, connected with a cistern C'. This condensed the steam in the cylinder, and caused a vacuum below the piston, which was then forced down by the pressure of the atmosphere, bringing with it the end of the beam to which it was attached, and raising the other along with the pump-rod. The cock was then turned to admit fresh steam below the piston, which was raised by the counterpoise; and thus the motion began anew.

The opening and shutting of the cocks was at first performed by an attendant, but subsequently a boy named Humphrey Potter (to save, it is said, the trouble of personal superintendence) devised a system of strings and levers by which the engine was made to work its own valves. In 1717, Henry Beighton, an F.R.S., invented a simpler and more scientific system of 'hand-gear,' which rendered the engine completely *self-acting*. During the latter part of the time that elapsed before Watt's discoveries changed everything, Smeaton brought Newcomen's engine to a very high degree of perfection. As the result of study and experiment, he made many improvements in it, in the form of the boiler, the proportions of the cylinder, &c. It was he, too, who invented the *cataract*, a very ingenious self-acting valve arrangement, which is still universally used in Cornish engines. It is worth mentioning that, in 1725, Leupold invented an engine in which steam of a higher pressure than that of the atmosphere was employed in the cylinder, but his engine possessed defects that prevented its practical use.

The next essential improvements on the steam-engine were those of Watt, which began a new era in the history of steam-power. The first and most important improvement made by Watt was the separate condenser, patented in 1769. He had observed that the jet of cold water thrown into the cylinder to condense the steam, necessarily reduced the temperature of the cylinder so much that a great deal of the steam flowing in at each upward stroke of the piston was condensed before the cylinder got back the heat abstracted from it by the spurt of cold water used for condensing the steam in the cylinder. The loss of steam arising from this was so great, that only about one-fourth of what was admitted into the cylinder was actually available as motive-power. Watt therefore provided a separate vessel in which to condense the steam, and which could be kept constantly in a state of vacuum, without the loss which arose when the cylinder itself was used as a condenser. This device, which now looks simple enough, was the greatest of Watt's inventions, and forms the foundation of his fame. His genius was such that in a few years he changed the steam-engine from a clumsy, wasteful, almost impracticable machine, into a machine practically the same as we now have.

The principal improvements since his time have been either in matters relating to the boiler; in details of construction consequent on our increased facilities, improved machinery, and greater knowledge of the strength of materials; in the enlarged application of his principle of expansive working; or in the application of the steam-engine to the propulsion of carriages and vessels. His principal inventions were: 1. The condensation of steam in a vessel separate from the cylinder, so as to avoid the cooling of the latter; 2. The use of a pump, called an 'air-pump,' to withdraw the condensed water, and mixed steam and air, from the condenser; 3. To surround the cylinder either with a steam-jacket, or with some non-conducting body, in order to prevent radiation of heat (these three, with others, were included in the specification of 1769); 4. To use the steam expansively in the way explained further on in this article (this was invented before 1769, but not published till 1782); and 5. The now universally used double-acting engine, and the conversion of the reciprocating motion of the beam into a rotary motion by means of a crank (both these were invented before 1778, the engine being patented in 1782, but the crank having before that date been pirated and patented by another). In 1784, Watt also patented and published his parallel motion, throttle-valve, governor, and indicator; all four of which are in substance still used.

It would be inconsistent with our limits to enter into any description of the constructive details of steam-engines; we can only afford to give a general notion of the way in which the motion is originated, and to explain the chief principles on which the motive-power and economy of engines depend. We shall consider the latter first, and may say that the article STEAM should be read as an introduction to what follows, as we must assume a familiarity with the statements there made.

The common mode of employing steam in an engine is by causing it to press alternately on the two surfaces of a movable diaphragm or piston enclosed in a fixed, steam-tight, cylindrical box. In fig. 2, A is the piston, and B a section of the box. The

Fig. 2.

piston, by means of a rod E, passing through the end of the box, is made to communicate motion to the rest of the machinery. The steam is first admitted to one end of the cylinder through an opening D, and forces the piston along to the other end. The current of steam from the boiler is then allowed to pass into the other end of the cylinder through the opening C, and forces the piston back again to its original position, and so on. But it is obvious that while this return-motion is going on, the steam previously admitted at D must be allowed some exit, or the piston could not be forced back. The manner of this exit constitutes the difference between the two principal classes of engines, according as the steam is allowed simply to rush out into the atmosphere, or is conducted into a separate vessel, and there 'condensed.'

The simplest way in which steam can be used in a cylinder is at the same time the most wasteful. It consists in filling each end of the cylinder alternately full of steam direct from the boiler, and having the full boiler pressure, and thus forcing the piston along in exactly the same way as that in which it would have to be forced were water the fluid used instead of steam. We have said this is wasteful; let us examine the reasons. If we imagine the cylinder to have a capacity of 7 cubic feet, then if it be filled entirely with steam from the boiler at 60 pounds pressure, it will contain just one pound-weight of steam.* The total heat in this pound of steam, as given in the table, is equivalent to 1171 thermal units.†

* These figures are near approximations only, as will be seen from the table in article STEAM.

† A 'thermal unit' is the quantity of heat necessary to raise, through 1° Fahr., the temperature of a pound of water at its temperature of max density—viz., 39·1 F., and may be considered, without much error, as the quantity of heat necessary to raise a pound of water 1° F., at any place on the thermometric scale.

When the piston A has reached the end of its stroke, the steam contained in the cylinder is thus in itself a great storehouse of work, for each of these thermal units is equivalent to 772 'foot-pounds' of mechanical energy. But instead of utilizing this force, at the moment when the cylinder is full of steam the opening C is put into communication with the boiler, the opening D with the atmosphere, and the steam immediately rushes out of the cylinder, and dissipates its contained energy through the air.

It must be remembered that although the steam, when allowed to go into the atmosphere, is immediately reduced to the pressure corresponding to the temperature of the air (which in ordinary cases would be only a fraction of a pound per square inch), still the full pressure of the atmosphere itself will always be acting on the back of the piston during its stroke; and that therefore, to find the force with which the piston is being pushed along, we must subtract that pressure from the steam pressure. On the one side of the piston will be the atmosphere with its uniform pressure of nearly 15 pounds per square inch, and on the other side the steam pressure of 60 pounds. The effective pressure thus will be 60—15, or 45 pounds per square inch only.
